Modern status of heavy quark sum rules in QCD

Stephan Narison

Abstract

We briefly report the modern status of heavy quark sum rules (HQSR) based on stability criteria by emphasizing the recent progresses for determining the QCD parameters ($\alpha_s$, $m_c$, $m_b$, and gluon condensates) where their correlations have been taken into account. The results:

$\alpha_s(M_Z) = 0.1181(16)(3)$,

$m_c(m_c) = 1286(16)$ MeV,

$m_b(m_b) = 4202(7)$ MeV,

$\langle \alpha_s G^2 \rangle = (6.49 \pm 0.35) \times 10^{-2}$ GeV$^4$, $\langle g_3 G_3 \rangle = (8.2 \pm 1.0) \times$ GeV$^2$

and the ones from recent light quark sum rules are summarized in Table 2. One can notice that the SVZ value of $\langle \alpha_s G^2 \rangle$ has been underestimated by a factor 1.6, $\langle g_3 G_3 \rangle$ is much bigger than the instanton model estimate, while the four-quark condensate which mixes under renormalization is incompatible with the vacuum saturation which is phenomenologically violated by a factor (2 ∼ 4). The uses of HQSR for molecules and tetraquarks states are commented.

Keywords: QCD spectral sum rules, QCD coupling $\alpha_s$, Hadron and Quark masses, QCD condensates.

1. Introduction

QCD spectral sum rules (QSSR) à la SVZ have been applied since 41 years to study successfully the hadron properties (masses, couplings and widths) and to extract some fundamental QCD parameters ($\alpha_s$, quark masses, quark and gluon condensates, ...).

In this mini-review, we concentrate on the determinations of the previous QCD parameters from heavy quark sum rules and shortly comment on the uses of these sum rules for extracting the masses and couplings of the molecules and tetraquark states. The present review complements the ones already presented in [6].

We emphasize that the analysis of the correlations of the previous QCD parameters as done in [7–13] leads to a noticeable improvement of their determinations and gives an understanding of the apparent discrepancy between some earlier estimates.

2. The heavy quark sum rules (HQSR)

As can be seen in the SVZ original papers [11, 2] and in the books [3, 4], the heavy quark sum rules are of the form of exponential / Borel / Laplace (LSR) sum rules and of their ratios:

$$\mathcal{L}(\tau, \mu) \equiv \lim_{Q^2, n \to \infty} \frac{\partial^n \hat{\Pi}}{(n-1)! (\partial Q^2)^n}$$

$$= \int_{M_b^2}^{\infty} dt \frac{1}{\pi} \text{Im} \Pi(t, \mu),$$

$$\mathcal{R}_n(\tau) = \frac{\mathcal{L}_{n+1}}{\mathcal{L}_n},$$

1References to original works, reviews and books prior 2004 can be found in the books and reviews [3, 4].
or of the $Q_0^2$-Moments sum rules (MSR) and their ratios:
\[
\mathcal{M}_n(Q_0^2,\mu) = \frac{1}{n!} \left( \frac{\partial}{\partial q^2} \right)^n \Pi_n(q^2, m_\gamma^2)_{|q^2 = Q_0^2} = \int_{\Delta m_0^2}^{\infty} \frac{dt}{(t + Q_0^2)^n} \frac{1}{\pi} \text{Im} \Pi_H(t, \mu) ,
\]
\[
r_{n/\pi + p}^\gamma = \frac{\mathcal{M}_n}{\mathcal{M}_{n+p}} : p = 1, 2, \ldots ,
\]
where $m_\gamma$ is the heavy quark mass, $\tau$ is the LSR variable, $Q_0^2 = 0, m_\gamma^2$, is a free chosen scale, $n$ is the degree of moments, $t_* is the threshold of the “QCD continuum” which parametrizes, from the discontinuity of the Feynman diagrams, the spectral function Im $\Pi_H(t, m_\gamma^2, \mu^2)$. $\Pi_H(t, m_\gamma^2, \mu^2)$ is the generic two-point correlator defined as:
\[
\Pi_H(q^2) = i \int d^4 x e^{-i q x} \langle 0 | T \mathcal{O}_H(x) \mathcal{O}_H(0) | 0 \rangle .
\]
$O_H(x)$ is the interpolating quark bilinear local current $\bar{\psi}_f \Gamma_{12} \psi$ for ordinary hadrons and four-quark $(\bar{\psi}_f \Gamma_{12} \psi_{gj})(\bar{\psi}_j \Gamma_{34} \psi_d)$ or diquark anti-diquark $(\bar{\psi}_f \Gamma_{12} \psi_{gj})(\bar{\psi}_j \Gamma_{34} \psi_d)$ local current for molecules or tetraquark states. $\Gamma_{ij}$ is any Dirac matrices which specify the quantum numbers of the corresponding hadronic state (and its radial excitations) which couples to the current through its decay constant:
\[
\langle 0 | \mathcal{O}_H(x) | H \rangle = f_H M^0_{H} ,
\]
where $d$ depends on the dimension of the current.

