Algebraic decoding of negacyclic codes over $\mathbb{Z}_4$

Eimear Byrne · Marcus Greferath · Jaume Pernas · Jens Zumbrägel

Abstract In this article we investigate Berlekamp’s negacyclic codes and discover that these codes, when considered over the integers modulo 4, do not suffer any of the restrictions on the minimum distance observed in Berlekamp’s original papers: our codes have minimum Lee distance at least $2t + 1$, where the generator polynomial of the code has roots $\alpha, \alpha^3, \ldots, \alpha^{2t-1}$ for a primitive $2n$th root of unity in a Galois extension of $\mathbb{Z}_4$; no restriction on $t$ is imposed. We present an algebraic decoding algorithm for this class of codes that corrects any error pattern of Lee weight $\leq t$. Our treatment uses Gröbner bases, the decoding complexity is quadratic in $t$.

Keywords Negacyclic code · Integers modulo 4 · Lee metric · Galois ring · Decoding · Gröbner bases · Key equation · Solution by approximations · Module of solutions

1 Introduction

In his seminal papers [2,3], Berlekamp introduced negacyclic codes over odd prime fields \( \text{GF}(p) \), and designed a decoding algorithm that corrects up to \( t \leq \frac{p-1}{2} \) Lee errors. The main idea in Berlekamp’s contribution is to represent error patterns of weight \( w \) solely by error locator polynomials of degree \( w \), where the error values are encoded essentially in the multiplicity of the respective error locations. Berlekamp’s error locator polynomial satisfies some type of key equation that is solved during the decoding procedure. Its solution ultimately depends on the multiplicative invertibility of all odd integers \( i \leq 2t-1 \) in a field extension of \( \text{GF}(p) \) where \( t \) is the maximum Lee weight of all correctable error patterns. This finally requires \( t < \frac{p+1}{2} \), which is the reason why this idea yields only a very small class of useful codes.

The project underlying this article revisits Berlekamp’s work and starts with the observation that almost all of the algebra used in the quoted papers is still valid in a Galois ring, i.e., a Galois extension of the integers modulo \( p^s \) where \( s \) might be greater than 1. The divisibility condition mentioned above causes problems if and only if \( p \) is odd, and this brought us to the idea to study codes over \( \mathbb{Z}_4 \).

The paper at hand considers the simplest (non-trivial) case, namely the case where \( s = 2 \), which means we consider negacyclic codes over \( \mathbb{Z}_4 \) under the Lee metric. We will show that a negacyclic code is indeed of minimum Lee distance at least \( 2t+1 \) if its generator polynomial has roots \( \alpha, \alpha^3, \ldots, \alpha^{2t-1} \) for a primitive 2\( n \)th root of unity \( \alpha \) in a Galois extension of \( \mathbb{Z}_4 \). No restriction on \( t \) will be imposed. We present an algebraic decoding algorithm for this class of codes that corrects any error pattern of Lee weight \( \leq t \). In fact, if the minimum Lee distance is at least \( 2r+1 \) (where \( r \geq t \)), we derive a key equation which has a unique solution in all error patterns of Lee weight \( r \). Then we find the unique solution using Gröbner bases, provided at most \( t \) errors have occurred.

Our presentation is organized as follows: In Sect. 2 we review some basic facts about Galois rings. Then in Sect. 3 we outline the theory of quaternary negacyclic codes and prove a lower bound on their minimum Lee distance. The discussion of algebraic decoding starts with Sect. 4, where a key equation for the error locator polynomial is established. To solve this key equation, an efficient algorithm requiring \( O(t^2) \) ring operations is developed using Gröbner bases in Sect. 6, and for this purpose some preparative results are provided in Sect. 5. Finally, in Sect. 7 the complete decoding algorithm is presented and an elaborated example is given.

2 Preliminaries

Throughout this paper, let \( R \) denote the Galois ring \( \text{GR}(4, m) \) of characteristic 4, order \( 4^m \), and residue field \( K = \text{GF}(2^m) \). We let \( \mu : R \longrightarrow K, a \mapsto a + 2R \) be the canonical map from \( R \) onto \( K \).

The structure of \( R \) is well understood (cf. [8]). Its multiplicative group \( R^\times \) has order \( 2^m(2^m-1) \) and contains a unique cyclic subgroup of order \( 2^m-1 \). This group, in union with zero, forms the so-called Teichmüller set of \( R \), which we denote by \( \mathcal{T} \). The set \( \mathcal{T} \) forms a complete set of coset representatives of \( 2R \) in \( R \) and so the image of \( \mathcal{T} \) under \( \mu \) is the residue field \( K \). Each element \( a \in R \) can be expressed in the canonical form \( a := a_0 + 2a_1 \) for suitable \( a_0, a_1 \in \mathcal{T} \). The automorphism group of \( R \) is cyclic of order \( m \) and with respect to the above canonical form is generated by the map
Now follows from the above isometry observation.

3 Negacyclic codes over $\mathbb{Z}_4$

The following is a BCH-like description of negacyclic codes over $\mathbb{Z}_4$, and can be read as the obvious extension of Berlekamp’s work in [2,3]. We outline the theory for the convenience of the reader, see [9] for further details.

**Definition 1** Let $n$ be a positive integer. A negacyclic code of length $n$ over $\mathbb{Z}_4$ is an ideal in the ring $\mathbb{Z}_4[x]/(x^n + 1)$.

We will work with roots of a negacyclic code, i.e., elements $\alpha \in R$ satisfying $\alpha^n = -1$. Note that roots in $R$ exist only if $n$ is odd: if $n = 2\ell$ was even and $\alpha^{2\ell} = -1$, then $\alpha^\ell$ was an element of order 4 in $R$, which is impossible.

Henceforth we will assume that $n$ is odd. Then there is a primitive 2$\ell$th root of unity $\alpha$ in $R$ such that $\alpha^n = -1$, i.e., $\alpha = -\beta$, where $\beta$ is a primitive $n$th root of unity in $R$.

