Abstract

Background
The study aimed to estimate the prevalence and correlates of underweight and overweight/obesity among adults in Afghanistan.

Methods
National cross-sectional survey data of 3,779 persons aged 18–69 years were analysed. Multinomial logistic regression was used to estimate factors associated with underweight and overweight/obesity relative to normal weight.

Results
In all, 7.8% of the study sample was underweight (BMI < 18.5 kg/m²), 49.5% had normal weight (BMI 18.5–24.9 kg/m²), 25.5% overweight (25.0–29.9 kg/m²), and 17.2% obesity. In adjusted multinomial logistic regression, factors negatively associated with underweight were male sex (Adjusted Relative Risk Ratio-ARRR: 0.55, Confidence Interval-CI: 0.32–0.95). Factors positively associated with overweight/obesity were aged 30–44 years (ARRR: 1.92, CI: 1.46–2.53) and aged 45–69 years (ARRR: 1.49, CI: 1.05–2.11) (compared to 18–29 years) (ARRR: 1.28, CI: 1.14–2.18), hypertension (ARRR: 2.69, CI: 1.88–3.85), type 2 diabetes (ARRR: 1.81, CI: 1.15–2.86), and raised cholesterol (ARRR: 2.04, CI: 1.41–2.95).

Conclusion
Almost one in ten adult respondents were underweight and more than two in five were overweight/obese, confirming a dual burden of malnutrition in Afghanistan.

Introduction
Worldwide, among adults, the prevalence of undernutrition (18.5 < kg/m²) was 8.8% among men and 9.7% among women, and the prevalence of obesity (BMI ≥ 30 kg/m²) was 10.8% among men and 14.9% among women [1]. In the Eastern Mediterranean region, a high average prevalence of overweight/obesity (51%) has been reported [2]. In local community surveys in urban centres in Afghanistan, the following proportions of body weight status have previously been shown: in Kabul City (≥ 40 years, in 2011–2012), underweight 1.1% and overweight/obesity 69.3% [3], in Kabul (25–70 years, in 2015), 57.6% overweight/obesity [4], in Jalalabad (25–65 years, in 2013) underweight 6.1% [5] and overweight/obesity 57.4% [6], and in Kabul, Balkh, Hirat, Nangarhar and Kandahar (25–70 years, during 2013–2015) overweight/obesity was 52.7% [7]. In a national study among women 15–49 years in Afghanistan, the prevalence of underweight was 8.6% [8]. To our knowledge, there are no national adult body weight status data in Afghanistan.

In the Eastern Mediterranean region, the prevalence of overweight/obesity among adults ranged from 25–81.9% [9]. In Iran, the prevalence of underweight was 5.9% and 49.9% had overweight/obesity (15–65 years, in 2004–2005) [10], in Iraq (≥ 15 years, in 2015) underweight 3.6% and overweight/obesity 65.7% [11], in Jordan overweight or obesity (BMI ≥ 25 kg/m²) was 77.2% among men and 74.5% among women (≥ 18 years; 2017) [12], in Morocco underweight was
5.6% and overweight/obesity 56.1% (≥ 18 years; 2017) [13], and in Palestine (18–64 years, 1999–2000) underweight was 1.5% and overweight/obesity 62.4% [14].

Both undernutrition and overnutrition in adulthood have been linked to various negative health effects, including morbidity and mortality [15, 16]. As reviewed [17], sociodemographic factors associated with adult underweight may include female sex, younger and older age, lower socioeconomic status, and residing in rural areas. Health variables associated with adult underweight may include poor diets, smoking, and not having chronic conditions. As reviewed [17] sociodemographic factors associated with overweight/obesity include female sex, increasing age, higher socioeconomic status, and urban residence, and health variables associated with overweight/obesity may include, poor diet, physical inactivity, not smoking, diabetes, dyslipidaemia and hypertension. Afghanistan has a high prevalence of undernutrition in children (19.1% in 2018) under the age of five [8, 18], which may affect adult weight status. Afghanistan is a low income country, its living standards are among the lowest in the world, has a population of 36.6 million, life expectancy at birth was 52.8 years, and an adult literacy rate of 43% (55.5% among men and 29.8% among women [18]. The study aimed to estimate for the first time the national prevalence and correlates of underweight and overweight/among adults in Afghanistan.

**Methods**

This is a secondary analysis conducted using nationally representative population-based and cross-sectional data from the “2018 Afghanistan STEPS survey” [19]. The 2018 Afghanistan STEPS survey data and more detailed sampling methods can be accessed [20]. Briefly, a multistage cluster sampling was used to generate a nationally representative sample of adults aged 18–69 years. Stage 1 or primary sampling units were 55 districts, followed by villages or blocks (secondary sampling units), and households (tertiary sampling units). One person from each household was randomly selected [20]. In total, 3,956 persons aged 18–69 years were potentially eligible in this study. However, 177 women were excluded as they had indicated to be pregnant during the study so that 3,779 participants were included in the final data analysis. The study instrument was translated to Pashto and Dari and piloted [20]. The study was approved by the Ministry of Public Health Ethics Board, and written informed consent was obtained from participants [20].

