INTRODUCTION

In 2009, Shanafelt and colleagues proposed that “wellness goes beyond merely the absence of distress and includes being challenged, thriving, and achieving success in various aspects of personal and professional life.” Siedsma and Emle defined it as “the complex and multifaceted nature of physicians’ physical, mental and emotional health, and well-being.” The American College of Emergency Physicians (ACEP) proposed a multidimensional wellness model in 2016, the components of which are the following: occupational, emotional, physical, financial, spiritual, social, and intellectual. When viewing this model, it is clear how these areas are interconnected and critical in a physician’s everyday life and that any approach to well-being must offer a holistic approach incorporating the different psychosocial aspects affecting the physician. Despite these and other frameworks, no clear consensus definition of well-
being exists in the academic medical literature. Well-being is comprised of multiple variables including work-life balance, quality of life, resilience, mindfulness, coping strategies, and mood. In this review we explore the tools that assess the positive states of physician well-being.

The importance of physician well-being has now been universally recognized, with calls to action made by virtually every major medical society, including the American Medical Association, the Association of American Medical Colleges, and the Accreditation Council for Graduate Medical Education and in emergency medicine (EM) by the Council of Residency Directors (CORD), ACEP, and the Society for Academic Emergency Medicine. Whether wellness and well-being can be taught remains to be determined, and there is no standard for assessment or improvement. Numerous studies have looked at various aspects, but either due to small or specific sample size or confounding factors that lacked consideration, interpretation of and extrapolation of the results of these interventions should be done with caution.

Summary

Well-being is a complex and multifactorial topic. Accurate measurement is key to conducting needs assessments, developing appropriate interventions, and ongoing monitoring. There are numerous tools available for assessment. The goal of the Assessment Tools Workgroup, a sub-committee of the CORD Resilience Committee, was to research and summarize the various assessment tools available on burnout, well-being, resilience, and related factors and compile them as a collated resource. This is the second resource available in this series; it focuses on assessment tools to measure well-being, resilience, and other positive states. For assessment tools related to burnout and negative states, please refer to “The Assessment of Physician Well-being, Part One: Burnout and Other Negative States.”

METHODS

The instruments included in this article are the result of a scoping review of English-language publications with abstracts indexed in PubMed, Web of Science, and MedEd Portal within the past 10 years. Searches were based on the main Medical Library Subject Heading (MeSH) terms “resilience,” “mindfulness,” “mood,” “personality,” “well-being,” “quality of life,” and “stress.” In addition to the search on the main term, subheadings included the following: measurement, assessment, evaluation, diagnosis, education, etiology, trends, derivation, validation, tool, instrument, scale, measure, survey, or questionnaire AND resident, residency, intern, internship, medical student, clerk, attending, physician and clinician. A complete listing of search terms can be found in Appendix 1. This search was augmented by reviewing article reference lists and performing further citation searches. We did not include instruments cited only in abstracts or as reports of meetings.

Abstractors performed a comprehensive review of the identified assessment tools. Details of all scales and where they can be found are presented in Table and Appendix 2. The tools identified as most relevant, accessible, and practical in evaluating emergency physician (EP) well-being were included for further review. The tools were selected by multiple abstractors. Abstractors worked in groups of two or three and focused on one subject (e.g., mindfulness or quality of life). Discrepancies between abstractors were reviewed by either the first, second, or last author on the manuscript. Consensus between at least two reviewers was required for an instrument to be included in this paper.

The primary inclusion criteria was use of the tool in a physician population in the medical literature. Exclusion criteria included tools that were not used in a physician population or were not cited in the medical literature relating to physicians more than two to three times. Tools that did not meet these two criteria are referenced in Appendix 2. The figure illustrates the search algorithm and tool selection process. The articles reviewed were organized by subcategory of the tool (e.g., mindfulness tools), then by individual tool, and finally, by the populations the tool had been used in.