Any $\mathbb{Z}_4$-negacyclic code is a principal ideal in $\mathbb{Z}_4[x]/(x^n + 1)$, in fact it is generated by a polynomial of the form $a(b + 2) \in \mathbb{Z}_4[x]$ where $x^n + 1 = abc$ and $a, b, c$ are pairwise coprime polynomials, in which case the code has size $4^6c^2b^2$ where $\delta f$ denotes the degree of the polynomial $f$ (cf. [9, Th. 2.7]). There is a natural correspondence between cyclic and negacyclic codes over $\mathbb{Z}_4$. This is given by the map

$$\lambda : \mathbb{Z}_4[x]/(x^n - 1) \longrightarrow \mathbb{Z}_4[x]/(x^n + 1), \quad a(x) \mapsto a(-x).$$

Clearly, $\lambda$ is ring isomorphism, from which it follows that any ideal $C$ in $\mathbb{Z}_4[x]/(x^n - 1)$ is mapped to an ideal $\lambda(C)$ of $\mathbb{Z}_4[x]/(x^n + 1)$. Moreover, $\lambda$ is an isometry with respect to the Lee distance, since for every $c = c_0 + c_1x + \cdots + c_{n-1}x^{n-1} \in \mathbb{Z}_4[x]/(x^n - 1)$, we have $\lambda(c) = c_0 - c_1x \pm \cdots + c_{n-1}x^{n-1}$ which is obviously of the same Lee weight as $c$.

**Theorem 1** Let $C$ be a negacyclic code over $\mathbb{Z}_4$ of odd length $n$ whose generator polynomial $g$ has the roots $\alpha, \alpha^3, \ldots, \alpha^{2t-1}$ for some primitive $2t$th root of unity $\alpha \in R$ such that $\alpha^n = -1$. Then $C$ has minimum Lee distance $d_{\text{Lee}}$ at least $2t + 1$.

**Proof** Let $D$ be the pre-image of $C$ under $\lambda$. Then $D$ is a cyclic code of length $n$, with generator polynomial $f$ satisfying $\lambda(f) = g \in \mathbb{Z}_4[x]$. Then $f$ has the roots $\beta, \beta^3, \ldots, \beta^{2t-1}$ where $\beta = -\alpha$ is a primitive $n$th root of unity in $R$. Now $f \in \mathbb{Z}_4[x]$ is fixed by the automorphism $\pi$, so that $0 = \pi(f(\theta)) = f(\pi(\theta))$ for any root $\theta$ of $f$ in $R$. Since $\beta$ is contained in the Teichmüller set of $R$, $f$ also has the roots $\pi^i(\beta^i) = \beta^{2j}$ for $i \in \{1, 3, \ldots, 2t - 1\}$. Therefore, $f$ has the $2t$ consecutive roots $\beta, \beta^2, \ldots, \beta^{2t}$. A generalization of the well-known BCH bound (see for example [4, Th. IV.1]) shows that $D$ has minimum Hamming distance at least $2t + 1$. This gives a trivial lower bound on the minimum Lee distance of $D$. The claim now follows from the above isometry observation.

**Remark 1** The lower bound on the Lee distance of negacyclic codes given in Theorem 1 is in general not sharp. Indeed there are codes $C$ with $d_{\text{Lee}} > 2t + 1$, as Table 1 shows. If the
actual Lee distance is at least 2r + 1 with r > t we will see in the next section that the key equation carries sufficient information to determine all error pattern of Lee weight at most r, thus being able to correct up to r errors. We will then present a concrete decoding algorithm for error patterns up to Lee weight t.

4 The key equation

Let C be a negacyclic code with roots $\alpha, \alpha^3, \ldots, \alpha^{2t-1}$ and minimum Lee distance $d_{Lee} \geq 2r + 1$. Let $v \in \mathbb{Z}_4[z]$ be a received word satisfying $d(v, C) \leq r$. We will design a decoder to retrieve the unique error polynomial $e$ satisfying $e = v - c$ for some codeword $c$, where $e$ has Lee weight at most r. Most of what follows will be reminiscent of the according steps in Berlekamp’s papers [2,3]. We will amend the methods from those sources to the situation at hand.

Let $w$ denote the Lee weight. We define the error locator polynomial

$$\sigma = \prod_{i=0}^{n-1} (1 - X_i z)^{w(e_i)} \in R[z], \quad (1)$$

where $X_i = 0$ if $e_i = 0$, $X_i = \alpha^i$ if $e_i \in \{1, 2\}$, and $X_i = -\alpha^i = \alpha^{i+n}$ if $e_i = 3$. For each positive integer $k$, we let $s_k$ denote the sum of the $k$th powers of the reciprocals of the roots of $\sigma$, including repeated roots, i.e.,

$$s_k = \sum_{j=0}^{n-1} w(e_j)X_j^k, \quad k \geq 1.$$

We note that $w(e_j)X_j^k = e_j\alpha^{jk}$ holds for all odd $k$. Hence, for each $k \in \{1, 3, \ldots, 2t-1\}$, the $k$th syndrome $s_k = e(\alpha^k) = v(\alpha^k)$ is known to the decoder. Let $s$ denote the power series $\sum_{k=1}^{\infty} s_k z^k \in R(z)$. We have

$$\sigma'(z) = -\sum_{j=0}^{n-1} w(e_j)X_j \prod_{i \neq j} (1 - X_i z)^{w(e_i)} (1 - X_j z)^{w(e_j)-1}.$$
and thus
\[
z\sigma'(z) = -z \sum_{j=0}^{n-1} \prod_{i=0}^{n-1} \frac{(1 - X_i z) w(e_i) w(e_j) X_j}{1 - X_j z} = -\sigma(z) \sum_{j=0}^{n-1} w(e_j) \sum_{k=1}^{\infty} (X_j z)^k
\]
\[
= -\sigma(z) \sum_{k=1}^{\infty} \left( \sum_{j=0}^{n-1} w(e_j) X_j^k \right) z^k = -\sigma(z) \sum_{k=1}^{\infty} s_k z^k = -\sigma(z)s(z).
\]

Therefore
\[
\sigma s + z\sigma' = 0, \quad (2)
\]
where the coefficients \(s_1, s_3, \ldots, s_{2t-1}\) are known to the decoder. For any power series \(P(z) = \sum_{k=0}^{\infty} P_k z^k \in R(z)\) we denote the even part and the odd part by \(P_e = \sum_{j=0}^{\infty} P_{2j} z^{2j}\) and \(P_o = \sum_{j=0}^{\infty} P_{2j+1} z^{2j+1}\), respectively. Then the even part and the odd part of Eq. 2 read
\[
s_e \sigma_e + s_o \sigma_o + z(\sigma_e)' = 0, \quad (3)
s_e \sigma_o + s_o \sigma_e + z(\sigma_o)' = 0. \quad (4)
\]

Subtracting \(\sigma_e\) times Eq. 4 from \(\sigma_o\) times Eq. 3 results in the equation
\[
s_o (\sigma_o^2 - \sigma_e^2) + z((\sigma_e)' \sigma_o - (\sigma_o)' \sigma_e) = 0, \quad (5)
\]
which involves only the odd part of \(s\), the latter being known modulo \(z^{2r+1}\). Now let \(u = \frac{\sigma_o}{\sigma_e} \in R(z)\) and rewrite Eq. 5 to obtain
\[
s_o (u^2 - 1) = zu', \quad (6)
\]
from which we can recursively compute the coefficients \(u_1, u_3, u_5, \ldots, u_{2t-1}\) via the equations
\[
u_1 = -s_1
\]
\[
u_3 = \frac{-s_3 + u_1^2 s_1}{3}
\]
\[
u_5 = \frac{-s_5 + u_1^2 s_3 + 2u_1 u_3 s_1}{5}
\]
\[
\vdots
\]
The reader should notice that this is the point where Berlekamp’s original approach can continue only by imposing a severe restriction on \(t\). In our situation however all the above denominators are invertible in \(R\).