**Measures**

Anthropometric measurements were taken by trained healthcare staff in a safe and secure area; height and weight were measured using a portable electronic weighing scale and measuring inflexible bars [20]. Body Mass Index (BMI) was classified as “<18.5kg/m² underweight, 18.5-24.4kg/m² normal weight, 25-29.9kg/m² overweight and ≥ 30 kg/m² obesity” [21].

*Hypertension or raised blood pressure* (BP) was defined as “systolic BP ≥ 140 mm Hg and/or diastolic BP ≥ 90 mm Hg or where the participant is currently on antihypertensive medication.” [22]. BP was measured with a calibrated sphygmomanometer after participants had been seated at least for 15 minutes, and three minutes in between readings. Of the three BP measurements, the last two readings were averaged [20].

*Diabetes* was defined as “fasting plasma glucose levels ≥ 7.0 mmol/L (126 mg/dl); or using insulin or oral hypoglycaemic drugs; or having a history of diagnosis of diabetes” [23].

History of *cardiovascular disorder* was asked with questions on having had a heart attack and stroke (Yes, No) [20].
Health risk behaviour variables comprised alcohol use, exposure to secondary smoke, smoking status, dietary behaviour (fruit and vegetable servings/day and number of meals outside home in the past week), and sedentary behaviour (≥ 8 hours/day [24]), and “low, moderate or high physical activity based on the Global Physical Activity Questionnaire” [25].

Sociodemographic information included age, sex, highest educational level, number of adult household members, and residence status [20]. Household crowding has been found to have an inverse relationship with socioeconomic status [26].

Data analysis

All statistical procedures were adjusted for complex sample design and conducted with “STATA software version 13.0 (Stata Corporation, College Station, TX, USA)”. The data were weighted “to make the sample representative of the target population in Afghanistan (by sex and by age group: 18–29, 30–44, 45 and over).” [20]. Chi-square test calculated differences in proportions. Multivariable multinomial logistic regression was used to estimate predictors of underweight and overweight/obesity (with normal body weight forming the reference category). Variables significant at $p < 0.1$ were included in the final model. No multi-collinearity was detected. Missing data were excluded from the analysis. $P < 0.05$ was considered significant.

Results

Sample and body mass index information

The sample consisted 3,779 individuals aged 18–69 years (median age: 35 years, 24–48 interquartile range), and 55.9% were male. Almost half of the participants (47.2%) were living with five or more adult household members, 59.0% had no formal education, and 42.4% lived in rural areas. In all, 7.8% of the study sample was underweight (BMI < 18.5 kg/m²), 49.5% had normal weight (BMI 18.5–24.9 kg/m²), 25.5% overweight (25.0–29.9 kg/m²), and 17.2% obesity. Further sample details are shown in Table 1 (see Table 1).

## Multinomial logistic regression for underweight and overweight/obesity

In adjusted multinomial logistic regression, factors negatively associated with underweight were male sex (Adjusted Relative Risk Ratio-ARRR: 0.55, Confidence Interval-CI: 0.32–0.95). Factors positively associated with overweight/obesity were aged 30–44 years (ARRR: 1.92, CI: 1.46–2.53) and aged 45–69 years (ARRR: 1.49, CI: 1.05–2.11) (compared to 18–29 years) (ARRR: 1.28, CI: 1.14–2.18), hypertension (ARRR: 2.69, CI: 1.88–3.85), type 2 diabetes (ARRR: 1.81, CI: 1.15–2.86), and raised cholesterol (ARRR: 2.04, CI: 1.41–2.95) (see Table 2).

| Variable (#missing values) | Sample | Normal weight | Underweight | Overweight | Obesity | p-value |

RRR = Relative Risk Ratio; CI = Confidence Interval
In this national 2018 Afghanistan STEPS survey, the prevalence of underweight (7.8%) was higher than in Kabul City (≥40 years, in 2011–2012) (1.1%) [3], in Jalalabad (25–65 years, in 2013) (6.1%) [5], in Iran 15–65 years, in 2004–2005) (5.9%) [10], in Iraq (≥15 years, in 2015) (3.6%) [11], in Morocco (≥18 years; 2017) (5.6%) [13], and Palestine (1.5%, 18–64 years, 1999–2000) [14], but similar to a national study among women (15–49 years, 8.6% vs 9.1% in this study) in Afghanistan [8], and the global prevalence of underweight (8.8% among men and 9.7% among women) [1]. The found prevalence of overweight/obesity (42.7%, ≥25.0 kg/m²) in this study is lower than the prevalence rates found in urban centres in Afghanistan, e.g., in Kabul City (69.3%, ≥40 years, in 2011–2012) [3], in Kabul (57.6%, 25–70 years, in 2015) [4], in Jalalabad (57.4%, 25–65 years, in 2013) (57.4%) [6], and in Kabul, Balkh, Hirat, Nangarhar and Kandahar (52.7%, 25–70 years, during 2013–2015) [7], in Iran (59.3%, 2016) [27], in Iraq (65.7%, ≥15 years, in 2015) [11], in Morocco (56.1% ≥18 years; 2017) [13], Palestine (62.4%, 18–64 years, 1999–2000) [14], and in Jordan (>75%, ≥18 years; 2017) [12], but higher than global estimates (10.8% of men and 14.9% of women obesity) [1].