3. The SVZ - Expansion and beyond

According to SVZ, the RHS of the two-point function can be evaluated in QCD within the Operator Product Expansion (OPE) provided that $\Lambda^2 \ll Q^2 \approx -q^2, m_\gamma^2$. In this way, it reads:
\[
\Pi_H(q^2, m_\gamma^2, \mu) = \sum_{D=0,2,\ldots} C_D(q^2, m_\gamma^2, \mu) \langle O_D(\mu) \rangle ,
\]
where $C_D$ are calculable Wilson coefficients and $\langle O_D(\mu) \rangle$ are non-perturbative gauge invariant condensates of dimension $D$. The usual perturbative (PT) contribution corresponds to $D = 0$ while the quadratic quark mass corrections enter via $D = 1$. The asymptotic behaviour of the PT series is often expected to have an exponential behaviour (Borel sum) according to the large $\beta$ approximation and then alternate signs are expected to be seen at large orders of PT. However, the known calculated terms up to order $a_s^5$ of the vector correlator $D$-function do not yet show such properties. In Refs. [17-20], a phenomenological parametrization of these higher order terms due to UV-renormalons have been proposed which is quantified in terms of a tachyonic gluon mass squared. Its phenomenological value from $e^+e^- \rightarrow$ hadrons data [21], $\pi$-Laplace sum rule [17] and from an analysis of the lattice data of the pseudoscalar @ scalar two-point correlators [18] lead to the average [25]:
\[
(\alpha_s / \pi)^2 \simeq -(7 \pm 3) \times 10^{-2} \text{GeV}^2.
\]
The existence of this $D = 2$ term not present in the standard OPE (absence of gauge invariant $D = 2$ term) has raised some vigourous (unjustified and emotional) reactions though its contribution is tiny in the sum rule and $\tau$-decays [35] analyzes and that it has solved some paradoxical sum rule scale puzzles [18]. This $D = 2$ term is also seen in some AdS/QCD models [22-24]. However, this term is not of InfraRed origin like some other non-perturbative condensates but it is dual to the sum of higher order Ultra-Violet terms of the PT series as shown in [25]: better the series is known , lesser is the strength of this term which can vanish after some high order Ultra-Violet terms of the PT series. A such term is dual to a geometric sum of the coefficients of the PT series and is consistent with the values of the known coefficients.

Up to dimension-six ($D = 6$), one has successively the $(\bar{\psi} \psi)$ quark, $\langle \bar{\psi} \gamma^\mu G_\mu \psi \rangle$ and $\langle \bar{\psi} G^\mu G^\nu \psi \rangle$ gluons, $\langle \bar{\psi} G_{\mu \nu} \rangle \equiv \langle \bar{\psi} \gamma^\mu \gamma^\nu (\lambda_3 / 2) G_{\mu \nu} \psi \rangle$ and $g \langle \bar{\psi} G_{\mu \nu} \rangle$ mixed quark-gluon and the $g^2 \langle \bar{\psi} \gamma^\mu \gamma^\nu G_{\mu \nu} \psi \rangle$ four-quark condensates. The quantities $m(\bar{\psi} \psi)$ and the trace of the energy-momentum transfer: $\theta^\mu_\nu = m(\bar{\psi} \psi) / (1/4) \bar{\psi} (G^\mu)^{\rho \sigma} G_{\rho \sigma} G_{\mu \nu}$ are known to be $\mu$-independent where $\gamma, \beta$ are the quark mass anomalous dimension and Callan-Symanzik $\beta$-function.