Clearly, \(u\) is an odd function and so we may define the power series \(T\) by
\[
T(z^2) = (1 + zu(z))^{-1} - 1. \quad (7)
\]
Moreover, the coefficients \(T_1, \ldots, T_t\) are all known to the decoder. Next, we define the polynomials \(\varphi, \omega \in R[z]\) by the equations
\[
\omega(z^2) = \sigma_e(z), \quad \text{and} \quad \varphi(z^2) = \sigma_e(z) + z\sigma_o(z). \quad (8)
\]
Noting that \(1 + T(z^2) = -\frac{\sigma_e}{\sigma_e + z\sigma_o}\) we finally arrive at a key equation:
\[(1 + T) \varphi \equiv \omega \mod z^{t+1}, \quad (9)\]

which is the main task of the decoder to solve.

Knowledge of \( \varphi \) and \( \omega \) is sufficient to recover the error locations along with their multiplicities. Using Eq. 8 we may obtain \( \sigma \). The decoder could run through the \( 2n \) roots of unity \( 1, \alpha, \ldots, \alpha^{2n-1} \) and determine the error polynomial \( e \) by

\[
e_j = \begin{cases} 
0 & \text{if } \sigma(\alpha^{-j}) \neq 0 \text{ and } \sigma(\alpha^{-j+n}) \neq 0 \\
1 & \text{if } \sigma(\alpha^{-j}) = 0 \text{ and } \sigma(\alpha^{-j+n}) \neq 0 \\
2 & \text{if } \sigma(\alpha^{-j}) = 0 \text{ and } \sigma(\alpha^{-j+n}) = 0 \\
3 & \text{if } \sigma(\alpha^{-j}) \neq 0 \text{ and } \sigma(\alpha^{-j+n}) = 0 
\end{cases}
\]

Now we will show that the key equation carries sufficient information to determine any error pattern of Lee weight at most \( t \). Let \( B(0, r) \) denote the ball in \( \mathbb{Z}_4^n \) centered in 0 with radius \( r \), and let \( \alpha : B(0, r) \to R[z] \) be the function \( e \mapsto \sigma \), mapping an error pattern to its error locator polynomial (see Eq. 1), which is injective. Then we consider the function

\[
f : \alpha(B(0, r)) \to R^t, \quad \sigma \mapsto (T_1, \ldots, T_t),
\]

where the coefficients \( T_1, \ldots, T_t \) of the power series \( T \) are obtained as outlined above (see Eqs. 6 and 7).

**Lemma 1** The map \( f : \sigma \mapsto (T_1, \ldots, T_t) \) is injective on \( \alpha(B(0, r)) \).

**Proof** Consider the syndrome map \( \mathbb{Z}_4[z]/(z^n + 1) \to R^t \) given by \( v \mapsto (s_1, s_3, \ldots, s_{2t-1}) \), with \( s_k = v(\alpha^k) \). Its kernel equals the code \( C \) of Lee distance at least \( 2r + 1 \), hence the map is injective on \( B(0, r) \). Now we observe that the mappings \( (s_1, \ldots, s_{2t-1}) \mapsto (u_1, \ldots, u_{2t-1}) \mapsto (T_1, \ldots, T_t) \) of Eqs. 6 and 7 are bijective. \( \square \)

**Proposition 1** Let \( S := R[z]/(z^{t+1}) \). For any \( T = \sum_{i=1}^t T_i z_i \in S \) there is at most one error locator polynomial \( \sigma \in \alpha(B(0, r)) \) such that the corresponding key equation \( (1 + T) \varphi = \omega \) in \( S \) is satisfied, where \( \varphi(z^2) = \sigma(z) \) and \( \varphi(\omega z) = \sigma_\omega(z) = z \sigma_\omega(z) \).

**Proof** Suppose that \( \sigma \in \alpha(B(0, r)) \) satisfies \( (1 + T) \varphi = \omega \). Now \( S \) is a local ring with maximal ideal \( (z) \), and as \( \sigma(0) = 1 \) we have \( \varphi(0) = \omega(0) = 1 \), so that \( \varphi \) and \( \omega \) are units in \( S \). This implies \( 1 + T = \omega \varphi^{-1} \), in particular, \( T \) is uniquely determined by the key equation. As also \( f(\sigma) \) satisfies the key equation by construction we have thus \( T = f(\sigma) \). Since \( f \) is injective, it must hold \( \sigma = f^{-1}(T) \), and \( \sigma \) is hence uniquely determined. \( \square \)

In the view of Proposition 1 it remains an open problem to find the unique solution of the key equation efficiently. In the following we assume that \( e \) has Lee weight at most \( t \), and we present an efficient decoding method for this case.

For the classical finite field case, there is a unique pair of coprime polynomials \( [a, b] \in \text{GF}(p^m)[z]^2 \) satisfying the key equation, Eq. 9, along with the constraints:

\[
a(0) = b(0) = 1, \quad \delta a \leq \frac{t+1}{2}, \quad \delta b \leq \frac{t}{2}.
\]

For the Galois ring case, it is apparent that the required solution pair \( [\varphi, \omega] \) satisfies the constraints of Eq. 10. Although \( \varphi \) and \( \omega \) are not necessarily coprime in \( R[z] \), we will show in the next section that \( 2 \in R[z] \varphi + R[z] \omega \). Now over the ring \( R \), a solution \( [a, b] \) of the key equation satisfying \( 2 \in R[z]a + R[z]b \) and the constraints of Eq. 10 will still not be unique in general, but the modulo 2 solution \( [\mu a, \mu b] \in K[z] \) is unique, which will be sufficient for the decoding problem.
5 The ideal generated by \( \varphi \) and \( \omega \)

We will show that 2 can be expressed as an \( R[z] \)-linear combination of \( \varphi \) and \( \omega \). First we note some useful observations.

