Analytical approximation for $\langle \phi^2 \rangle$ of a quantized scalar field in ultrastatic asymptotically flat spacetimes

Arkady A. Popov
Department of Mathematics, Kazan State Pedagogical University, Mezhlauk 1 st., Kazan 420021, Russia

Analytical approximations for $\langle \phi^2 \rangle$ of a quantized scalar field in ultrastatic asymptotically flat spacetimes are obtained. The field is assumed to be both massive and massless, with an arbitrary coupling $\xi$ to the scalar curvature, and in a zero or nonzero temperature vacuum state. The expression for $\langle \phi^2 \rangle$ is divided into low- and high-frequency parts. The expansion for the high-frequency contribution to this quantity is obtained. This expansion is analogous to the DeWitt-Schwinger one. As an example, the low-frequency contribution to $\langle \phi^2 \rangle$ is calculated on the background of the small perturbed flat spacetime in a quantum state corresponding to the Minkowski vacuum at the asymptotic. The limits of the applicability of these approximations are discussed.

I. INTRODUCTION

The investigations of black hole evaporation and particle production by an expanding universe have acted as a stimulus for a detailed and systematic investigation of the theory of quantum fields propagating on curved spacetimes. The main objects to calculate from quantum field theory in curved spacetime are the quantities $\langle \phi^2 \rangle$ and $\langle T_{\mu \nu} \rangle$ where $\phi$ is the quantum field and $T_{\mu \nu}$ is the stress-energy tensor operator for $\phi$. The renormalized stress-energy tensor $\langle T_{\mu \nu} \rangle$ is an important quantity for the construction of a self-consistent model of an evaporating black hole, while the mean-square field $\langle \phi^2 \rangle$ plays a role in the study of theories with spontaneous symmetry breaking. The functional dependence $\langle T_{\mu \nu} \rangle$ on metric $g_{\mu \nu}$ allows us to study the evolution of the background geometry driven by the quantum fluctuation of the matter fields propagating on it. This is the so-called backreaction, governed by the semiclassical Einstein equations

$$G_{\mu \nu} = 8\pi \langle T_{\mu \nu} \rangle. \tag{1}$$

However, the exact results for $\langle \phi^2 \rangle$ and $\langle T_{\mu \nu} \rangle$ in four dimensions are not numerous (see, for example, [1]). Numerical computations of these quantities are as a rule extremely intensive [2, 3, 4]. One of the most widely used techniques to obtain information about these quantities is the DeWitt-Schwinger (DS) expansion [5]. It may be used to give the expansions for $\langle \phi^2 \rangle$ and $\langle T_{\mu \nu} \rangle$ in terms of powers of the small parameter

$$\frac{1}{mL} \ll 1, \tag{2}$$

where $m$ is the mass of the quantized field and $L$ is the characteristic scale of change of the background gravitational field [6].

The analytical approximations to $\langle \phi^2 \rangle$ and $\langle T_{\mu \nu} \rangle$ for the conformally coupled massless fields [3, 4, 7, 8, 9, 10, 11, 12] give good results. Nevertheless, there still remains the problem of the extension of this type approximations’ applicability limits. If the quantum field is massive but the mass of the field does not satisfy the condition $\frac{1}{mL} \ll 1$, the analytical approximations to $\langle \phi^2 \rangle$ and $\langle T_{\mu \nu} \rangle$ are even less numerous [3, 4, 11, 12, 13, 14].

In this paper, approximate expressions for $\langle \phi^2 \rangle_{\text{ren}}$ of a quantized scalar field in ultrastatic asymptotically flat spacetimes are derived. The field is assumed to be both massless or massive with an arbitrary coupling $\xi$ to the scalar curvature $R$, and in a zero or nonzero temperature vacuum state. The expression for $\langle \phi^2 \rangle_{\text{ren}}$ is divided into low- and high-frequency parts. The Bunch-Parker approach [15] is used for derivation of high-frequency contributions (HFC) to these quantities. As in the case of massless field the quantum state of the field with mass $m \ll 1/L$ is essentially determined by the topology of spacetime and the boundary conditions. In this paper such dependence is determined by the low-frequency contribution (LFC). As an example, this contribution is calculated on the background of the small perturbed flat spacetime in quantum state corresponding to the Minkowski vacuum at the asymptotic.
The paper is organized as follows. In Sec. II the expressions for the Euclidian Green’s function of a scalar field with arbitrary mass and curvature coupling in a ultrastatic spacetime is divided into low- and high-frequency parts. In Sec. III the WKB approximation of the high-frequency contribution to \( \langle \varphi^2 \rangle \) is derived. The low-frequency contribution is derived and the renormalization procedure is described in Sec. IV. The results are summarized in Sec. V. In the Appendix the expanding of renormalization counterterm for \( \langle \varphi^2 \rangle \) in powers of coordinate difference of the separated points is described. The units \( \hbar = c = G = k_B = 1 \) are used throughout the paper. The sign conventions are those of Misner, Thorne and Wheeler [16].