A summary of the scale’s purpose, structure, and evidence of its psychometric properties were derived from the original source references. Due to the varied psychometric properties of each tool, abstractors relied on the reported validity and reliability from the source manuscripts. Where available, published cutoff scores are provided for guidance, although their validity or utility in other clinical or research contexts should not be assumed. Where psychometric properties were not explicitly described in the primary sources, potential users may need to check for any subsequent information pertaining to reliability and validity.

The following comments and discussions should be read in conjunction with the details reported in Table and Appendix 2, as well as with the recommendations provided at the end of the review.

RESULTS

Well-being Factors and Quality of Life Tools

While the definition of job burnout is relatively clear, well-being has been viewed through various domains and used interchangeably with quality of life (QOL). Higher perception of work-life imbalance negatively impacts work satisfaction and effect of work on QOL. Several authors investigating well-being in physicians used instruments initially intended for the general population or patients, while others derived instruments that specifically address the physician population.

Physician Wellness Inventory

The Physician Wellness Inventory (PWI) is a measure of how happy and satisfied physicians are with their work. The PWI was piloted to assess attendings, residents and
| Name of instrument | Brief description | Number of items | Time to complete | Cost | Where to find it | Notes | Pros | Cons |
|--------------------|------------------|-----------------|-----------------|------|-----------------|-------|------|------|
| Well-being and quality of life | It has three scales: career purpose, cognitive flexibility and distress. | 14 items | Two minutes | free | www.promoteyourwellness.com/PWI.docx | | There are only two published studies using this instrument | | Free Developed for physicians Limited studies, need more data on reliability and validity |
| Physician Wellness Inventory | Used to: 1) stratify physician well-being in several important dimensions; and 2) identify physicians whose degree of distress may negatively impact their practice. | Seven Items | < Five minutes | Free for individuals | https://www.mededwebs.com/employee-well-being-index | Designed to measure burnout, provide valuable resources when people them the most, and track progress over time to promote self-awareness. | Short | More useful for screening than detailed testing |
| Quality of Life Linear Analog Scale Assessment (LASA) | LASA includes five simple items, each of which targets a specific domain of quality of life. | Five items | < Five minutes | Free | http://www.jpsmjournal.com/article/S0885-3924(07)00463-0/pdf | Specific domains include physical well-being (i.e., fatigue, activity level), emotional well-being (i.e., depression, anxiety, stress), spiritual well-being (i.e., sense of meaning, relationship with God), and intellectual well-being (i.e., ability to think clearly, concentrate). | Short | Multiple forms exist |
| Professional Quality of Life Scale (ProQOL) | Self-report measure that asks the respondent to reflect on his or her experiences at work as a human service provider, both positive and negative, in the past 30 days. | 30 items | 5-10 minutes | Free, must credit the author | http://www.proqol.org/Home_Page.php | The ProQOL consists of three separate subscales: Compassion Satisfaction, Burnout, and Secondary Traumatic Stress. Standardized scores exist for all three (< 23 = low, 23-41 = average, > 41 = high). No composite score is available. It is recommended to complete the measure in its entirety rather than separate the questions into separate tests divided by subscale. | Free Validated Good reliability | Indirect measure of “wellness” |
| Name of instrument | Brief description | Number of items | Time to complete | Cost | Where to find it | Notes | Pros | Cons |
|--------------------|------------------|-----------------|-----------------|------|-----------------|-------|------|------|
| Epworth Sleepiness Scale (ESS) | Self-reported measure of how easily a person can fall asleep in different situations | Eight items | One minute | Free (for individual use) | http://epworthsleepinessscale.com/about-the-ess/ | The ESS specifically distinguishes reports of dozing behavior from feelings of fatigue and drowsiness/sleepiness | Free | Quick and easy to use | Risk for bias |
| Resilience and mindfulness | Connor Davidson Resilience Scale (CD-RISC) | Used for clinical practice as a measure of stress and adaptability. Also used to evaluate response to clinical interventions. | 25 items | 5-10 minutes | Need agreement from authors with small fee | http://www.connordavidson-resilience.com/index.php | The scale has been developed and tested as a measure of degree of resilience. The scale also has promise as a method to screen people for high, intermediate or low resilience. | Well validated | Small fee. | Initial intent to use on patients with mental illness. | Limit use in physicians. | |
| Perceived Stress Scale (PSS) | Used to measure the perception of stress; measure of the degree to which situations in one’s life are appraised as stressful; items are designed to tap how unpredictable, uncontrollable and overloaded respondents find their lives; direct queries of current experienced stress | 14 items | 10-15 minutes | Free | http://www.psy.cmu.edu/~scohen/scales.html | A psychometrically sound global measure of perceived stress that could provide valuable information about the relationship between stress and pathology (correlations between high perceived stress and burnout). | Free | Short | Easy to use |
