Abstract

**Background:** Podoconiosis is entirely preventable, non-communicable disease with high potential of elimination. One of the pillars for elimination of podoconiosis is morbidity control and management. Therefore, the present study was aimed to assess the knowledge, attitude, practices and associated factors of health professionals towards podoconiosis cause, prevention and treatments.

**Methods:** facility based cross-sectional study was conducted. The source population was all health professionals currently working in public health facilities. The final estimated sample size was 349. A pretested self-administrated structured questionnaire was used to collect the data. The data were coded, entered, and cleaned by using Epi.info version7, and analyzed by using SPSS version 20.

**Result:** a total of 320 health professionals were participated in the study. Sixty eight (23.1%) health professionals had poor knowledge towards podoconiosis. Seventy (21.9%) responded as podoconiosis is infectious disease. Profession, address of health facility, service year and attitude of participants became significantly associated with knowledge towards podoconiosis. More than half (56%) had favorable attitude towards podoconiosis patients. Knowledge score (95%CI: 1.389, 4.059, p-value= 0.002) was the independent predictor for attitude status. Very few (11.6%) respondents ever treated podoconiosis patients. Age group 45 years old and above and training on LMMDP was significantly associate with practice, (AOR=17.345; 95%CI: 4.62, 65.119) and (AOR=7.385; 95%CI: 2.5, 21.797), respectively.

**Conclusion:** Despite, high percent of good knowledge and favorable attitude of health professionals towards podoconiosis, practice of study subjects was very low. In-service trainings will be given for health professionals to improve practice. In podoconiosis endemic districts hygiene supplies and other referencing materials should be made available for podoconiosis case management.

1. **Background**

Neglected tropical diseases (NTD) affected more than one billion people globally and World Health Organization (WHO) African Region accounts about half of this global burden, which are greatly predominant in tropical and subtropical regions and affect mainly the low income and impoverished communities. Neglected tropical diseases are identified by their slowly evolving symptoms that often lead to devastating complications. By impairing the physical and intellectual capacities of the affected persons, these diseases perpetuate the cycle of poverty and negatively affect socioeconomic development\(^1\).

Podoconiosis, endemic non-filarial elephantiasis, is one of the neglected tropical diseases which is caused by prolonged exposure of barefoot to red clay soil of volcanic origin\(^2\). It affects the poorest community in the world, but it is easily preventable and treatable by using simple practical measures like regular and consistent wearing of proper shoes and washing their feet/foot hygiene making it as a norm \(^3\).

The disease affects men and women equally in most societies. Most of the community based studies had shown that the onset of clinical signs and symptoms happen in the first and second decades and gradual
increase in the podoconiosis prevalence up to the sixth decades. People who do not wear shoes regularly due to poverty or other cultural reasons are at higher risk for podoconiosis\textsuperscript{4}.

Podoconiosis causes bilateral yet asymmetrical leg swelling with lie on top firm nodules. Early onset symptoms may include itching, tingling, widening of the forefoot, and swelling which then advance to soft edema, skin fibrosis, papillomatosis, and nodule formation resembling moss, giving rise to the disease's alternate name of "mossy foot" in some regions of the world. As with other form of lymphedema, chronic disease can lead to rigid toes, ulceration, and bacterial super infection. During acute episodes of adenolymphangitis, patients may develop fevers, extremity warmth, redness, and pain. These episodes are extremely debilitating and account for many days of activity and productivity loss each year\textsuperscript{5}.

Endemic non-filarial elephantiasis or podoconiosis has severe social, economic and health consequences. According to the study conducted in Ethiopia, Wolayta zone revealed that the annual economic cost of the disease in an area with 1.7 million people was more than 16 million US dollars. When extrapolated to the national population, this finding reflects a corresponding cost of more than 200 million US dollars. People affected with podoconiosis were found to lose 45\% of their economically productive time because of illness associated with the disease. Majority of people living with podoconiosis in Ethiopia experience an episode of acute inflammation that may be triggered by bacterial, viral or fungal infection, at least once per year. Such type of acute attacks is characterized by hot, painful and reddened swelling. Since podoconiosis patients become bedridden during such attacks, it leads to loss of productivity\textsuperscript{6}.