II. GREEN’S FUNCTION

The metric in Euclidean section for an ultrastatic spacetime is given by

\[
d s^2 = d \tau^2 + g_{a b} d x^a d x^b ,
\]

where \( \tau = i t \) is the Euclidean time, \( g_{a b} \) are arbitrary functions of spatial coordinates \( x^1, x^2, x^3 \). (Latin indices run from 1 to 3, Greek indices run from 0 to 3.)

In this paper, the point-splitting method is employed for the regularization of ultraviolet divergences. When the points are separated one can show that

\[
\langle \varphi^2 \rangle_{\text{unren}} = G_E(x^\mu, \tilde{x}^\nu).
\]

The Euclidean Green’s function \( G_E \) is a solution of the equation

\[
(\Box_x - m^2 - \xi R(x^a)) G_E(x^\mu, \tilde{x}^\nu) = - \frac{\delta(\tau, \tilde{\tau}) \delta^{(3)}(x^a, \tilde{x}^b)}{\sqrt{g^{(3)}(x^a)}}, \tag{5}
\]

where \( m \) is the mass of the scalar field, \( \xi \) is its coupling to the scalar curvature \( R(x^a) \), \( g^{(3)}(x^a) = \det g_{a b}(x^1, x^2, x^3) \).

If the scalar field is at zero temperature then \( \delta(\tau, \tilde{\tau}) \) and \( G_E(x^\mu, \tilde{x}^\nu) \) can be expanded as

\[
\delta(\tau, \tilde{\tau}) = \frac{1}{2 \pi} \int_{-\infty}^{+\infty} d \omega e^{i \omega (\tau - \tilde{\tau})}, \tag{6}
\]

\[
G_E(x^\mu, \tilde{x}^\nu) = \frac{1}{2 \pi} \int_{-\infty}^{+\infty} d \omega e^{i \omega (\tau - \tilde{\tau})} \tilde{G}_E(\omega; x^a, \tilde{x}^b). \tag{7}
\]

If the field is at temperature \( T \), then the Green’s function is periodic in \( \tau - \tilde{\tau} \) with period \( 1/T \). In this case \( \delta(\tau, \tilde{\tau}) \) and \( G_E(x^\mu, \tilde{x}^\nu) \) have the expansions

\[
\delta(\tau, \tilde{\tau}) = T \sum_{n = -\infty}^{\infty} \exp[i \omega_n (\tau - \tilde{\tau})], \tag{8}
\]

\[
G_E(x^\mu, \tilde{x}^\nu) = T \sum_{n = -\infty}^{\infty} \exp[i \omega_n (\tau - \tilde{\tau})] \tilde{G}_E(\omega_n; x^a, \tilde{x}^b), \tag{9}
\]

where \( \omega_n = 2 \pi n/T \). In both cases \( \tilde{G}_E(\omega; x^a, \tilde{x}^b) \) satisfies the equation

\[
\frac{1}{\sqrt{g^{(3)}(x^a)}} \frac{\partial}{\partial x^a} \left( \sqrt{g^{(3)}(x^c)} g^{a b}(x^c) \frac{\partial}{\partial x^b} \tilde{G}_E(\omega; x^a, \tilde{x}^b) \right) - (\omega^2 + m^2 + \xi R) \tilde{G}_E(\omega; x^a, \tilde{x}^b)
\]

\[
= - \frac{\delta^{(3)}(x^a, \tilde{x}^b)}{\sqrt{g^{(3)}(x^a)}}. \tag{10}
\]