| Coping Inventory for Stressful Situations (CISS) | The CISS measures three types of coping styles: task-oriented coping, emotion-oriented coping, and avoidance-oriented coping. It helps you determine the preferred coping style. | 48 items | 10 minutes | CISS Manual = $57 | http://www.mhs.com | Offers precision in predicting preferred coping styles, and contributes to understanding the differential relationships between coping styles and other personality variables. | Reliable and valid | Cost | Not validated in a physician population |
| Name of instrument                  | Brief description                                                                 | Number of items | Time to complete | Cost                     | Where to find it                              | Notes                                                                 | Pros                                | Cons                                    |
|------------------------------------|-----------------------------------------------------------------------------------|-----------------|------------------|--------------------------|-----------------------------------------------|----------------------------------------------------------------------|--------------------------------------|-----------------------------------------|
| Ways of Coping Scale (WAYS)        | The Ways of Coping Questionnaire is a 66-item instrument containing a wide range of thoughts and acts that people use to deal with the internal and/or external demands of specific stressful encounters. | 66 items        | 10 minutes       | $50 for the manual       | http://www.mindgarden.com/158-ways-of-coping-questionnaire | An assessment of coping in relation to a specific stressful encounter. Not designed to be used as an assessment of coping styles or traits. | Well validated                       | Cost                                    |
| The COPE Inventory (brief)         | The COPE Inventory is a multidimensional coping inventory to assess the different ways in which people respond to stress. | 28 items        | 15 minutes       | Free                    | www.psy.miami.edu/faculty/ccarver/sdBrCOPE.html | Five scales (of four items each) measure conceptually distinct aspects of problem-focused coping (active coping, planning, suppression of competing activities, restraint coping, seeking of instrumental social support) | Free                                | Not validated in a physician population. |
| Mood and personality               | Introspective self-assessment tool that identifies psychological preferences in how people interact with their environments and make decisions. | 93 items        | 15 minutes       | $49.95 per user         | https://www.cpp.com/products/mbti/index.aspx | Provides insight into an individual’s personality traits, can help us identify weaknesses and be better communicators and decision makers | Widely used and highly regarded      | Cost                                    |
| Myers-Briggs Type Indicator (MBTI) |                                                                                  |                 |                  |                          |                                               | Validated                                                                 | Good reliability                     |                                         |
| Name of instrument | Brief description | Number of items | Time to complete | Cost | Where to find it | Notes | Pros | Cons |
|--------------------|------------------|----------------|-----------------|------|-----------------|-------|------|------|
| Profile of Mood States (POMS 2) | Self-report psychological rating scale use to assess transient, distinct mood states. Measures multiple dimensions of mood over a distinct period of time which include: Anger-Hostility, Confusion-Bewilderment, Depression-Dejection, Fatigue-Inertia, Tension-Anxiety, Vigor-Activity and Friendliness. | Full version: 65 items | Full version: 10 minutes | Manual $92, and Single full or short form $3.50 | https://ecom.mhs.com(S(4srbwc3qmfsjjpo454qlycu))/inventory.aspx?gr=cli&prod=poms2&id=pricing&RptGrpID=pmr | Provides insight into an individual’s current mood state and how that may affect their performance at work and interaction with others. | Allows for real-time assessment of risks for burnout, second victim syndrome, etc. | Not well validate in physician population |
| Thomas-Kilmann Conflict Mode Instrument (TKI) | Self-assessment tool that identifies individual conflict-handling styles, which are categorized into 5 "modes": competing, collaborating, compromising, avoiding, and accommodating | 30 item | 15 minutes | $18.95 each, $179 pack of 10 | https://www.cpp.com/en/tkitems.aspx?ic=4813 | Provides a pragmatic, situational approach to conflict resolution, change management, leadership development, and communication | Relevant | Cost validated in physician populations |
Figure 1. Flow diagram of literature search algorithm and assessment tool selection.
fellows from three academic centers in Michigan in 2010. The first and only study that used the PWI was performed in randomly selected full-time physician members of the American Academy of Family Physicians to assess the relationship between burnout and happiness. They found that career purpose was the strongest predictor of happiness. No other studies have evaluated the reliability and validity of this instrument. The major advantage of the PWI is that it was developed for physicians, taking into consideration their work settings and relationship to patients.