The renormalization of higher dimension condensates have been studied in [26] where it has been shown that $g^4 \bar{\psi} \bar{\psi} G^\mu G^\nu G_\mu G_\nu$ does not mix under renormalization and behaves as $\langle \bar{\psi} \psi \rangle^{(1/3)}$, where $\beta_1 = -(1/2)(11 - 2n_f / 3)$ is the first coefficient of the $\beta$-function and $n_f$ is number of quark flavours. The quark-gluon mixed condensate usually parametrized as $g \langle \bar{\psi} G_{\mu \nu} \rangle \equiv M_0^2 \langle \bar{\psi} \psi \rangle$ mixes under renormalization and runs as $\langle \bar{\psi} \psi \rangle^{(1/3)}$ in the chiral limit $m = 0$. The scale $M_0^2$ has been estimated from light baryons [27-33] and heavy-light mesons [34]:
\[
M_0^2 = 0.8(2) \text{GeV}^2 .
\]
The four-quark condensate mixes under renormalization with some other ones which is not compatible with the vacuum saturation assumption used by SVZ. Its phenomenological estimate from $\tau$-decays [35]. $e^+e^- \rightarrow$
hadrons data [36], finite energy [17] and baryon [30–32] sum rules, leads to:

$$\rho G \equiv \langle g^3 f_{abc} G^3 \rangle / \langle \alpha_s G^2 \rangle = (8.2 \pm 1.0) \text{GeV}^2,$$

(9)

where \( \rho \) indicates the deviation from factorization.

A first step for the improvement of the estimate of the gluon condensate was the recent direct determination of the ratio of the dimension-six gluon condensate \( \langle g^3 f_{abc} G^3 \rangle \) over the dimension-four one \( \langle \alpha_s G^2 \rangle \) using HQSR with the value [10]–[12]:

$$\rho G \equiv \langle g^3 f_{abc} G^3 \rangle / \langle \alpha_s G^2 \rangle = 5.8(9) \times 10^{-4} \text{GeV}^2 : \rho \approx 2 \sim 4 .$$

(8)

5. Optimization criteria

As the LSR sum rule variable \( \tau \) and the degree \( n \) of MSR are free parameters, one has to define some robust criteria for extracting the QCD parameters or/and resonances masses and couplings from the sum rules.

Originally, SVZ have looked for a sum rule window where they requires more than 50% contribution of the resonance and less than 50% of the QCD continuum one which most of the sum rules practitioners continue to use. Later on using the example of the harmonic oscillator and the \( J/\psi \) channel, Bell-Bertlmann [15]–[16] have shown that, the optimal result for an approximate series, is obtained at the minimum or inflexion point of the ground state mass with respect to its \( \tau \)-variation (see various examples in e.g [3]–[4]). This criterion is more rigorous and improves the SVZ one as at the minimum or inflexion point, the SVZ requirement is automatically satisfied.

Later on, this criterion of \( \tau \)-minimum sensitivity has been extended to the one of the number \( n \) of moments [10]–[11]–[13], continuum threshold \( t \), [3]–[4] and PT subtraction scale \( \mu \) [45]–[46]–[49]–[52] where they are considered as external unphysical variables. We shall discuss some examples below.