In the case \( m \gg 1/L \), where \( L \) is a characteristic scale of the variation of the background gravitational field, it is possible to construct the iterative procedure of the solution of this equation with small parameter \( 1/mL \). This procedure gives the standard expansion of \( \langle \varphi^2 \rangle_{\text{unren}} \) in terms of powers of \( mL \).
In the case
\[ m \ll \frac{1}{L} \] (11)
a small parameter of iterative procedure does not exist. Nevertheless, let us divide \( G_E \) into low- and high-frequency parts, as it was done in [12]

\[ G_E(x^\mu, \tilde{x}^\nu) = G_E^{LFC}(x^\mu, \tilde{x}^\nu) + G_E^{HFC}(x^\mu, \tilde{x}^\nu), \] (12)

where

\[ G_E^{LFC}(x^\mu, \tilde{x}^\nu) = \frac{1}{\pi} \int^{1/\lambda_0}_0 d\omega \cos[\omega(\tau - \tilde{\tau})] \tilde{G}_E(\omega; x^a, \tilde{x}^b), \] (13)

\[ G_E^{HFC}(x^\mu, \tilde{x}^\nu) = \frac{1}{\pi} \int^{\infty}_{1/\lambda_0} d\omega \cos[\omega(\tau - \tilde{\tau})] \tilde{G}_E(\omega; x^a, \tilde{x}^b) \] (14)

if the scalar field is at zero temperature and

\[ G_E^{LFC}(x^\mu, \tilde{x}^\nu) = T \tilde{G}_E(0; x^a, \tilde{x}^b) + 2T \sum_{n=1}^{n_0-1} \cos[\omega_n(\tau - \tilde{\tau})] \tilde{G}_E(\omega_n; x^a, \tilde{x}^b), \] (15)

\[ G_E^{HFC}(x^\mu, \tilde{x}^\nu) = 2T \sum_{n=n_0}^{\infty} \cos[\omega_n(\tau - \tilde{\tau})] \tilde{G}_E(\omega_n; x^a, \tilde{x}^b) \] (16)

if the field is at temperature \( T \). Then the expansion of \( G_E^{HFC}(x^\mu, \tilde{x}^\nu) \) in terms of powers of a small parameter

\[ \varepsilon_{WKB} = \frac{\lambda_0}{L} \ll 1 \] (17)

can be obtained by analogy with the methods of evaluation of the DeWitt-Schwinger expansion. If the field is at temperature \( T \) then

\[ \lambda_0 = \frac{1}{2\pi T n_0} \] (18)

and

\[ \varepsilon_{WKB} = \frac{1}{2\pi T n_0 L} \ll 1. \] (19)

Below the main points of the Bunch and Parker approach [15] for obtaining \( G_E^{HFC}(x^\mu, \tilde{x}^\nu) \) are outlined.

**III. HIGH-FREQUENCY CONTRIBUTION TO \( \langle \phi^2 \rangle \)**

Let us introduce Riemann normal coordinates \( y^a \) in 3D space with origin at the point \( \tilde{x}^a \) [17]. In these coordinates one has

\[ g_{ab}(y^a) = \eta_{ab} - \frac{1}{3} R_{abcd} y^c y^d + O(y^3), \] (20)

\[ g^{ab}(y^a) = \eta^{ab} + \frac{1}{3} R^{ab}_{cd} y^c y^d + O(y^3), \] (21)

\[ g^{(3)}(y^a) = 1 - \frac{1}{3} R_{ab} y^a y^b + O(y^3), \] (22)
The function transformation 

\[ \overline{G}(\omega; y^a) = \sqrt{g^{(3)}(y)} \tilde{G}_\mu(\omega; y^a) \]  

and retaining in (10) only terms with coefficients involving two derivatives of the metric or fewer one finds that \( \overline{G}(\omega; y^a) \) satisfies the equation

\[ \eta^{ab} \frac{\partial^2 \overline{G}_0(\omega; y^a)}{\partial y^a \partial y^b} - \omega^2 \overline{G}_0(\omega; y^a) = -\delta^{(3)}(y). \]  