**Physician Well-being Index**

The authors at the Mayo Clinic School of Medicine developed the Physician Well-Being Index (PWBI) specifically for medical professionals, including resident and medical student versions. The purpose of the index is to stratify physician well-being in several important dimensions and to identify physicians whose degree of distress may negatively impact their practice (career satisfaction, intent to leave current position, medical errors). The seven-item survey includes domains of burnout, depression, stress, fatigue, and mental and physical QOL.

**Quality of Life Linear Analog Self-assessment**

The Quality of Life Linear Analog Self-Assessment (QOL LASA) scales have repeatedly been used in the literature to evaluate QOL in the cognitive, physical, emotional, social, or spiritual domains. In medical oncologists, high QOL LASA scores were associated with higher work satisfaction. One study employed the QOL LASA to measure the outcomes of a well-being initiative in a group of 40 internal medicine (IM) physicians who subsequently demonstrated a significant increase in QOL LASA scores post-intervention group. QOL LASA scores have been shown to be negatively correlated with self-perceived error reporting in several studies.

**Professional Quality of Life Scale**

The Professional Quality of Life Scale (ProQOL) is the current iteration of several previously developed scales related to compassion fatigue including the Compassion Fatigue Scale, the Compassion Fatigue Self-Test, and the Compassion Satisfaction and Compassion Fatigue Test. ProQOL is a well-validated, 30-item scale that consists of three separate subscales: compassion satisfaction; burnout; and secondary traumatic stress. There are over 650 citations related to ProQOL, and its previous iterations in the medical literature. Key literature can be found here: http://www.proqol.org/uploads/ProQOL_Concise_2ndEd_12-2010.pdf. The ProQOL scale allows for monitoring of both the negative consequences (e.g., burnout and secondary traumatic stress) and protective qualities (e.g., compassion and satisfaction) of being in a caring profession.

**Epworth Sleepiness Scale**

Fatigue has long been linked to well-being and QOL. Sleep loss and fatigue have a significant negative impact on resident quality of life and perception of well-being. The Epworth Sleepiness Scale (ESS) is the most widely used tool to evaluate daytime sleepiness in a variety of populations and cultures. In multiple medical student studies, there were high rates of daytime sleepiness, higher levels of burnout, and academic performance. Increased sleepiness has been shown to be related to an increase in motor vehicle accidents among IM residents, with higher levels of stress and fatigue being independently associated with self-perceived medical errors.

In a study with EM residents, sleep deprivation was found to significantly impact resident lives both personally and professionally with many social activities and meaningful personal pleasures being deferred or postponed during residency. Additionally, residents in that study reported that sleep loss and fatigue had a major impact on their ability to perform their work. While baseline characteristics have not been established and cross-specialty studies have not been done, one study of IM residents found that 23% had an abnormal ESS score.

**Coping Tools: Resilience and Mindfulness**

EPs are subjected to high-stress situations on a regular basis. Stress is not burnout but a natural response defined as a state of mental or emotional strain or tension resulting from adverse or very demanding circumstances. Reaction to stressors is highly individualized, and numerous emotional and physical disorders have been linked to stress. Understanding the response to stress can provide insight into specific behavioral modifications that can be used to cope with stress in more positive ways.