Let \( S \) be a commutative ring with identity 1. For \( f, g \in S \) we use the notation \( (f, g) := Sf + Sg \) to denote the ideal generated by \( f \) and \( g \) in \( S \).

**Lemma 2** Let \( f, g, h \in S \). Then

(a) \( (f, g) = (f, hf + g) \),
(b) \( (h, g) = S \) implies \( (f, g) = (hf, g) \).

**Proof** We will only prove the inclusion \( (f, g) \subseteq (hf, g) \) in (b). Since \( (h, g) = S \) there are \( a, b \in S \) such that \( ah + bg = 1 \), and consequently \( ahf + bgf = f \). Now, for all \( r, s \in S \) we have \( rf + sg = r(ahf + bgf) + sg = (ra)hf + (rbf + s)g \).

**Lemma 3** Let \( a, b, u, v \in S \) and let \( f = a + b, g = u + v \). Suppose that

\[
2b = 0, \ (f, g) = S, \ \text{and} \ (g, u) = S.
\]

Then \( (fg, au + bv) = (f, a) \).

**Proof** First we observe \( au + bv = au - bv = ag - fv \). Next, using Lemma 2, we obtain \( (g, ag - fv) = (g, f v) = (g, v) = (g, u) = S \). Hence, again using Lemma 2, \( (fg, au + bv) = (fg, ag - fv) = (fg, ag - f v) = (f, ag) = (f, a) \).

We now specialize to the case that \( S = R[z] \) where \( R \) is a Galois ring with residual field \( K \). The following is well-known.

**Lemma 4** Let \( f, g \) be polynomials in \( R[z] \), then \( (f, g) = R[z] \) if and only if \( (\mu f, \mu g) = K[z] \).

Consider the polynomial

\[
\Sigma(z) := \prod_{i=1}^{r} (1 - Y_i z)^{a_i} \in R[z],
\]

for some \( a_i \in \{1, 2\} \) and \( Y_i \in R \) such that the \( \mu Y_i \in K^\times \) are pairwise distinct. We further let

\[
\tau = \prod_{i=1}^{s} (1 - Y_i z)^{2} \quad \text{and} \quad \varepsilon = \prod_{i=s+1}^{r} (1 - Y_i z)
\]

be the square and non-square part of \( \Sigma \) (under a suitable re-ordering of the \( Y_i \) if necessary).

As before, we denote the even and the odd part of a polynomial \( f \in R[z] \) by \( f_e \) and \( f_o \), respectively.

**Lemma 5** Given the above notation, there holds \( 2\tau_o = 0, (\tau, \varepsilon) = R[z], \) and \( (\varepsilon, \varepsilon_o) = R[z] \).

**Proof** Since \( \tau \) is a square, we have \( \mu \tau = \mu \tau_e \). Thus \( \mu \tau_o = 0 \) and hence \( 2\tau_o = 0 \). Since \( \mu \tau \) and \( \mu \varepsilon \) have no common factors, we have \( (\mu \tau, \mu \varepsilon) = K[z] \), and so, by Lemma 4, we have \( (\tau, \varepsilon) = R[z] \).

To show \( (\varepsilon, \varepsilon_o) = R[z] \) we simply show that \( \mu \varepsilon_e \) and \( \mu \varepsilon_o \) are coprime. First we note \( \mu \varepsilon_e(0) = \mu \varepsilon(0) = 1 \), and hence \( z \) is not a common factor of \( \mu \varepsilon_o \) and \( \mu \varepsilon_e \). Suppose now that
a (proper) common factor of $\mu e$ and $\mu e_o$ exists. Since both $\mu e$ and $\mu e_o/z$ are squares the fact that they have a common factor means they have a common factor that is also a square, contradicting the fact that $\mu e$ is square-free. Thus $\mu e$ and $\mu e_o$ are coprime, and hence, by Lemma 4, $(\varepsilon, e) = (e, e_o) = R[z]$. \hfill \Box

**Corollary 1** $(\Sigma, \Sigma_e) = (\tau, \tau_e)$.

**Proof** We observe that $\Sigma_e = \tau_e e + \tau_o e_o$. Combining Lemma 3 and Lemma 5 we obtain $(\Sigma, \Sigma_e) = (\tau e, \tau_e e + \tau_o e_o) = (\tau, \tau_e)$. \hfill \Box

**Lemma 6** Let $f, g \in R[z]$ be squares. Then $(fg)_e = fg_e$.

**Proof** We have $(fg)_e = fge + f_0g_0$. Since $f$ and $g$ are squares, as in the proof of Lemma 5, it follows that $2f_o = 2g_0 = 0$, and hence $f_0g_0 = 0$. \hfill \Box

**Corollary 2** $\tau = \prod_{i=1}^s (1 + Y_i Y_j^{-1})^2$.

With these preparations we can prove:

**Proposition 2** $2 \in (\Sigma_e, \Sigma_o)$.

**Proof** Observe first that $(\Sigma_e, \Sigma_o) = (\Sigma, \Sigma_e)$ and $(\tau, \tau_e) = (\tau, \tau_o)$. Then by Corollary 1 it suffices to show that $2 \in (\tau, \tau_o)$. Since $2\tau_o = 0$ we may write $\tau_o = 2\rho$ for some regular polynomial $\rho \in R[z]$.

We show that $(\mu \tau, \mu \rho) = K[z]$. Clearly, the polynomial $\mu \tau$ fully splits into linear factors over $K$; its roots are $\mu Y_j^{-1}, j = 1, \ldots, s$. On the other hand we show that for all $j$ we have $\mu \rho(\mu Y_j^{-1}) \neq 0$. Using Corollary 2 we find that

$$\tau_e(Y_j^{-1}) = 2 \prod_{i=1, i \neq j}^s \left(1 + (Y_i Y_j^{-1})^2\right) \neq 0,$$

since $\mu (1 + Y_i Y_j^{-1}) \neq 0$ for $i \neq j$. Hence, $\tau_o(Y_j^{-1}) = \tau(Y_j^{-1}) - \tau_e(Y_j^{-1}) = -\tau_e(Y_j^{-1}) \neq 0$, and this implies $\mu \rho(\mu Y_j^{-1}) \neq 0$. This establishes $(\mu \tau, \mu \rho) = K[z]$.