Note that quantities \( R_{abcd}, R_{ab}, R \) evaluated in metric (3) and those, evaluated in 3D metric \( g_{ab} \) coincide. Let us present

\[ \overline{G}(\omega; y^a) = \overline{G}_0(\omega; y^a) + \overline{G}_1(\omega; y^a) + \overline{G}_2(\omega; y^a) + \ldots, \]  

where \( \overline{G}_i(\omega; y^a) \) has a geometrical coefficient involving \( i \) derivatives of the metric at point \( y^a = 0 \). Then these functions satisfy the equations

\[ \eta^{ab} \frac{\partial^2 \overline{G}_0(\omega; y^a)}{\partial y^a \partial y^b} - \omega^2 \overline{G}_0(\omega; y^a) = -\delta^{(3)}(y), \]  

\[ \eta^{ab} \frac{\partial \overline{G}_1(\omega; y^a)}{\partial y^a \partial y^b} - \omega \overline{G}_1(\omega; y^a) = 0, \]  

\[ \eta^{ab} \frac{\partial \overline{G}_2(\omega; y^a)}{\partial y^a \partial y^b} - \omega \overline{G}_2(\omega; y^a) + \frac{1}{3} R^{a}_{\ c \ b \ d} y^c y^d \frac{\partial^2 \overline{G}_0(\omega; y^a)}{\partial y^a \partial y^b} \]  

\[ - \left[ m^2 + \left( \xi - \frac{1}{3} \right) R \right] \overline{G}_0(\omega; y^a) = 0. \]  

The function \( G_0(\omega; y^a) \) satisfies the condition

\[ R^{a}_{\ c \ d} y^c y^d \frac{\partial^2 G_0(\omega; y^a)}{\partial y^a \partial y^b} - R^a_{\ b \ c} y^b \frac{\partial G_0(\omega; y^a)}{\partial y^c} = 0, \]  

since \( G_0(\omega; y^a) \) is the function only of \( \eta_{ab} y^b \). Therefore Eq. (28) may be rewritten

\[ \eta^{ab} \frac{\partial^2 \overline{G}_2(\omega; y^a)}{\partial y^a \partial y^b} - \omega \overline{G}_2(\omega; y^a) + \frac{1}{3} R^{a}_{\ b \ c} y^c \frac{\partial \overline{G}_0(\omega; y^a)}{\partial y^b} \]  

\[ - \left[ m^2 + \left( \xi - \frac{1}{3} \right) R \right] \overline{G}_0(\omega; y^a) = 0. \]  

Let us introduce the local momentum space associated with the point \( y^a = 0 \) by making the 3-dimensional Fourier transformation

\[ \overline{G}_i(\omega; y^a) = \int \frac{dk_1 dk_2 dk_3}{(2\pi)^3} \exp(ik_3 y^a) \overline{G}_i(\omega; k^a). \]  

It is not difficult to see that

\[ \overline{G}_0(\omega; k^a) = \frac{1}{k^2 + \omega^2}, \]  

\[ \overline{G}_1(\omega; k^a) = 0. \]
where \( k^2 = \eta^{ab} k_a k_b \). In momentum space Eq. (31) gives

\[
- (k^2 + \omega^2) \overline{G}_2(\omega; k^a) = \frac{1}{3} R^a_b k_a \frac{\partial \overline{G}_0(\omega; k^a)}{\partial k_b} - (m^2 + \xi R) \overline{G}_0(\omega; k^a) = 0.
\]  

(34)

Hence

\[
\overline{G}_2(\omega; k) = \frac{-m^2 - \xi R}{(k^2 + \omega^2)^2} + \frac{2}{3} \frac{R^{ab} k_a k_b}{(k^2 + \omega^2)^3}.
\]  

(35)

Substituting (31), (32), (33), (35) in (25) and integrating leads to

\[
\overline{G}(\omega; y^a) = \int_{-\infty}^{+\infty} \frac{dk_1 dk_2 dk_3}{(2\pi)^3} \exp(\imath k_a y^a) \left[ - \frac{1}{k^2 + \omega^2} \frac{m^2 + \xi R}{(k^2 + \omega^2)^2} + \frac{2}{3(2k^2 + \omega^2)^3} \right]
\]

\[
= \frac{1}{8\pi \exp(|\omega|y)} \left[ \frac{-m^2 - (\xi - 1/6)R}{|\omega|} + \frac{2}{\eta y} + \frac{R^{ab} y^a y^b}{6 y} \right],
\]