There are numerous types of coping mechanisms, some positive and associated with increased mindfulness and resilience, and some negative, which worsen symptoms of burnout. Resilience, too, is a unique and central component of well-being, identified as “the ability of an individual to respond to stress in a healthy, adaptive way such that personal goals are achieved at minimal psychological and physical cost.” It is increasingly recognized as a strategy that may reduce physician stress, particularly burnout, anxiety, and depression. In one study conducting semi-structured interviews with a variety of physicians, self-awareness, self-monitoring, and mindfulness-based, stress-reduction techniques were determined to be as effective as techniques to reduce the negative feelings of emotional distress and consequent rumination while enhancing a physician’s capacity for empathy. This notion of self-awareness and self-care is thought to be teachable and can be enhanced, as demonstrated by one pilot study involving family medicine residents.
Lall et al. Assessment of Physician Well-being, Part Two: Beyond Burnout

**Perceived Stress Scale**

The Perceived Stress Scale (PSS) measures the degree to which situations in one’s life are viewed as stressful. This tool was designed with the intent of creating a psychometrically sound global measure of perceived stress that could provide information on the relationship between stress and pathology. The PSS has been widely used across the globe and most frequently with university students and those attempting to stop smoking. There are multiple studies on resident physicians who have used the PSS as an assessment of their well-being. In several of these studies, perceived overall stress was strongly related to work hours and was found to affect physicians more than other healthcare professionals (e.g., nurses). Resident physicians who screen positive for burnout also have higher perceived levels of stress, a pattern similarly shown in faculty physicians. Resident physicians have also been noted to have higher perceived levels of stress than matched controls in the general population. In several studies with nurses and faculty physicians, implementation of a resiliency program has shown improvement in scores on the PSS.

The PSS is a highly reliable and valid measure of stress in adults across multiple ethnicities. It provides individuals insight into their typical stress-response state. This awareness, in turn, may potentially increase mindfulness and be used to target relaxation behaviors to relieve stress. A potential limitation of the PSS is that the initial intent of the tool was to link stress to pathologic behavior, particularly tobacco abuse. However, many studies in the medical literature have used the PSS to assess patients pre- and post-intervention for multiple disease processes. If one considers burnout symptoms pathological insofar as they have been linked to issues such as substance abuse, medical error, and poor patient satisfaction, then this limitation is of debatable significance.

**Coping Inventory to Stressful Situations**

The Coping Inventory to Stressful Situations (CISS) measures three types of coping styles when one encounters a stressful or challenging situation: emotion-oriented; task-oriented; and avoidance-oriented coping. It also measures distraction and social diversion. The tool is aimed at determining an individual’s preferred coping style to provide a better understanding of the relationship between that individual’s coping style and his or her personality. The results can be used to help intervention planning for individuals in stressful situations. There is also a modified 21-item tool for specific social situations or interpersonal conflicts (CISS: Situation- Specific Coping Measure [CISS:SSCM]).

The CISS and CISS:SSCM are reliable measures of coping styles, demonstrating internal consistency, test-retest reliability, and item-remainder correlation. The CISS scales also have demonstrated construct validity as assessed by factor analysis in adults, undergraduates, and adolescents. Data from the study of medical students and physicians in practice have shown that task-oriented coping plays a role in reducing burnout symptoms, while emotion-oriented and avoidance-oriented coping may do the opposite. Therefore, the CISS may be a valuable tool in identifying individuals who may require additional training in specific coping strategies to improve their resilience and/or reduce their risk of burnout.

In a study of 616 emergency department (ED) personnel, increased levels of burnout were associated with emotion-oriented coping while decreased levels were observed in those with task-oriented coping. This was also demonstrated in a study of 50 IM physicians. The CISS has also been used to study medical students, demonstrating a correlation of task-oriented coping with higher levels of emotional intelligence. Emotional intelligence — the ability to perceive, process, and regulate emotions effectively — is thought to be a strong predictor of resident well-being. Two other studies of medical students found that avoidance-oriented coping was associated with increased measure of fatigue and depressive symptoms.