Now by Lemma 4 it follows $(\tau, \rho) = R[z]$, i.e., there are $a, b \in R[z]$ such that $a\tau + b\rho = 1$. Therefore we have $2 = 2a\tau + b2\rho = 2a\tau + b\tau_o \in (\tau, \tau_o)$ as desired. \hfill \Box

**Corollary 3** $2 \in (\varphi, \omega)$.

**Proof** It is clear that $\sigma$ has the same form as $\Sigma$, defined before, and thus $2 \in (\sigma_o, \sigma_e)$. Moreover

$$(\varphi(z^2), \omega(z^2)) = (\sigma_e(z) + z\sigma_o(z), \sigma_e(z)) = (z\sigma_o(z), \sigma_e(z)) = (\sigma_o, \sigma_e),$$

since $(z, \sigma_e) = R[z]$. As $2 \in (\sigma_o, \sigma_e)$ there exist $a, b \in R[z]$ such that $a \varphi(z^2) + b \omega(z^2) = 2$. It follows $a_e \varphi(z^2) + b_e \omega(z^2) = 2$. Therefore we have $u\varphi + v\omega = 2$ with $u, v \in R[z]$ such that $u(z^2) = a_e$ and $v(z^2) = b_e$. \hfill \Box

**Remark 2** Suppose that no ‘double-errors’ occurred, i.e., there is no position $j$ with $e_j = 2$. Then we have $\tau = 1$, and by Corollary 1, we have $(\sigma, \sigma_e) = (\tau, \tau_e) = R[z]$. From this it follows even $(\varphi, \omega) = R[z]$, by a similar argument.
The solution module of the key equation

In this section we investigate the module of solutions to the key equation, Eq. 9, i.e., \( M = \{(a, b) \in R[z]^2 \mid a(1 + T) \equiv b \mod z^{t+1}\} \). First we recall some basic facts on Gröbner basis in \( R[z]^2 \), further details can be found in [1,4,5,7].

**Definition 2** Let \( \ell \) be an integer. We define a term order \( \prec_\ell \) on \( R[z]^2 \) by

(a) \( [z^i, 0] \prec_\ell [z^{j}, 0] \) and \( [0, z^j] \prec_\ell [0, z^i] \) for \( i < j \),

(b) \( [0, z^j] \prec_\ell [z^{i}, 0] \) if and only if \( j \leq i + \ell \).

Let \( \prec \) denote an arbitrary fixed term order. Let \( [a, b] \in R[z]^2 \backslash \{0\} \). Then \( [a, b] \) has a unique expression as a sum of monomials \( [a, b] = \sum_{i \in I} c_i[z^i, 0] + \sum_{j \in J} d_j[0, x^j] \) for some finite index sets \( I, J \) of nonnegative integers, and elements \( c_i, d_j \in R \setminus \{0\} \). The leading term, \( \text{lt}([a, b]) \), of \( [a, b] \) is then identified as the greatest term occurring in the above sum with respect to \( \prec \). The leading coefficient, denoted \( \text{lc}([a, b]) \), is the coefficient attached to \( \text{lt}([a, b]) \) and the leading monomial is \( \text{lm}([a, b]) = \text{lc}([a, b]) \cdot \text{lt}([a, b]) \). For any \( [a, b], [c, d] \in R[z]^2 \) we say that \( [a, b] \preceq [c, d] \) if and only if \( \text{lt}([a, b]) \preceq \text{lt}([c, d]) \). Given a set of non-zero elements of \( R[z]^2 \) there exists in the set a (not necessarily unique) minimal element with respect to the quasi-order \( \preceq \) associated with \( \prec \). We will refer to this element as being minimal with respect to \( \prec \).

We say that \( \text{lt}([a, b]) \) is on the left (resp. right) if \( \text{lt}([a, b]) = [z^j, 0] \) (resp. \( \text{lt}([a, b]) = [0, z^i] \)) for some non-negative integer \( i \). A subset \( \mathcal{B} \) of a submodule \( A \) of \( R[z]^2 \) is called Gröbner basis, if for all \( \alpha \in A \) there exists \( \beta \in \mathcal{B} \) such that \( \text{lm}(\beta) \) divides \( \text{lm}(\alpha) \). The structure of a Gröbner basis in \( R[z]^2 \) is given by the following lemma (cf. [4, Th. V.3]).

**Lemma 7** Let \( A \) be a submodule of \( R[z]^2 \). Suppose that \( A \) has elements with leading terms on the left and elements with leading terms on the right. Then \( A \) has a (not necessarily minimal) Gröbner basis of the form

\[
\begin{align*}
\{(a, b), [c, d], [g, h], [u, v]\}
\end{align*}
\]

with \( \text{lm}(a, b) = [z^j, 0], \text{lm}(c, d) = [2z^j, 0], \text{lm}(g, h) = [0, z^r], \text{lm}(u, v) = [0, 2z^s] \) satisfying \( j \geq s \) and \( r \geq s \). Moreover, the integers \( i, j, r, s \) are uniquely determined.

In [4, Sec. VI] an efficient algorithm to compute a Gröbner basis for a submodule \( M \) of the form \( M = \{(a, b) \in R[z]^2 \mid a U \equiv b \mod z^{r}\} \), for some \( U \in R[z] \), is given, the so-called method of Solution by Approximations. This algorithm generalizes one for the finite field case, derived in [6], which can be viewed as the Gröbner basis equivalent of the Berlekamp–Massey algorithm [3, Alg. 7.4]. The Solution by Approximations method works by computing iteratively a Gröbner basis of each successive solution module \( M^{(k)} = \{(a, b) \in R[z]^2 \mid a U \equiv b \mod z^{k}\} \), finally arriving at a basis of \( M = M^{(r)} \). The algorithm requires no searching at any stage of its implementation and has a complexity of \( O(r^2) \) ring operations.

We describe this method below, which is particularly simple for the case of the Galois ring \( R \) of characteristic 4. The algorithm is basically a method to give the basis \( \mathcal{B}_{k+1} = \{[f_1, g_1], \ldots, [f_4, g_4]\} \) for \( M^{(k+1)} \) knowing the basis \( \mathcal{B}_k = \{[f_1, g_1], \ldots, [f_4, g_4]\} \) for \( M^{(k)} \).

For \( \alpha, \beta \in R \) we say that \( \alpha \) is a multiple of \( \beta \) if there exists \( x \in R \) such that \( \alpha = x \beta \). This holds precisely when \( \beta \in R^\times \) or \( \alpha, \beta \in 2R, \beta \neq 0 \).