(36)

where \( y = \sqrt{\eta_{ab} y^a y^b} \). Using the definition of \( \overline{G}(\omega; y^a) \) (22) and expansion (22) one finds

\[
\tilde{G}_E(\omega; y^a) = \left( 1 + \frac{1}{6} R_{ab} y^a y^b \right) \overline{G}(\omega; y^a)
\]

\[
= \frac{1}{8\pi \exp(|\omega|y)} \left[ \frac{-m^2 - (\xi - 1/6)R}{|\omega|} + \frac{2}{\eta y} + \frac{R^{ab} y^a y^b}{6 y} \right].
\]

(37)

The necessary condition for the validity of this approximation is

\[
\omega > \frac{1}{\lambda_0} \gg \frac{1}{L}.
\]

(38)

Hence one can evaluate \( G_E^{\text{HFC}} \) if the field is at zero temperature

\[
G_E^{\text{HFC}}(\Delta \tau, y^a) = \frac{1}{\pi} \int_{1/\lambda_0}^{\infty} \frac{d\omega \cos[\omega \Delta \tau]}{\omega^2} \tilde{G}_E(\omega; y^a)
\]

\[
= \frac{1}{8\pi^2} \left\{ \left[ m^2 + \left( \xi - \frac{1}{6} \right) R \right] \left[ C + \frac{1}{2} \ln \left| \frac{(y^2 + \Delta \tau^2)}{\lambda_0^2} \right| \right] - \frac{2}{\eta \lambda_0} + \frac{1}{\lambda_0^2} + \frac{2}{(y^2 + \Delta \tau^2)} + \frac{R^{ab} y^a y^b}{6(y^2 + \Delta \tau^2)} \right\},
\]

(39)

where \( C \) is Euler’s constant, \( \Delta \tau = \tau - \hat{\tau} \).

If the field is at temperature \( T \) then the necessary condition for the validity of expression (37) is

\[
n \geq n_0 \gg \frac{1}{2\pi T L}
\]

(40)

and

\[
G_E^{\text{HFC}}(\Delta \tau, y^a) = 2T \sum_{n=n_0}^{\infty} \cos[\omega_n \Delta \tau] \tilde{G}_E(\omega_n; x^a, \hat{x}^b)
\]

\[
= \frac{1}{8\pi^2} \left\{ \left[ m^2 + \left( \xi - \frac{1}{6} \right) R \right] \left[ C + \frac{1}{2} \ln \left| (y^2 + \Delta \tau^2)(2\pi T)^2 \right| + \psi(n_0) \right] - 2\pi T \left[ n_0 - \frac{1}{2} \right] \frac{2}{\eta} + (2\pi T)^2 \left( n_0^2 - n_0 + \frac{1}{6} \right) + \frac{2}{(y^2 + \Delta \tau^2)} + \frac{R^{ab} y^a y^b}{6(y^2 + \Delta \tau^2)} \right\},
\]

(41)

where \( \psi(z) \) is the logarithmic derivative of the gamma function (i.e., the digamma function). The Plana sum formula \( \text{[18]} \) has been used to compute the sums over \( n \) in the last expression.
The behavior of low-frequency modes is determined by the boundary conditions and the topological structure of the spacetime. As an example, let us consider the evaluation of the low-frequency contribution to the zeroth-order term of this expansion will be used for approximation of the low-frequency contributions to \( \langle \varphi^2 \rangle \). Below the zeroth-order term of this expansion will be used for approximation of the low-frequency contributions to \( \langle \varphi^2 \rangle \). This means that we choose the long-wave modes approximately coincident with long-wave modes of Minkowski vacuum. For these modes in a zero temperature quantum state

\[
\lambda \ll 1 \quad \text{or} \quad \lambda T n_0 \ll 1,
\]

the low-frequency contributions to \( \langle \varphi^2 \rangle \) can be expanded in terms of powers of this small parameter. Below the zeroth-order term of this expansion will be used for approximation of the low-frequency contributions to \( \langle \varphi^2 \rangle \). This means that we choose the long-wave modes approximately coincident with long-wave modes of Minkowski vacuum.