**The Ways of Coping Checklist, the Ways of Coping (Revised), the Ways of Coping Scale**

The Ways of Coping Scales (WCCL, CAPS, WAYS) identify two distinct, general types of coping: problem-focused and emotion-focused. Problem-focused coping is aimed at problem solving or doing something to alter the source of stress. Emotion-focused coping is aimed at reducing or managing the emotional distress that is associated with or cued by the situation. While most stressors will elicit both types of coping, problem-focused coping tends to predominate when the individual feels as if...
something constructive can be done, leading to engagement of
the problem, and emotion-focused coping predominates when
the individual believes the stressor is something that must be
endured, leading to problem avoidance and disengagement. 55,56
The Ways of Coping measures are not designed to assess coping
traits and/or style. Each administration of the tool is aimed at
understanding the coping processes an individual engages in a
particular stressful encounter rather than attempting to define their
coping style or traits.

The CAPS measure has potential benefit in prospectively
identifying individuals with more emotion-focused coping
strategies who may be at risk of burnout. Its main limitation
is that this tool is situation-specific and does not reflect
the complexity of the situations in medical practice nor
encompass the entirety of an individual coping skillset. Its
strength lies in making an individual aware of how he or
she copes with different, specific, stressful situations and
providing language around coping responses that may be more
mindful, healthful, and productive for them, their team, and
their patients.

Coping Orientation to Problems Experienced

The Coping Orientation to Problems Experienced (COPE)
Inventory and, more recently, the Brief COPE were designed
to assess the different ways in which people respond to stress.
This tool looks at many dimensions of coping, including both
functional and dysfunctional responses. These dimensions
include the following: active coping; planning; suppression of
competing activities; restraint coping; seeking social support
for instrumental reasons; seeking social support for emotional
reasons; focusing on and venting emotions; behavioral
disengagement; positive reinterpretation and growth; denial,
acceptance; and turning to religion. 59,60

The COPE Inventory was validated in a population of
almost 1,000 undergraduate students in its final iteration.
The authors state there is no such thing as an “overall” score
on this measure and do not recommend a particular way
of generating a dominant coping style for a given person.
Instead, they advocate looking at each scale separately to see
how it relates to the other variables. Thus, this tool may help
with insight into coping response and personal reflection.

The Brief COPE has been used in studies involving
IM and EM residents. In the study with IM residents,
those residents who employed the strategies of acceptance,
active coping, and positive reframing had lower emotional
exhaustion and depersonalization, suggesting that residents
who place a high priority on healthful relationships, engage in
spiritual activities, and practice humility may have important
coping mechanisms that mitigate burnout. 56,58,59 Residents
who employed denial, disengagement, self-blame, and
humor were found to have higher emotional exhaustion and
depersonalization. Disengagement and venting were found to
be negatively correlated with personal accomplishment.

These tools are relatively short, free, and easy to use.
They provide individuals with insight into their typical
coping responses, thereby increasing mindfulness. Although
used in physician populations, they have not been validated
specifically in physician populations.

Mood and Personality Tools

Personality typing is a psychological concept popularized
in the 1940s. Conceptually, it is founded on the notion that
individuals favor certain psychological preferences and that
personality traits affect how they perceive and interact with
their environments. The ED is a unique medical environment
where there is great emphasis on leadership, communication,
and teamwork. The application of personality and mood
assessment instruments may provide useful information about
individual ED providers and create a more dynamic, efficient,
and sound working environment.

Myers-Briggs Type Indicator

The Myers-Briggs Type Indicator (MBTI) is the most
widely used of the personality assessment tools. This
introspective, self-assessment tool separates people into
dichotomies that each focus on a particular aspect of
information processing: extraversion/introversion; sensing/
intuition; thinking/feeling; and judging/perceiving. In the
medical community, the MBTI has been studied in medical
students, dental students, and resident and attending physician
populations, primarily among surgeons and anesthesiologists.
Many researchers have applied the MBTI to assess for
personality patterns among different specialties and identify
personalities at increased risk for burnout. 61-64 While the MBTI
is the oldest and most well-studied in the physician population,
it has yet to be shown how MBTI results can be implemented to
benefit individual practitioners and the work environment.