**Algorithm 1** (The method of solution by approximations)

Input: \( U \in R[z], r \in \mathbb{N} \)
Output: A Gröbner basis as in Lemma 7 of the solution module \( M = \{(a, b) \in R[z]^2 \mid a U \equiv b \mod z^{r}\} \).

\[ \text{Springer} \]
We compute the discrepancy for every element in $B$. Now, the new discrepancies are obtained as:

\[
\begin{aligned}
\text{Example 1}
\end{aligned}
\]

Let $R = \text{GR}(4, 2) = \mathbb{Z}_4[\alpha]$ where $\alpha^2 + \alpha + 1 = 0$. We use Algorithm 1 to find a Gröbner basis of

\[
M = \{ (a, b) \in R[z]^2 | a ((3\alpha + 3)z + 1) \equiv b \mod z^2 \}
\]

with respect to the term order $<_\ell$ for $\ell = -1$. Hence, $U = (3\alpha + 3)z + 1$.

The initial ordered basis of $M^{(0)}$ is

\[
\mathcal{B}_0 = \{ [1, 0], [2, 0], [0, 1], [0, 2] \}.
\]

We compute the discrepancy for every element in $\mathcal{B}_0$ and find $[1, 2, 3, 1]$. Now, as $[1, 0] <_{-1} [0, 1]$ we get $[0, 1] - \frac{3}{2} [1, 0] = [1, 1]$ as a new basis element. Similarly, as $[1, 0] <_{-1} [0, 2]$ we get $[0, 2] - \frac{2}{3} [1, 0] = [2, 2]$. From $[1, 0]$ and $[2, 0]$ we further get $[z, 0]$ and $[2z, 0]$. So, the new basis is, after reordering,

\[
\mathcal{B}_1 = \{ [1, 1], [2, 2], [z, 0], [2z, 0] \}.
\]

Now, the new discrepancies are $[3\alpha + 3, 2\alpha + 2, 1, 2]$. As $[1, 1] <_{-1} [z, 0]$ and $[1, 1] <_{-1} [2z, 0]$ we get new basis elements $[z, 0] - \frac{1}{3\alpha + 3} [1, 1] = [z + 3\alpha, 3\alpha]$ and $[2z, 0] - \frac{2}{3\alpha + 3} [1, 1] = [2z + 2\alpha, 2\alpha]$, and from $[1, 1]$ and $[2, 2]$ we get $[z, z]$ and $[2z, 2z]$. Thus finally, the basis found is

\[
\mathcal{B}_2 = \{ [z + 3\alpha, 3\alpha], [2z + 2\alpha, 2\alpha], [z, z], [2z, 2z] \}.
\]

In the next result we establish the minimality of $[\varphi, \omega]$ among the regular elements of the solution module of the key equation (9) with respect to the term order $<_{-1}$.

**Theorem 2** Let $M = \{ (a, b) \in R[z]^2 | a U \equiv b \mod z^{\ell + 1} \}$. Let $(a, b) \in M$ such that $\delta a \leq \frac{\ell + 1}{2}, \delta b \leq \frac{\ell}{2}$, and $2 \in (a, b)$. Suppose further that $\text{lc}(a) \in R^\times$ if $\delta a > \delta b$ and $\text{lc}(b) \in R^\times$ if $\delta a \leq \delta b$.

(a) Then $(a, b)$ is minimal in $M \setminus M \cap 2R[z]^2$ with respect to the term order $<_{-1}$. Moreover, if $(a', b')$ is minimal in $M \setminus M \cap 2R[z]^2$ then $[\mu a, \mu b] = v[\mu a', \mu b']$ for some $v \in K^\times$.

(b) If in addition $(a, b) = R[z]$ holds, then $(a, b)$ is minimal in $M \setminus \{ 0 \}$ with respect to the term order $<_{-1}$, and if $(a', b')$ is minimal in $M \setminus M \cap 2R[z]^2$ then $(a, b) = \theta[a', b']$ for some $\theta \in R^\times$.

**Proof** Let $(u, v) \in M \setminus \{ 0 \}$ satisfy $\text{lt}(u, v) <_{\ell} \text{lt}(a, b)$. Then $(u, v) \in M \cap 2R[z]^2$. We have $ub = av \mod z^{\ell + 1}$ and first we will establish equality in $R[z]$. 

\[ \square \]
Case 1: \( \text{lt}[a, b] = [z^\delta a, 0] \).
If \( \text{lt}[u, v] = [z^\delta u, 0] \) then \( \delta u < \delta a \) and \( \delta v \leq \delta u + \ell \), hence \( \delta v < \delta a + \ell \).
If \( \text{lt}[u, v] = [0, z^\delta v] \) then \( \delta u + \ell < \delta v \) and \( \delta v \leq \delta a + \ell \), hence \( \delta u < \delta a \).
We obtain
\[
\delta u + \delta b < \delta a + \delta b \leq t \quad \text{and} \quad \delta a + \delta v \leq 2\delta a + \ell \leq t + 1 + \ell.
\]
Case 2: \( \text{lt}[a, b] = [0, z^\delta b] \).
If \( \text{lt}[u, v] = [z^\delta u, 0] \) then \( \delta u < \delta b \) and \( \delta v \leq \delta u + \ell \), hence \( \delta v < \delta b \).
If \( \text{lt}[u, v] = [0, z^\delta v] \) then \( \delta u + \ell < \delta v \) and \( \delta v < \delta b \), hence \( \delta u + \ell < \delta b \).
We obtain
\[
\delta u + \delta b < 2\delta b - \ell \leq t - \ell \quad \text{and} \quad \delta a + \delta v < \delta a + 2\delta b \leq t.
\]
For \( \ell = -1 \) we get \( \delta(ub) \leq t \) and \( \delta(av) \leq t \) in all cases and therefore \( ub = av \) in \( R[z] \).

Since \( 2 \in (a, b) \), there exist \( f, g \in R[z] \) such that \( af + bg = 2 \). Then \( a(fu + gv) = 2u \) and \( b(fu + gv) = 2v \). Suppose that \( fu + gv \neq 0 \). Then, in Case 1 we have \( \delta a > \delta b \), thus \( \text{lc}(a) \in R^\times \) by assumption, and we get \( \delta a \leq \delta(a(fu + gv)) = \delta(2u) \leq \delta u \), contradicting \( \delta u < \delta a \). Similarly, in Case 2 we have \( \delta a < \delta b \), thus \( \text{lc}(b) \in R^\times \), and we get \( \delta b \leq \delta(b(fu + gv)) = \delta(2v) \leq \delta v \), contradicting \( \delta v < \delta b \). Therefore, we have \( fu + gv = 0 \) and hence \( 2u = 2v = 0 \). It follows \( [u, v] \in M \cap 2R[z]^2 \), as desired.