For these modes in a zero temperature quantum state

\[
G^{\text{LFC}}_E(\Delta \tau, y^a) = \frac{1}{(2\pi)^4} \int_{-1/\lambda_0}^{1/\lambda_0} d\omega \int_{-\infty}^{\infty} d^3p \exp \left( i\omega \Delta \tau + ip \tau \right) \frac{\exp \left( i\omega \Delta \tau + ip \tau \right)}{(\omega^2 + p^2 + m^2 + \mu^2)}
\]

\[
= \frac{1}{2\pi^2} \int_{-1/\lambda_0}^{1/\lambda_0} d\omega e^{i\omega \Delta \tau} \int_0^\infty dp \frac{p \sin(p \tau)}{y (\omega^2 + p^2 + m^2)}.
\]

In the limit \( \Delta \tau \to 0, \ y \to 0 \)

\[
G^{\text{LFC}}_E(\Delta \tau, y^a) = \frac{1}{2\pi^2} \left[ 2 \sin(\Delta \tau/\lambda_0) \frac{1}{y \Delta \tau} - \frac{1}{\lambda_0} \sqrt{\frac{1}{\lambda_0^2} + m^2} \right] - m^2 \ln \left| \frac{1/\lambda_0 + \sqrt{1/\lambda_0^2 + m^2}}{m} \right| + O(y)
\]

If we take into account conditions (41) and (47), i.e.

\[
m \ll \frac{1}{\lambda_0},
\]

then

\[
G^{\text{LFC}}_E(\Delta \tau, y^a) = \frac{1}{2\pi^2} \left\{ \frac{2}{y \lambda_0} \left[ 1 - \frac{2}{\lambda_0^2} \right] - \frac{1}{\lambda_0^2} \right\} - m^2 \left[ 1 + \ln \frac{4 \lambda_0 m^2}{\lambda_0^2 m^2} \right] + O(1) + O(\lambda^2 m^2).
\]

The analogous calculations for the temperature quantum state give

\[
G^{\text{LFC}}_E(\Delta t, y^a) = T \hat{G}_E(0; y^a) + 2T \sum_{n=1}^{n_0-1} \cos(\omega_n \Delta t) \hat{G}_E(\omega_n; y^a)
\]

\[
= \frac{1}{2\pi^2} \left\{ \frac{2}{\lambda_0^2} \left[ n_0 - \frac{1}{2} \right] - \frac{1}{\lambda_0^2} \right\} - m^2 \left[ 1 + \ln \frac{4 \lambda_0 m^2}{\lambda_0^2 m^2} \right] + O(1) + O(\lambda^2 m^2).
\]

The renormalization of \( \langle \varphi^2 \rangle_{\text{unren}} \) is achieved by subtracting the renormalization counterterm (48) and then letting \( \tilde{x}^\mu \to x^\mu \)

\[
\langle \varphi^2 \rangle_{\text{ren}} = \lim_{\tilde{x}^\mu \to x^\mu} \left[ \langle \varphi^2 \rangle_{\text{unren}} - \langle \varphi^2 \rangle_{\text{DR}} \right].
\]
where
\[
\langle \varphi^2 \rangle_{DS} = \frac{1}{8\pi^2} \sigma + \frac{1}{8\pi^2} \left[ m^2 + \left( \xi - \frac{1}{6} \right) R \right] C + \frac{1}{2} \ln \left( \frac{m_{\text{ren}}^2}{2\pi} \right)
\]
\[
- \frac{m^2}{16\pi^2} + \frac{1}{96\pi^2} R_{\mu\nu} \sigma^\mu \sigma^\nu,
\]
(49)

\(\sigma\) is one-half the square of the distance between the points \(x\) and \(\bar{x}\) along the shortest geodesic connecting them, \(\sigma^\mu\) is the covariant derivative of \(\sigma\), and the constant \(m_{\text{DS}}\) is equal to the mass \(m\) of the field for a massive scalar field. For a massless field \(m_{\text{DS}}\) is an arbitrary parameter due to the infrared cutoff in \(\langle \varphi^2 \rangle_{DS}\). A particular choice of the value of \(m_{\text{DS}}\) corresponds to a finite renormalization of the coefficients of terms in the gravitational Lagrangian and must be fixed by experiment or observation. The details of the calculations of \(\langle \varphi^2 \rangle_{DS}\) are discussed in Appendix:

\[
\langle \varphi^2 \rangle_{DS} = \frac{1}{8\pi^2} \left\{ \frac{2}{\sigma^2 + \Delta^2} + \left[ m^2 + \left( \xi - \frac{1}{6} \right) R \right] C + \frac{1}{2} \ln \left( \frac{m_{\text{ren}}^2}{4\pi^2} \right) \right\}
\]
\[
- \frac{m^2}{2} + \frac{R_{ab} y^a y^b}{6(y^2 + \Delta^2)} \right\}
\]
(50)