Findings show the double burden of undernutrition (7.8%) and overnutrition (42.7%, ≥25 kg/m²) in the low-income country, Afghanistan. The co-existence of undernutrition (15.6%) and overnutrition (18.0%) has also been found in low-income countries in the Asia Pacific region [28]. The trend in the reduction of underweight and increase of overweight/obesity [1, 28] seems to be confirmed in this study in Afghanistan. “Rapid dietary and lifestyle transition it is the leading direction of dual burden toward overnutrition increase and diet-related NCDs” [28, 29]. In addition, it is possible that the high prevalence of undernutrition in children under the age of five in Afghanistan [8] has led to increased overnutrition in adulthood [30]. Increased efforts on policy initiatives and lifestyle changes are needed in Afghanistan to combat the double malnutrition burden.

The the prevalence of underweight was the highest among 18 to 29 year-olds (8.9%) and among women (9.1%), which was also found in previous studies [31–33], and may be attributed to food insecurity, in particular among young women [8, 34]. Akseer et al. [8] showed that younger adolescent mothers (<20 years) are more underweight than older mothers (20–49 years) in Afghanistan, attributing this to increased mother-child nutritional demands. Some previous research showed an association between lower socioeconomic status and underweight [17, 35, 36], but this study did not find this. One possible reason for this nonsignificant finding may be related to the measurement of economic status, which in this study was limited to the number of adult household members.

In bivariate analysis, obesity was higher in women (23.7%) compared to men (12.1%), which is in line with previous studies [5, 35, 36]. Consistent with previous research [7, 35, 36], overweight/obesity increased with age. While some previous studies [5, 35–37], found an association between higher economic status (less household crowding), education, and residing in urban areas and having overweight/obesity, this survey did not show significant associations. Similar results of a non-association between education, income, and job categories with overweight/obesity in adults in Kabul [7]. It is possible that educational level did not impact on body weight status because of the high proportion of the study population (59.0%) had no formal education. Of concern is as well that 32.3% of young people aged 18–29 years were already overweight or obese, showing that a large proportion of overweight/obesity is already established in early adulthood. Therefore, obesity interventions starting in childhood or adolescents should be prioritized in Afghanistan [38].

This study did not find an association between dietary behaviour (inadequate fruit and vegetable intake and having meals outside home) and underweight as well as overweight or obesity, unlike some previous research [17, 39, 40]. This study lacked to assess other dietary behaviours, such as frequent snaking, skipping breakfast, eating high amounts of processed or fast food, and high intake of sugary beverages, which may have been responsible for a higher rate of overweight/obesity [9, 41].
In agreement with previous studies [37–39, 42, 43], this study showed in bivariate analysis that physical activity was inversely and high sedentary behaviour was positively associated with overweight/obesity. Unlike some previous research [5, 38, 42], this study showed no (negative) association between current tobacco use and the prevalence of overweight/obesity. As shown previously [5–7, 38, 44, 45], we found an association between NCDs (hypertension, diabetes, and raised cholesterol) and overweight/obesity. This result emphasizes the fact that adults in Afghanistan suffer from several NCD risk factors at the same time [6], calling for multiple risk factor interventions [5, 7].

Implementing preventive interventions, such as programmes improving a healthy diet, appropriate food policies, promotion of physical activity and interrupting sedentary behaviour, and community awareness campaigns may help in ameliorating the high burden of overweight and obesity. The evaluation of experimental weight reduction interventions is recommended as future research to fine-tune intervention strategies in Afghanistan.

**Study Limitations**

Apart from physical and biomedical measures self-reported questionnaire data may have suffered from biased responses. Another limitation was the cross-sectional nature of the survey, which does not allow for causative conclusions. Some variables, such as more details on dietary behaviour, should be included in future studies.

**Conclusion**

The study found in the 2018 adult national Afghanistan STEPS survey that almost one in ten adult participants were underweight and more than two in five were overweight/obese. Several risk factors, including female sex for underweight and older age, hypertension type 2 diabetes, and raised cholesterol for overweight/obesity were identified, which can be targeted in interventions.

**Declarations**

All methods were carried out in accordance with relevant guidelines and regulations.

**Ethics approval and consent to participate**

The study was approved by the Ministry of Public Health Ethics Board, and written informed consent was obtained from participants [20].

**Consent for publication**

Not applicable

**Availability of data and materials**

“The data for the current study are publicly available at the World Health Organization NCD Microdata Repository (URL: https://extranet.who.int/ncdsmicrodata/index.php/catalog).”

**Competing interests**

The authors declare that they have no competing interests.

**Funding**

The analysis received no funding
Authors’ contributions

“All authors fulfil the criteria for authorship. SP and KP conceived and designed the research, performed statistical analysis, drafted the manuscript, and made critical revisions of the manuscript for key intellectual content. All authors read and approved the final version of the manuscript and have agreed to the authorship and order of authorship for this manuscript.”