(a) The above shows that \([a, b]\) in minimal in \( M \setminus M \cap 2R[z]^2 \). Now suppose there exists \([a', b'] \in M \setminus M \cap 2R[z]^2 \) such that \( \text{lt}[a', b'] = \text{lt}[a, b] \). We note that
\[
\text{lc}[a, b] = \begin{cases} \text{lc}(a) \in R^\times & \text{if } \delta a > \delta b, \\ \text{lc}(b) \in R^\times & \text{if } \delta a \leq \delta b, \end{cases}
\]
and thus \( [a, b] \) is a unit. Hence there exist \( \theta \in R \) such that \( [a', b'] = \theta[a, b] + [r, s] \) and \( \text{lt}[r, s] < \text{lt}[a, b] \). From the minimality of \([a, b] \) we deduce that \([r, s] \in M \cap 2R[z]^2 \), and so \( [\mu a', \mu b'] = \mu \theta[\mu a, \mu b] \). Since \( [\mu a', \mu b'] \neq 0 \) we have \( \mu \theta \neq 0 \), and hence \( v = \mu \theta \in K^\times \) and \( \theta \in R^\times \).

(b) Since \( (a, b) = R[z] \) there exist \( f, g \in R[z] \) such that \( af + bg = 1 \). Let \( [u, v] \in M \setminus [0] \) satisfy \( \text{lt}[u, v] < \_ \_ \_ \_ \text{lt}[a, b] \) and consider the above proof. We get \( a(fu + gv) = u \) and \( b(fu + gv) = v \), and as before we can prove \( fu + gv = 0 \). Hence \( u = v = 0 \), and hence \([a, b] \) is minimal in \( M \setminus [0] \). Now suppose there exists \([a', b'] \in M \setminus M \cap 2R[z]^2 \) such that \( \text{lt}[a', b'] = \text{lt}[a, b] \). As shown in (a) there exist \( \theta \in R^\times \) such that \([a', b'] = \theta[a, b] + [r, s] \) and \( \text{lt}[r, s] < \text{lt}[a, b] \). Now from the minimality of \([a, b] \) we deduce \([r, s] = 0 \).

\( \square \)

**Corollary 4** Let \( M = \{[a, b] \in R[z]^2 \mid a(1 + T) \equiv b \mod z^t+1\} \), and let \([a', b'] \) be the minimal regular element of a Gröbner basis of \( M \).

(a) Then \( [\mu \varphi, \mu \omega] = v[\mu a', \mu b'] \) for some \( v \in K^\times \).

(b) If \( e \) contains no ‘double-errors’, then \([\varphi, \omega] = \theta[a', b'] \) for some \( \theta \in R^\times \).

**Proof** Let \( w := w(e) = \delta \sigma \leq t \) be the number of errors occurred. If \( w \) is odd, then \( \delta \varphi = \frac{w+1}{2} \) and \( \delta \omega \leq \frac{w}{2} \), hence \( \delta \varphi > \delta \omega \) and \( \text{lc}(\varphi) \in R^\times \). If \( w \) is even, then \( \delta \varphi = \frac{w}{2} \) and \( \delta \varphi \leq \frac{w}{2} \), hence \( \delta \varphi \leq \delta \omega \) and \( \text{lc}(\omega) \in R^\times \). By Corollary 3, we have \( 2 \in (\varphi, \omega) \). So we can apply Theorem 2 with Remark 2.

\( \square \)
We note that since \( \omega(0) = \varphi(0) = 1 \) we may choose \([a', b']\) such that \( a'(0) = b'(0) = 1 \), and then we have \([\mu \varphi, \mu \omega] = [\mu a', \mu b']\) and \([\varphi, \omega] = [a', b']\), respectively.

### 7 Decoding \( \mathbb{Z}_4 \)-linear negacyclic codes

Let the \( \mathbb{Z}_4 \)-linear negacyclic code \( C \) be given as in the previous sections, and let \( v, c, e \in \mathbb{Z}_4[z] \), \( \sigma, \sigma_o, \sigma_e, \varphi, \omega \in \mathbb{R}_z \) and \( T \in \mathbb{R}(z) \) be given as before. In particular, \( v = c + e \) with \( c \in C \) and the error vector \( e \) is of Lee weight at most \( t \). Let \( M = \{[a, b] \in \mathbb{R}_z \mid a(1 + T) = b \mod z^{t + 1}\} \) be the module of solutions to the key equation, Eq. 9. We first compute a Gröbner, basis of \( M \) relative to the term order \( <_{-1} \), which contains an element \([a, b]\) such that \( \mu a = \mu \varphi \) and \( \mu b = \mu \omega \). Then \( \mu \varphi, \mu \omega \) can be used to determine \( \mu \sigma = \prod_{i=0}^{n-1}(1 - \mu X_i z)^{w(e_i)} \in \mathbb{K}[z] \) via the equations

\[
\mu \sigma = \mu \sigma_e + \mu \sigma_o, \quad \mu \sigma_e(z) = \mu \omega(z^2), \quad \text{and} \quad \mu \varphi(z^2) = \mu \sigma_e(z) + z \mu \sigma_o(z).
\]

Knowledge of \( \mu \sigma \) is not sufficient to recover the error pattern \( e \), as errors of the form \( e_j = \pm 1 \) cannot be distinguished. However, by examining the roots of \( \mu \sigma \) we find all error positions, and by examining the double roots we get all locations \( j \) where \( e_j = 2 \) (i.e., the ‘double-errors’).

Let \( e^2 \in \mathbb{Z}_4^n \) be defined by \( e^2_j = 2 \) if \( e_j = 2 \) and \( e^2_j = 0 \) otherwise. Note that \( e^2 \) is completely determined by the roots of \( \mu \sigma \). Now consider the word \( v' := v - e^2 = c + e' \) with \( e' := e - e^2 \). Then \( e' \) does not contain double-errors and has Lee weight at most \( t \). Then, using Corollary 4, the error pattern \( e' \) can be found by computing the minimal regular element of a Gröbner basis.

We outline the steps of the algorithm below.

**Algorithm 2** (Algebraic decoding of \( \mathbb{Z}_4 \) negacyclic codes) Let \( C \) be a negacyclic code over \( \mathbb{Z}_4 \) of length \( n \), whose generator polynomial has roots \( \alpha, \alpha^3, \ldots, \alpha^{2t-1} \) for a primitive \( 2n \)th root of unity \( \alpha \in \mathbb{R} \) such that \( \alpha^n = -1 \).