V. RESULTS

Using Eqs. (4), (12), (39), (46), (48) and (50) one finds
\[
\langle \varphi^2 \rangle_{\text{ren}} = \lim_{\Delta \to 0} \left[ G^{\text{LPC}}(\Delta \tau, y^a) + G^{\text{HPC}}(\Delta \tau, y^a) - \langle \varphi^2 \rangle_{\text{DS}} \right]
\]
\[
= \frac{R}{16\pi^2} \left( \xi - \frac{1}{6} \right) \ln \left| \frac{4(2\pi T)^2}{\lambda_0^4 m_{\text{DS}}^2} \right| + O \left( \frac{\varepsilon_{\text{WKB}}}{L^2} \right) + O \left( \frac{\lambda^2}{\lambda_0^2} \right).
\]
(51)

If the field is at temperature \(T\) then
\[
\langle \varphi^2 \rangle_{\text{ren}} = \frac{R}{16\pi^2} \left( \xi - \frac{1}{6} \right) \ln \left| \frac{4(2\pi T)^2}{m_{\text{DS}}^2} \right| + 2\psi(n_0)
\]
\[
+ \frac{(2\pi T)^2}{48\pi^2} + \frac{m^2}{8\pi^2} \left[ \psi(n_0) - \ln(n_0) + \frac{1}{2n_0} \right] + O \left( \frac{\varepsilon_{\text{WKB}}}{L^2} \right) + O \left( \lambda^2 T^4 n_0^4 \right).
\]
(52)

Let us cite the conditions of the validity of expressions (51), (52) once more
\[
m \ll \frac{1}{L},
\]
(53)
\[
\lambda \ll \lambda_0 \ll L \quad \text{or} \quad \lambda \ll \frac{1}{2\pi T n_0} \ll L.
\]
(54)

If also
\[
n_0 \gg 1,
\]
(55)
the digamma function \(\psi(n_0)\) is given by
\[
\psi(n_0) = \ln(n_0) - \frac{1}{2n_0} + O \left( \frac{1}{n_0^2} \right).
\]
(56)

Hence the expression (52) can be rewritten as
\[
\langle \varphi^2 \rangle_{\text{ren}} = \frac{R}{16\pi^2} \left( \xi - \frac{1}{6} \right) \ln \left| \frac{4(2\pi T)^2 n_0^2}{m_{\text{DS}}^2} \right| + \frac{(2\pi T)^2}{48\pi^2} + O \left( \frac{1}{n_0 L^2} \right)
\]
\[
+ O \left( \frac{\varepsilon_{\text{WKB}}}{L^2} \right) + O \left( \lambda^2 T^4 n_0^4 \right).
\]
(57)
The presence of the arbitrary parameter \( \lambda \) in the expressions \( 51 \) is a generic feature of local approximation schemes \( 3, 4, 10, 11, 12, 14, 20 \). For a conformally invariant field this parameter can be absorbed into the definition of constant \( m_{\text{gs}} \).

Note, that the approximation which corresponds to the analytical approximation of Anderson, Hiscock, and Samuel \( 3 \) for \( \langle \varphi^2 \rangle \) in case of ultrastatic asymptotically flat spacetime can be obtained by one use of the high-frequency approximation of \( G_\nu(\omega; y^\alpha) \) (see Eq. \( 37 \)) for all the values of \( \omega \). However the use of the high-frequency approximation of \( G_\nu(\omega; y^\alpha) \) for \( \omega \ll 1/\lambda_0 \) does not seem obvious. Nevertheless, in case of a conformally coupled massless field such procedure gives good results in the asymptotically flat region. \( 3, 10, 14 \).

**Appendix**

In this Appendix the expanding of \( \langle \varphi^2 \rangle_{y^\alpha} \) in powers of \( x^\alpha - \tilde{x}^\alpha \) is described.