6. Initial QCD input parameters

In the first iteration, the following QCD input parameters (mass in units of MeV) have been used:

$$\alpha_s(M_Z) = 0.325^{+0.08}_{-0.016} , \langle \alpha_s G^2 \rangle = (0.07 \pm 0.04) \text{GeV}^4.$$  

(10)

The central value of \( \alpha_s \) comes from \( \tau \)-decay [35]–[53]. The range covers the one allowed by PDG [54]–[55] (lowest value) and the one from our determination from \( \tau \)-decay (highest value) [35]. The values of \( \langle \alpha_s G^2 \rangle \) are the average from our recent determinations from charmonium and bottomium sum rules [10]–[11]. The value of \( \langle \alpha_s G^2 \rangle \) almost covers the range from different determinations mentioned in Table 1 of Ref. [7].

7. \( \overline{m}_c \) and \( \overline{m}_b \) from HQSR

\( J/\psi \) and \( \Upsilon \) systems have been used since the original SVZ papers for extracting the charm and bottom quark masses. However, in these pioneer works [3]–[4], the definition of the mass extracted from the analysis was ambiguous which has become clear after the use of the \( \overline{MS} \)-scheme running mass \( \overline{m}_{c,b}(\overline{m}_{c,b}) \) [56]. The most recent update of these determinations are summarized in Table 2 from [49] which we reproduce in Table[1]. These results are compiled in the PDG data [54].
Table 1: Values of $\overline{m}_c(\overline{m}_b)$ and $\overline{m}_t(\overline{m}_c)$ in units of MeV coming from our most recent QSSR analysis based on stability criteria. Some other determinations can be found in PDG [53].

| Masses | Values | Sources |
|--------|--------|---------|
| $\overline{m}_c(\overline{m}_b)$ | 1256(30) $J/\psi$ family Ratios of LSR [7] | |
|        | 1266(16) $M_{3b}-M_0$ Ratios of LSR [7] | |
|        | 1264(6) $J/\psi$ family MOM & Ratios of MOM [13] | |
|        | 1286(66) $M_D$ Ratios of LSR [47] | |
|        | 1286(16) $M_{BR}$ Ratios of LSR [49] | |
|        | 1266(6) Average [49] | |

| $\overline{m}_t(\overline{m}_c)$ | 4192(17) 't family Ratios of LSR [7] | |
|        | 4188(8) 't family MOM & Ratios of MOM [13] | |
|        | 4236(69) $M_B$ Ratios of MOM & & of LSR [47] | |
|        | 4213(59) $M_B$ Ratio of HQET-LSR [38] | |
|        | 4202(7) $M_{BR}$ Ratios of LSR [49] | |
|        | 4196(8) Average [49] | |

8. Correlation between $\overline{m}_c$ and $\overline{m}_b$ from $M_{BR}$

Figure 1: $M_{BR}$ as function of $\overline{m}_c(\overline{m}_b)$ for different values of $\overline{m}_c(\overline{m}_b)$, at the stability point $\mu=7.5$ GeV and for the range of $\tau$-stability values $\tau = 0.30 \pm 0.32$ GeV$^{-2}$.

9. Correlation between $\overline{m}_{c,b}$ and $\langle \alpha_s G^2 \rangle$

We show in Fig. 1 the correlation between $\overline{m}_c$ and $\overline{m}_b$ from the LSR analysis of $M_{BR}$ [49]. One can check that the numbers quoted in Table 1 satisfy this constraint. The correlation among $\overline{m}_c$, $\overline{m}_b$ and the gluon condensate $\langle \alpha_s G^2 \rangle$ has been studied in details in [7, 8] using the Laplace sum rule (LSR) in different ordinary charmonium and bottomonium channels. The advantage of the vector channels $J/\psi$ and 't channels are that one has complete data from $e^+e^- \rightarrow J/\psi$, 't, ..., For the other axial-vector (pseudo)scalar states, the simple duality ansatz : "one resonance" + QCD "continuum" gives a good description of the spectral function as tested from these $J/\psi$, 't, ... complete data (see previous quoted papers and books).