More recently a systemic review on global epidemiology on podoconiosis conducted by Kebede Derib and his colleagues reported that the overall podoconiosis prevalence ranges from 0.10–8.08\% globally. The highest prevalence was in African region with substantially higher in adults than in children and adolescents. Their report showed that the prevalence of podoconiosis in Cameroon is 8.08\%, 7.45\% in Ethiopia, 4.52\% in Uganda, 3.87\% in Kenya and 2.51\% in Tanzania\textsuperscript{7}.

Although podoconiosis has severe social stigma, physical disability and economic unproductivity, the disease is neglected by global community. Most studies shown that podoconiosis is the common public health problem in African regions which affects mostly poorest community of the tropics with the highest prevalence. Majority of studies conducted, indicates that podoconiosis remains unrecognized in most governmental and non-governmental organizations\textsuperscript{8}.

Even though the public health importance and prevalence of podoconiosis, there are few control and prevention initiatives exist in Ethiopia. These initiatives are limited in certain parts of Ethiopia. In Wolayta zone, the Mossy Foot Treatment and Prevention Association (MFTPA) has been documented as effective continuing podoconiosis community program model since 1998 as compared to the WHO Innovative Care for Chronic Conditions (ICCC) Framework\textsuperscript{9}. The MFTPA program involves prevention (distribution of shoes to children, adult shoemaking), treatment (shoe wearing education integrated into clinics/hygiene), and rehabilitation (microcredit, training) activities at the community-level across one zone. In June 2010, the first podoconiosis program in Northern Ethiopia was started in Debre Markos, East Gojam Zone in an effort to take the experiences of MFTPA and develop a program specific to the context of Northern Ethiopia.
program in Debre Markos aims to address podoconiosis prevention, awareness, and care and support activities\textsuperscript{10}.

Ethiopia also developed a guideline for lymphatic filariasis and podoconiosis morbidity management and disability prevention that contribute its part in the control and elimination of podoconiosis. The guideline is helpful for general medical practitioners, health officers, nurses and other mid-level health practitioners in their efforts to reduce morbidity and disability of podoconiosis\textsuperscript{10}.

Despite the above mentioned efforts made by government of Ethiopia, there was no scientific data that show level of knowledge, attitude and practices of health professionals towards podoconiosis in the study area. Therefore the aim of this study was to assess the knowledge, attitude, practices and associated factors of health professionals towards podoconiosis in Gamo zone, Southern Ethiopia.

2. Methods And Materials

2.1. Study setting and period

The study was conducted in Gamo zone, Southern Ethiopia from September 1 to December 30, 2019. Gamo zone is one of the zones in the Southern Nations, Nationalities, and Peoples' Region of Ethiopia. According to the 2007 Ethiopian central statistics agency Census, the zone had a total population of 1,341,901 of whom 668,230 were men and 673,671 were women. Majority of the population 1,292,653 (96.33\%) live in rural area.

The current profile indicated that there are 5 hospitals, 33 private clinics and 53 health centers in Gamo zone. There are a total of 3767 and 587 health professionals and health extension workers in the zone, respectively.

2.2 Study design

Facility based cross-sectional design was employed

2.3. Study Population:

All health professionals in randomly selected districts were our study population.

2.4. Eligibility criteria

2.4.1. Inclusion criteria:

All health professionals working currently in public health facilities in randomly selected districts were included in the study.

2.4.2. Exclusion criteria
Anesthesia and environmental health professionals.

Eligible health professionals not willing to participate and absent during study period.

2.5. Sample size determination

Sample size was determined by using single population proportion formula with the assumption presented below:

\[
N = \frac{z_{\alpha/2}^2 \times P(1-P)}{d^2}
\]

Where,

\(N\) = initial sample size

\(z_{\alpha/2}\) = significance level at 95% confidence interval = 1.96

\(P\) = 50% was to get the highest sample size.