Profile of Mood States

The Profile of Mood States (POMS) is a self-report,
psychological rating scale that assesses multiple dimensions of
mood over a distinct period of time. Such mood states include
the following: anger-hostility, confusion-bewilderment,
depression-dejection, fatigue-inertia, tension-anxiety,
vigor-activity, and friendliness. The dynamic nature of the
assessment may allow for real-time evaluation for risks of
burnout and second- victim syndrome following an unforeseen
or unfavorable outcome.

While the tool has been used in several physician
communities, 65-71 it is not well validated in the medical
field. 72-76 The enthusiasm of IM interns was found to give
way to sustained depression, anger, and fatigue at the end of
internship. 67 A study of early-career physicians showed that
acute sleep deprivation secondary to long call hours negatively
affected mood. 65 In one study of IM residents, mood
disturbances were identified as common, and the decline in
empathic concern was specifically found to persist throughout training unlike other mood disturbances that were no longer present by the end of residency.67

Thomas-Kilmann Conflict Mode Instrument

The Thomas-Kilmann Conflict Mode Instrument (TKI) is a self-assessment tool that identifies individual conflict-handling styles, which are categorized into five “modes”: competing, collaborating, compromising, avoiding, and accommodating. Conflict is inevitable in any team-based field due to personality and work-style differences. EPs manage the expectations and reactions of patients in crisis. Patient-centered care requires collaboration between the clinicians, patients, family, and other providers, which may lead to another source of conflict.

The TKI has been validated in the medical population including nurses, residents, board-certified physicians, hospital administrators, and program directors, although not specifically among emergency clinicians.77-80 In studies of resident physicians, there is a tendency for higher levels of accountability and successful execution of administrative tasks in individuals with collaborating or competing conflict modes.78-79 Identifying individual conflict-management styles, the TKI can help provide insight to EPs regarding their strengths and potential weakness in dealing with conflict, which may ultimately help them become better leaders in the department and better team players.

LIMITATIONS

There are an overwhelming number of assessment tools available in the literature that can be used to measure the different components of physician well-being. While our literature search was methodical and broad, we acknowledge that we may have missed some key assessment tools. At times, a single author determined the inclusion eligibility of the tools identified in our literature search strategy. However, consensus between at least two reviewers was required for an instrument to be included in this paper.

Assessment tools must be suitable for and validated in the population of interest. A majority of the tools we found have been used in a physician population but have never been validated in this population. Many of the tools have been designed for and validated in special populations; however, their applicability, reliability, and validity in a physician population is not clearly demonstrated in the medical literature. In the absence of independent validation, the results of these tools should be interpreted with caution.

Physician well-being is multifactorial, and it is difficult to purely divide these components by topic or sub-category as they have a complex interplay with one another. We have reviewed the tools based on the well-being topics that were most commonly found in the medical literature and that were of highest potential value. Very few tools exist that were either designed for use in a physician population or have been validated in physicians. We have highlighted the tools from each topic that are most relevant for use in assessing an EP population.

CONCLUSION

Physician well-being is a complicated topic, and there is no standardized approach for assessing it. We provide a framework of the assessment tools that can be used to evaluate the positive states of physician well-being. The assessment tools reviewed vary in the topic assessed, cost, length, and applicability to a physician population. This manuscript is intended to provide the reader with several available options for evaluating different components of physician well-being. It is at the discretion of the reader to determine which tool would be most appropriate for the outcome he or she is trying to measure. There is great opportunity for the development of new tools and validation of those that are already in use.

There is clearly much to be done in the development of resources to mitigate burnout, foster resilience, and improve well-being. When undertaking an assessment of physician well-being, it is of critical importance to understand what you want to assess and to ensure you have selected the best tool to assess it. We hope this manuscript gives emergency physicians a starting point to evaluate their own well-being and the well-being of their peers, trainees, and students.