As an example we show in Fig. 2 the correlation between $\overline{m}_c$ and the gluon condensate $\langle \alpha_s G^2 \rangle$. We have used the initial inputs in Eq. [11] and the value:

$$\mu_c = (2.85 \pm 0.05) \text{ GeV},$$

(12)
of the subtraction point $\mu_c$ at the stability region for the charmonium $J/\psi$ and $\chi_c$ channels from LSR [7, 8]. This figure clearly shows that with the alone $J/\psi$ channel, one cannot fix accurately the value of the gluon condensate as it is sensitive to the input values of $\overline{m}_c$, where a fat band is observed. This feature explains the apparent discrepancy between different results in the literature where only the value from the $J/\psi$ channel has been used. Adding the $\chi_c$-channel in the analysis with a narrow band improves the determination of $\langle \alpha_s G^2 \rangle$ (see Fig. 2), which leads at the intersection region to:

$$\langle \alpha_s G^2 \rangle = (8.5 \pm 3.0) \times 10^{-2} \text{ GeV}^4,$$

(13)

$$\overline{m}_c(\overline{m}_t) = (1256 \pm 30) \text{ MeV}.$$ (14)

Using the average value of $\overline{m}_c(\overline{m}_t)$ in Table 1, one can deduce from Fig. 2 the improved estimate:

$$\langle \alpha_s G^2 \rangle = (7.35 \pm 0.65) \times 10^{-2} \text{ GeV}^4.$$

(15)

As discussed in Ref. [7], the inclusion of an estimated N3LO PT and NLO gluon condensates corrections give negligible contributions. This result can be compared with the average of different sum rules determinations prior 2017 (see Table 1 of [7]):

$$\langle \alpha_s G^2 \rangle = (6.25 \pm 0.45) \times 10^{-2} \text{ GeV}^4.$$

(16)

This result confirms the conclusion of [15, 16, 37] stating that the SVZ value 0.04 GeV$^4$ has been underestimated by about a factor 2.

10. Correlation between $\overline{m}_b$ and $\alpha_s$

Some other correlations of $\overline{m}_{c,b}$ with $\langle \alpha_s G^2 \rangle$ have been also studied by Ref. [7] in different channels but
have given weaker constraints than the one presented above. Instead, these channels have provided improved estimates of \(m_{c,b}\) with the results in Table 1. In the bottomonium channel, \(\bar{m}_b\) is instead correlated to \(\alpha_s\) as \(\langle \alpha_s G^2 \rangle\) gives a relatively smaller correction than in the case of charmonium. We show this correlation in Fig. 4 where on can deduce that, for given values of \(\alpha_s\), one can constrain the one of \(\bar{m}_b\). The value:

\[
\mu_b = (9.5 \pm 0.5) \text{ GeV}, \tag{16}
\]

at the \(\mu\)-stability region has been used.

11. \(\alpha_s\) and \(\langle \alpha_s G^2 \rangle\) correlation from \(M_{\chi_{c(0)b}} - M_{\eta_{c(0)b}}\)

The correlation between \(\alpha_s\) and \(\langle \alpha_s G^2 \rangle\) is more pronounced from the analysis of the \(M_{\chi_{c(0)b}} - M_{\eta_{c(0)b}}\) mass-splittings. In doing a such analysis, first, it has been checked that the LSR reproduces accurately the absolute masses of the (pseudo)scalar states \(\eta_{c(0)b}\) and \(\chi_{c(0)b}\) in [7] [8]. Second, the mass-splittings have been extracted directly from the sum rules while the Double Ratio of LSR [14] [57] has not been used because each individual mass sum rules do not optimize at the same value of \(\tau\). The effect due to \(\bar{m}_{c,b}\) and to \(\mu\) in the stability regions induce respectively an error of about \((1 \approx 2)\) MeV and \(8\) MeV. The largest effects are due to the changes of \(\alpha_s\) and \(\langle \alpha_s G^2 \rangle\). We show their correlations in Fig. 4. We have runned the value of \(\alpha_s\) from \(\mu_c = 2.85\) GeV to \(M_t\) in the charm channel and from \(\mu_b = 9.5\) GeV to \(M_t\) in the bottom one where the values of \(\mu\) correspond to the scales at which the sum rules have been evaluated:

\[
\alpha_s(2.85) = 0.262(9) \sim \alpha_s(M_t) = 0.318(15) \sim \alpha_s(M_Z) = 0.1183(19)(3),
\]

\[
\alpha_s(9.50) = 0.180(8) \sim \alpha_s(M_t) = 0.312(27) \sim \alpha_s(M_Z) = 0.1175(32)(3). \tag{17}
\]