Degree of margin = 5%

\[
N = \frac{1.96^2 \times 0.5 \times 0.5}{0.05^2} = \frac{3.8416 \times 0.25}{0.0025} = 384
\]

Since the total population was less than 10,000, we used finite population correction formula

As \( n = n_0 \times \frac{N}{N-1} \), \( 384 \times 3767 = 349 \), the final estimated sample size was 349.

2.6. Sampling procedure

Boreda, Kamba and Geresse districts were randomly selected from total of thirteen in the zone. Then all health professionals in the selected districts were approached for the survey. All eligible study subjects were self-administered the structured questionnaire and continue until the required sample size fulfilled.

2.7. Study variables

2.7.1. Dependent variables

Knowledge (good/poor)

Attitude (favorable or unfavorable)
Practice (ever treated podoconiosis yes or not)

1.1.1. Independent variables

Socio-demographic variables: age, sex, marital status, type of health facility, level of health facility, type of profession, service year of health professionals (HP), availability of drugs and supplies/treatment guidelines on podoconiosis, training on podoconiosis.

2.8. Operational definitions

Knowledge was assessed in terms of what a person knows about podoconiosis and whether this knowledge was true or false. A person had good knowledge if he/she scored 75% or more of the knowledge question and poor knowledge if he/she answered less than 75% of the knowledge questions.

Attitude questions was measured by using likart scale as strongly agree, agree, neutral, disagree and strongly disagree. Disagree and neutral response were categorized as disagree. Those individuals who agree 75% or more of attitude questions was categorized as favorable attitude and participants who agree below the 75% as categorized in to unfavorable attitude.

Practice: those health professionals who ever treated podoconiosis (yes or no).

2.9. Data collection

Data were collected by using self-administered structured questionnaire. The questionnaire covered four sections, socio-demographic characteristics, knowledge about podoconiosis cause, prevention and treatment, attitude towards podoconiosis patients and experiences in treating podoconiosis patients. Ten data collectors and three supervisors were recruited for data collection.

2.10. Data quality control

To maintain data quality, data collection tool was used. The questionnaire was prepared in English. Pretested was done on 5% of the total sample size. Four day training was given for the data collectors and the supervisors. Daily supervision was carried out to check the completeness and consistency of the questionnaire.

2.11. Data processing and analysis

Epi info version 7 was used for coding, entering and cleaning the collected data and the data was imported to and analyzed by using SPSS version 20. Bivariate analysis was done to determine the associations between each independent variables and outcome variables. All associated factors with p-value less than 0.25 during bivariate analysis were entered in to multivariable logistic regression model. Odds ratio with 95% confidence intervals was used to see the strength of association between different variables. P-value and 95% confidence interval (CI) for odds ratio (OR) was used in deciding the significance of the associations. Before inclusion of independent factors, multi-collinearity was checked using cutoff points Variance Inflation Factor (VIF) < 10 and normality was checked by Q-Q probability plots. Hosmer-
Lemeshow goodness of fit was also checked for the model at P-value > 0.05. Finally data were presented in text, tables and graphs.

3. Result

3.1. Socio-demographic characteristics of the respondents

Of the total 349 estimated sample, 320 health professionals filled the questionnaire with a response rate of 92%. Majority 202 (63.1%) of the study subjects were in the age group 25 to 34 years old. From the total participants, 205 (64.1%) were males. Regarding professional background, most 162 (50.6%) of the respondents were diploma nurses [Table 1].
Table 1
Socio-demographic characteristics of health professionals in Gamo zone, Southern Ethiopia, 2019.

| Variables          | Alternatives       | Frequency | Percentage |
|--------------------|--------------------|-----------|------------|
| Age                | 25–34              | 202       | 63.1%      |
|                    | 35–44              | 106       | 33.1%      |
|                    | 45 and above       | 12        | 3.8%       |
|                    | Total              | 320       | 100%       |
| Sex                | Female             | 115       | 35.9%      |
|                    | Male               | 205       | 64.1%      |
| Profession         | BSc nurse          | 58        | 18.1%      |
|                    | HO                 | 57        | 17.8%      |
|                    | Diploma nurse      | 162       | 50.6%      |
|                    | Pharmacy           | 9         | 2.8%       |
|                    | Lab technician     | 18        | 5.7%       |

|                    | 6 to 10 years      | 98        | 30.6%      |
|                    | 11 and above years | 51        | 16%        |