Input: \( v \in \mathbb{Z}_4[z] \) such that \( d(v, C) \leq t \)

Output: \( c \in \mathbb{C} \) such that \( w(v - c) \leq t \)

1. Compute the syndromes \( s_k := v(\alpha^k) \) for \( k = 1, 3, \ldots, 2t-1 \).
2. Compute the coefficients \( u_k \) using Eq. 6 for \( k = 1, 3, \ldots, 2t-1 \). Let \( u := \sum_{k=1}^{2t-1} u_k z^k \).
3. Compute \( T(z) \mod z^{t+1} \) from \( u \) using Eq. 7.
4. Obtain a solution \([g, h] \in \mathbb{R}[z]^2\) of the key equation \( a(1 + T) = b \mod z^{t+1} \) satisfying the hypothesis of Theorem 2. One way to do this is to identify the minimal regular element of a Gröbner basis of the solution module \( M \), relative to the term order \( <_{-1} \).
5. Compute \( \mu \sigma(z) = \mu \sigma_e(z) + \mu \sigma_o(z) := \mu h(z^2) + z^{-1} (\mu g(z^2) - \mu h(z^2)) \).
6. Evaluate \( \mu \sigma(\mu \alpha^{-j}) \) for \( j = 0, \ldots, n-1 \).
   - If \( \mu \alpha^{-j} \) is a double root of \( \mu \sigma \) then \( e_j = 2 \).
   - If \( \mu \alpha^{-j} \) is a single root of \( \mu \sigma \) then \( e_j \in \{\pm 1\} \).
7. Let \( e^2 := \sum_{j,e_j=2} z^j \), and let \( v' := v - e^2 \).
8. Repeat Steps 1.–4. with \( v' \) in place of \( v \), and compute \( \sigma'(z) = \sigma'_e(z) + \sigma'_o(z) := h(z^2) + z^{-1} (g(z^2) - h(z^2)) \).
9. Compute \( e' \) by evaluating \( \sigma'(\alpha^{-j}) \) and \( \sigma'(\alpha^{-j+n}) \) for \( j = 0, \ldots, n-1 \).
10. Output $c := v' - e'$.

We will conclude our work by a concrete example.

**Example 2** Let $R = \text{GR}(4, 4) = \mathbb{Z}_4[v]$ where $v^4 = 2v^2 + v + 3$. We use a code of length $n = 15$ and designed error-correcting capability $t = 3$. Then $\alpha := -v$ is a primitive 30th root of unity such that $\alpha^{15} = -1$. Let the received word be $v = 3 + 2x + x^2 + 3x^3 + 4x^4 + x^5 + 2x^7 + 2x^8 + x^9 + 3x^{12}$.

1. The list of syndromes is $[s_1, s_2, s_3] = [3v^3 + 3v^2 + 1, 3v^3 + 3v + 2, 2v^3 + 3v^2 + v]$.  
2. We find $[u_1, u_3, u_5] = [v^3 + v^2 + 3, 2v^3 + 2v^2 + 2v, 2v + 2]$.  
3. We find $[T_1, T_2, T_3] = [v^3 + 2v^2 + 3v, v^3 + 3v^2 + 3v + 2, 3v^3 + 3v^2 + 1]$; the key equation now to solve is $a(1 + T_1)z + T_3z^3 + T_2z^3 = b \mod z^4$.  
4. Considering the solution module $M = ([a, b] \in R[z] | a(1 + T) \equiv b \mod z^4)$ we use Algorithm 1 to compute a Gröbner basis for $M$ (with respect to the term order $<_\text{Gr}$), consisting of the element $[g, h] = [z^2 + (v^3 + v^2 + 3z)z + v^3 + 2v^2 + 3v + 2, (2v^3 + v^2 + 2v)z + v^3 + 2v^2 + 3v + 2]$, as well as $[2z + 2v^2, 2v^2], [z^3, z^2], \text{and } [z^2 + (3v^2 + 2)z, 2z^2 + (3v^2 + 2)z]$.  
5. We use the minimal regular element $[g, h]$ of the Gröbner basis to compute the polynomial $s = z^3 + (2v^3 + v^2 + 2v)z^2 + (3v^3 + v + 3)z + v^3 + 2v^2 + 3v + 2$. After normalization we find $s' = (v^3 + 3v^2 + 2v)z^3 + (2v^3 + v^2 + 2v + 3)z^2 + (v^3 + v^2 + 3)z + 1$ such that $\mu \sigma = \mu s' = (\mu^3 + 3\mu^2)z^2 + (\mu^3 + 2\mu + 3)z + 1$.  
6. We find $\mu \alpha^{-13}$ as a double root. The vector of 'double-errors' is thus $e^2 = 2x^4$.  
7. Now we repeat this process with $v' = v - e^2$.

8. We find $[s_1, s_2, s_3] = [3v^3 + 3v^2 + 2v + 3, v^3 + 2v^2 + v, 2v^3 + v^2 + 3v], [u_1, u_3, u_5] = [v^3 + v^2 + 2v + 1, 0, 0]$, and $[T_1, T_2, T_3] = [v^3 + 2v^2 + v, 3v^3 + v^2 + v + 2, 3v^3 + 3v^2 + 2v + 3]$. The Gröbner basis of the corresponding solution module consists of the elements $[z + 3v^2, 3v^2], [z^2 + 2v^2, 2v^2], [z^3, z^2]$, and $[2z^3, 2z^2]$. By using the element $[g, h] = [z + 3v^2, 3v^2]$ we find $\alpha' = (z + 3v^2)(3v^2)^{-1} = (v^3 + 2v + 2v + 1)z + 1$.  
9. We find $-\alpha^{-13}$ as root, hence the vector of 'single-errors' is $e' = 3x^{13}$.  
10. The vector $v$ will be decoded to the codeword $c = v' - e' = v - e^2 - e' = 3 + 2x + x^2 + 3x^3 + 4x^4 + x^5 + 2x^7 + 2x^8 + x^9 + 3x^{12} + x^{13}$.

**Remark 3** In the above example it turns out that $-\alpha^{-13}$ is also a root of the polynomial $s$ (or $s'$) computed in Step 5, so there was no need to solve another key equation (Steps 7 and 8). This phenomenon was also observed in numerous further experiments, so we conjecture that it is not necessary to solve the second key equation in general. A correctness proof (as an extension of Theorem 2 or Corollary 4) for this simplified algorithm was however not yet found.

On the other hand, the computed polynomial $s'$ and the actual error locator polynomial $\sigma$, while equal modulo 2, are different, as $\sigma = (1 - \alpha^4)z^2(1 + \alpha^{13}z) = (3v^3 + v^2 + 2v + 2)z^3 + (3v^2 + 2v + 1)z^2 + (v^3 + v^2 + 3)z + 1$.