The last error is due to the running procedure. We have requested that the method reproduces within the errors the experimental mass-splittings by about \((2 \approx 3)\) MeV. The geometric mean of the two previous values of \(\alpha_s\) is:

\[
\alpha_s(M_t) = 0.317(15) \sim \alpha_s(M_Z) = 0.1181(19)(3), \tag{18}
\]

which is (surprisingly) in a very good agreement with the world average [54] [55]:

\[
\alpha_s(M_Z) = 0.1181(11). \tag{19}
\]

We also show in Fig. 5 the running of the world average where we put the two determinations obtained at two different scales \(\mu_c = 2.85\) and \(\mu_b = 9.5\) GeV.

Adding into the analysis the range of input \(\alpha_s\) values given in Eq. 11 (light grey horizontal band in Fig. 4), one
can deduce stronger constraints on the value of \( \langle \alpha_s G^2 \rangle \):

\[
\langle \alpha_s G^2 \rangle = (6.39 \pm 0.35) \times 10^{-2} \text{ GeV}^4. \tag{20}
\]

Combining the previous values in Eqs. [14] [15] and [20] one obtains the new sum rule average:

\[
\langle \alpha_s G^2 \rangle_{\text{average}} = (6.49 \pm 0.35) \times 10^{-2} \text{ GeV}^4, \tag{21}
\]

where we have retained the error from the most precise determination in Eq. [20] instead of the weighted error of 0.25. This result definitely rules out some eventual lower and negative values quoted in Table 1 of Ref. [7].

12. QCD parameters from QSSR

We compile in Table 2 the recent values of the QCD parameters obtained from heavy and light quarks QCD spectral sum rules within stability criteria. We have introduced the renormalization group invariant light quark parameters \( \hat{m}_q \) and \( \hat{\rho}_q \) [3] [58] :

\[
\hat{m}_q (\mu) = \frac{\bar{m}_q}{(\log \mu / \Lambda)^{2 - \rho_q}} (1 + \rho_m),
\]

\[
\langle \bar{\psi} \psi \rangle (\mu) = \frac{\bar{\rho}_q}{(\log \mu / \Lambda)^{2 - \rho_q}} / (1 + \rho_m), \tag{22}
\]

with : \( \rho_m = 0.8951 a_s + 1.3715 a_s^2 + 0.1478 a_s^3 \) for \( n_f = 3 \) light flavours [3] [59], where \( \bar{m}_q \) and \( \langle \bar{\psi} \psi \rangle \) are the running mass and running condensate and \( a_s \equiv \alpha_s / \pi \). We have not considered the values of the light quark masses and condensates when the instanton effect is included in the SVZ-expansion. The corresponding results are also disfavoured by lattice calculations [60].

13. HQSR for molecules / four-quark states

Within the last ten years, HQSR have been often used for extracting the masses and couplings of the molecules and tetraquark states from two-point functions built with quartic quark or diquark anti-diquark currents or their widths using vertex or light cone sum rules. Though the phenomenological results are quite successful, there are general comments on the existing works in the literature which reminds the early days of the SVZ sum rules:

– The analysis is often done at LO of perturbation theory where the definition of the heavy quark mass which plays a crucial role is ambiguous. The common preferred choice of different authors is the running \( MS \) running mass which is not justified at all without adding radiative corrections which are not easy to calculate. An exception is the series of works in [51] [52] where the factorised NLO contributions have been considered.