*Divorced and widowed

3.2. Knowledge of health professionals towards podoconiosis prevention and control

All (100%) of the respondents had ever heard about podoconiosis. Seventy (21.9%) health professionals responded as podoconiosis is infectious disease. Regarding the cause, 38 (11.9%) and 71 (22.1%) said that the disease is caused by parasite and curse/evil eye, respectively. Forty five percent of participants incorrectly answered about risk factor for podoconiosis. In general, 68 (23.1%) health professionals had poor knowledge towards prevention and control of podoconiosis (Table 2).
Table 2
knowledge of health professionals on podoconiosis prevention and control in Gamo zone, Southern Ethiopia, 2019. (N = 320)

| Variables                                  | Alternatives                        | Frequency (n) | Percentage (%) |
|--------------------------------------------|-------------------------------------|---------------|----------------|
| Podoconiosis is infectious disease         | Yes                                 | 70            | 21.9           |
|                                            | No                                  | 250           | 78.1           |
| Cause of podoconiosis                      | Hereditary disease                  | 57            | 17.8           |
|                                            | Parasitic disease                   | 71            | 22.1           |
|                                            | Curse/evil eye                       | 38            | 11.9           |
|                                            | Soil particle                        | 154           | 48.1           |
| Risk factor for podoconiosis (multiple options) | Not wearing shoes                  | 176           | 55             |
|                                            | Improper foot hygiene               | 188           | 58.8           |
|                                            | Not using bed net                   | 144           | 45             |

|                                            | Upper arm swelling                  | 193           | 60.3           |
|                                            | Scrotal swelling                     | 40            | 12.5           |
|                                            | Breast swelling                      | 71            | 22.2           |
| Prevention measures of podoconiosis (multiple options) | Avoiding stepping on dead animals | 10            | 3.1            |
|                                            | Proper and regular shoe wearing     | 193           | 60.3           |
|                                            | Avoiding prolonged bare foot contact with irritant red clay soil | 200 | 62.5 |
|                                            | Daily foot washing                  | 268           | 83.8           |
|                                            | Covering floors                     | 74            | 23.1           |
|                                            | Use bed net                         | 81            | 25.3           |
| Management of podoconiosis patients (multiple options) | Foot hygiene | 124 | 38.8 |
|                                            | Elevation and exercise              | 192           | 60             |
|                                            | Bandaging                            | 133           | 41.6           |
|                                            | Skin care                            | 153           | 47.8           |
|                                            | Wound care                           | 168           | 52.5           |
|                                            | counseling                           | 198           | 61.9           |
| Knowledge status                           | Poor                                | 74            | 23.1           |
### 3.3. Attitude of health professionals on podoconiosis prevention and control measures

More than half 180/320 (56%) of study subjects had favorable attitude towards podoconiosis patients. Most of health professionals 191/320 (59.7%) disagreed that they had adequate knowledge and skill to give care and treatment for podoconiosis patients. Forty seven (14.7%) believed that they may acquire podoconiosis if treated patients and 32 (10%) of the study participants were neutral to whether they acquire the disease or not (Table 3 and Fig. 1).

| Variables          | Alternatives | Frequency (n) | Percentage (%) |
|--------------------|--------------|---------------|----------------|
| Good               |              | 246           | 76.9           |
Table 3
Attitude of health professionals on podoconiosis prevention and control measures