| Parameters | Values | Sources | Ref. |
|------------|--------|---------|-----|
| Heavy | \( \alpha_s (M_Z) \) | 0.1181(16)(3) | \( M_{\psi, \chi} \rightarrow M_{\psi} \) [7][8] |
| | \( \bar{m}_q (\bar{m}_q) \) [MeV] | 1266(6) | \( D, B, B_s \) (see Table 1) |
| | \( \bar{m}_b (\bar{m}_s) \) [MeV] | 4200(8) | \( B, B_s \) (see Table 1) |
| | \( \langle \alpha_s G^2 \rangle \) [GeV^4] | 6.49(35)10^{-2} | Light-Heavy [7], this review |
| | \( \langle g^2 G^4 \rangle / \langle \alpha_s G^2 \rangle \) | 8.2(1.0)[GeV^2] | J/\psi [10][12] |
| Light | \( \bar{m}_q \) [MeV] | 253(6) | Light [3][4][61][62] |
| | \( \langle \bar{\psi} \psi \rangle (2) \) [MeV] | 1048 ± 7 | – – |
| | \( \kappa = \langle \bar{s}s \rangle / \langle \bar{d}d \rangle \) | 0.74(6) | Light-Heavy [3][4][61][62] |
| | \( m_u \) [MeV] | 3.05 ± 0.32 | – – |
| | \( m_d \) [MeV] | 6.10 ± 0.57 | – – |
| | \( m_s \) [MeV] | 114(6) | – – |
| | \( m_s (2) \) [MeV] | 2.64 ± 0.28 | – – |
| | \( m_s (2) \) [MeV] | 5.27 ± 0.49 | – – |
| | \( m_s \) (2) [MeV] | 98.5 ± 5.5 | – – |
| | \( M^2_s \) [GeV^2] | 0.8(2) | Light-Heavy [3][4][61][62] |
| | \( \rho \rightarrow (\phi \psi) \tau \) \( \times 10^4 \) | 5.8(9) [GeV^6] | Light-\( \tau \)-decay [28][29][32][47] |

Table 2: QCD parameters from heavy and light quarks QSSR (MOMents, LSR and ratios of sum rules) within stability criteria. The running light quark masses and condensates have been evaluated at 2 GeV.

– One also notice the inflation of including higher dimension condensates (sometimes until D=12) which can be a good point. However, one should notice that only a class of diagrams have been calculated and that these high dimension condensates mix under renormalization [26] which is incompatible with the vacuum saturation often used to estimate them. The simple typical example is the four-quark condensates discussed in the introduction which mix under renormalization where a violation of the vacuum saturation by a factor 2 ~ 4 has been observed from a fit to the data.

– In most papers, the optimization procedure based on the sum rule window of SVZ remains handwaving as the authors have to introduce some inaccurate criteria like larger than 50% contribution for the ground state and smaller than 50% for the QCD continuum which, often, is not properly taken into account in the error analysis. Besides, this point the error analysis is often done in a sloppy way and not in details such that the error is difficult to be appreciated and to be checked.

– Many authors continue to use old estimates of the QCD parameters by SVZ which (to my opinion) SVZ themselves will not consider seriously at present. One should be aware that a lot of efforts to improve the values of these parameters and the field during many
decades have been done and should not be ignored. Indeed, reading most of the present papers, one has the impression that no progress on the improvement of the method has been done since its discovery and the clock has stopped in 1979.

14. Conclusions

We have shortly reviewed the modern status of heavy quark sum rules (HQS) where we have emphasized the progresses on the determinations of the QCD parameters (quark masses, gluon condensates and QCD coupling $\alpha_s$) which have been achieved thanks to the analysis of the correlations among these parameters.

We have also commented the present uses of HQS for exotic hadron molecules and four-quark states.

To my personal opinion, QCD spectral sum rules can still have a long lifetime for studying successfully the properties of hadrons and for extracting the QCD parameters, However, provided we continuously improve it by doing a more careful job!