| Variables                                                                 | Strongly agree (1) | Agree (2)   | Neutral (3)  | Disagree (4) | Strongly disagree (5) |
|---------------------------------------------------------------------------|--------------------|-------------|--------------|--------------|-----------------------|
| I feel I had adequate knowledge and skill to give care and treatment for podoconiosis patients | 1(0.3%)            | 26(8.1%)    | 28(8.8%)     | 191(59.7%)    | 74(23.1%)             |
| I may acquire podoconiosis if I am in contact with podoconiosis patients | 0                  | 47(14.7%)   | 32(10%)      | 182(56.9%)    | 59(18.4%)             |
| I feel podoconiosis patients deserve care and support                     | 146(45.6%)         | 167(52.2%)  | 7(2.2%)      | 0             | 0                     |
| People with podoconiosis should be legally separated from others to protect the public health | 0                  | 3(0.9%)     | 46(14.5%)    | 173(54%)      | 98(30.6%)             |
| I feel comfort if I buy food or items from a shop keeper with podoconiosis | 77(24.1%)          | 142(44.4%)  | 57(17.8%)    | 42(13.1%)     | 2(0.6%)               |

3.4. Practice of health professionals in the treatment of podoconiosis patients

With respect to practice, very few, 37/320 (11.6%) health professionals had ever treated podoconiosis patients. Majority, 283/320 (88.4%) did not ever treat podoconiosis patients due to different reasons, 150/283 (53%) no LMMDP, 100/283 (35.3%) no training given and 33/283 (11.8%), no case. Most,
311/320 (97.2%) of health professionals had no LMMDP guideline for managing patients in their health facilities (Table 4).

Table 4
practice of study subjects towards management of podoconiosis cases in Gamo zone, SNNPR, Ethiopia, 2019

| Variables                                               | Category       | Frequency | Percent |
|---------------------------------------------------------|----------------|-----------|---------|
| Ever treated podoconiosis patients                      | Yes            | 37        | 11.6%   |
|                                                         | No             | 283       | 88.4%   |
|                                                         | Total          | 320       | 100%    |

|                                                         | No case        | 33        | 11.7%   |
| Availability MMDP guideline                             | Yes            | 9         | 2.8%    |
|                                                         | No             | 311       | 97.2%   |

**3.5. Factors associated with knowledge, attitude and practice of health professionals towards podoconiosis**

After adjusting other variables profession, address of health facility, service year and attitude of participants became significantly associated with knowledge towards podoconiosis. Health professionals whose profession was BSc nurse, health officers (HO) and diploma nurse had significantly higher chance to have good knowledge (AOR = 11.44, 95%CI: 3.79, 34.547), (AOR = 24.977, 95%CI: 6.412, 97.25) and (AOR = 3.522, 95%CI: 1.65, 7.5), respectively (Table 5).

Table 6
Multivariable logistic analysis for attitude score of study subject in Gamo zone, SNNPR, Ethiopia, 2019.

In multivariable logistic regression analysis age 45 years old and above was significantly higher chance to ever treat podoconiosis patients than age between 25–34 years old (AOR = 17.345; 95%CI: 4.62, 65.119). Health professionals who trained on LMMDP were 7.4 times more likely to ever treat podoconiosis patient than not trained individuals (AOR = 7.385; 95%CI: 2.5, 21.797) (Table 7).

4. Discussion

The current study showed that near to one fourth of health professionals had poor knowledge towards prevention and control of podoconiosis. About 22% of the study subjects responded as podoconiosis is infectious disease. Regarding the cause, 48%, 11.9% and 22.1% said that the disease is caused by soil particles, parasite and curse/evil eye, respectively. Fifty five percent of participants correctly answered that not wearing shoes is risk factor for podoconiosis. This is finding is almost similar with study done in Rwanda in which about 61% of study subjects knew that walking barefoot was a risk factor for acquiring podoconiosis \(^{11}\). The possible explanation for this result may be similar interventions taken by the two countries.
The present study showed that more than three fourth of the subjects had good knowledge towards the disease. On the contrary, in Rwanda about 60% of health professionals had good knowledge\textsuperscript{11}. This difference might be due to efforts done by ministry of health Ethiopia on prevention and control measures like training health workers on LMMDP increased the knowledge of the study subjects.

According to the present study, knowledge score was significantly associated with profession, service year and attitude of the study participants. BSc nurses, health officers and diploma nurses had 11, 25 and 4 times more likely to have good knowledge than other professionals like midwife, laboratory and pharmacy technicians, respectively. The possible explanation would be due to the fact that other health professionals had low exposure to disease management and training in Ethiopia.

The present study found that 56% of the study subjects had favorable attitude towards podoconiosis patients. This finding was not consistent with study done in Rwanda in that 86% of respondents expressed positive attitudes towards podoconiosis\textsuperscript{11}. Our finding is also not in line with study conducted in Wolayta zone in which 72.4% of health professionals had favorable attitude towards providing care for podoconiosis patients\textsuperscript{12}. This difference might be due to on job trainings and other interventions given to health professionals regarding podoconiosis in the comparative areas.

In the current study, only eight percent felt that they had adequate knowledge and skill to give care and treatment for podoconiosis patients. Forty seven (14.7%) of the study subjects believed they may acquire podoconiosis if they are in contact with podoconiosis patients. The possible reason might be the study subjects had poor awareness towards podoconiosis transmission.

In this study, only knowledge of the participants was significantly associated with attitude towards podoconiosis patients. Those health professionals who had good knowledge were 2.4 times more likely to have favorable attitude than poor knowledge. This finding agrees with study done by Bereket Yakob in 2007.\textsuperscript{12} This might be explained by attitude of HPs could be improved by improving knowledge.

Regarding practice of health professionals towards management of cases of podoconiosis, very few 37/320 (11.6%) health professionals ever treated podoconiosis patients. The current study showed lower practice when compared to other previously conducted studies.\textsuperscript{12} The low practice might be related with inadequate provision of medical supplies and in-service trainings.

Our study revealed that training on LMMDP and age category was significantly associated with ever treating podoconiosis patients. Health professionals who trained on LMMDP were 7.4 times more likely to treat cases than others. On the other hand, age group 45 years old above individuals were 17 times higher chance of to be treated podoconiosis patients when compared to age group 25–34 years old. This might be possibly because of the older age groups had more experience in treating cases and exposure to managing cases.

This study has the following limitations: we did not include health professionals working in private clinics. We are also unable to include physicians, anesthesia and environmental health workers.
5. Conclusion And Recommendations

Despite, high percent of good knowledge and favorable attitude of health professionals towards podoconiosis, practice of study subjects on treating cases was very low. In this study knowledge score was significantly associated with profession, service year and attitude of the study participants. Only knowledge status was significantly related with attitude of participants. Those individuals who had good knowledge have 2.4 times more likely to have favorable attitude than those who had poor knowledge score. Health professionals who trained on LMMDP and age category equals or above 45 years old were significantly associated with practices of health professionals. In-service trainings will be given for health professionals to improve practice. In podoconiosis endemic districts hygiene supplies and other referencing materials should be made available for podoconiosis case management.

Declarations

ACKNOWLEDGEMENTS

We would like to express our deepest gratitude and appreciation to lord of wisdom, God.
We are grateful to Arba Minch University Collaborative Research Training Center for Neglected Tropical Diseases for their full sponsorship of this research work.

We are also grateful to all data collectors and supervisors, who tried their best and committed themselves to data collection.

**Authors Contribution**

CC conceptualized the study and methodology, collected all data, performed data analysis, was responsible for all aspects of the project administration and funding acquisition, also wrote the original draft and the subsequent works. MA and ZZ contributed to the conceptualization and methodology, data collection, reviewed and edited the manuscript. AT and EG contributed to methodology, supervised, reviewed and edited the manuscript. All authors read and approved the final manuscript.

**Funding**

This study was funded by the Arba Minch University, College of Medicine and Health Sciences.

**Availability of data and materials**

The datasets used and/or analyzed during the current study are available from the corresponding author on reasonable request.

**Ethics approval and consent to participate**

Ethical approval for this study was obtained from institute research board (IRB), Medicine and Health Science College, Arba Minch University. Support letter was obtained from Gamo zone health department and the district health offices to facilitate the data collection. Informed verbal consent was obtained from each study participants before proceeding to data collection.

**Conflict of interest**

All authors declare that there are no conflicts of interest in relation to this work.