Let points \( P(x) \) and \( \tilde{P}(\tilde{x}) \) be connected by the shortest geodesic \( x^\alpha = x^\alpha(s) \), where \( s \) is the canonical parameter. The functions \( x^\alpha(s) \) can be expanded in the Taylor series about point \( \tilde{P}(\tilde{x}) \)

\[
x^\alpha = \tilde{x}^\alpha + \frac{1}{1!} \frac{dx^\alpha}{ds} \Delta s + \frac{1}{2!} \frac{d^2 x^\alpha}{ds^2} (\Delta s)^2 + \frac{1}{3!} \frac{d^3 x^\alpha}{ds^3} (\Delta s)^3 + O((\Delta s)^4),
\]

where the coefficients are evaluated at \( \tilde{P}(\tilde{x}) \). Using the geodesic equation

\[
\frac{d^2 x^\alpha}{ds^2} + \Gamma^\alpha_{\beta\gamma} \frac{dx^\beta}{ds} \frac{dx^\gamma}{ds} = 0,
\]

one finds

\[
\frac{d^3 x^\alpha}{ds^3} = \left( -\partial_\gamma \Gamma^\alpha_{\sigma\beta} + 2 \Gamma^\alpha_{\sigma\beta} \Gamma^\beta_{\gamma\epsilon} \right) \frac{dx^\sigma}{ds} \frac{dx^\beta}{ds} \frac{dx^\gamma}{ds},
\]

where \( \partial_\gamma \) denotes the partial derivative with respect to \( x^\gamma \). Hence Eq. \( 41 \) can be rewritten

\[
x^\alpha = \tilde{x}^\alpha + \frac{1}{1!} u^\alpha \Delta s + \frac{1}{2!} \left( -\partial_\gamma \Gamma^\alpha_{\sigma\beta} + 2 \Gamma^\alpha_{\sigma\beta} \Gamma^\beta_{\gamma\epsilon} \right) u^\sigma u^\beta u^\gamma (\Delta s)^2 + O((\Delta s)^3),
\]

where \( u^\alpha = dx^\alpha/ds \). This equation can be inverted

\[
u^\alpha \Delta s = e^\alpha + \frac{1}{2} \Gamma^\alpha_{\beta\gamma} e^\beta + \left( \frac{1}{6} \Gamma^\alpha_{\sigma\beta} \Gamma^\beta_{\gamma\epsilon} + \frac{1}{6} \partial_\gamma \Gamma^\alpha_{\sigma\beta} \right) e^\sigma e^\beta e^\gamma + O(e^4),
\]

where \( e^\alpha = x^\alpha - \tilde{x}^\alpha \). If we use determinations \( \sigma^\mu \) and \( \sigma \) \( 21 \), we can write

\[
\sigma(x, \tilde{x}) = \frac{1}{2} g_{\alpha\beta} u^\alpha u^\beta (\Delta s)^2 = \frac{1}{2} g_{\alpha\beta} e^\alpha e^\beta + \frac{1}{2} g_{\alpha\beta} \Gamma^\alpha_{\gamma\delta} e^\gamma e^\delta + \frac{1}{6} g_{\alpha\beta} \Gamma^\alpha_{\gamma\delta} \Gamma^\gamma_{\epsilon\nu} e^\epsilon e^\nu + \frac{1}{8} g_{\alpha\beta} \Gamma^\alpha_{\gamma\delta} \Gamma^\gamma_{\epsilon\nu} e^\epsilon e^\nu + O(e^3).
\]

Hence the resulting expression for \( \langle \varphi^2 \rangle_{y^\alpha} \) is

\[
\langle \varphi^2 \rangle_{y^\alpha} = \frac{1}{4} \left( 1 - \frac{1}{6} \frac{g_{\alpha\beta} e^\alpha e^\beta}{g_{\alpha\beta} e^\alpha e^\beta} \right) + \frac{1}{2} \ln \left( \frac{m^2}{4 g_{\alpha\beta} e^\alpha e^\beta} \right) + C - \frac{m^2}{16 \pi^2} + \frac{1}{48 \pi^2} \frac{R_{\alpha\beta} e^\alpha e^\beta}{g_{\alpha\beta} e^\alpha e^\beta} + O(e).
\]
In coordinates \( \tau, y^a \), where \( y^a \) are the Riemann normal coordinates with origin at the point \( \tilde{x}^a \) in 3D space,
\[
\epsilon^0 = \Delta \tau, \quad \epsilon^a = y^a.
\]  
(A8)

At point \( \tilde{P} \) in these coordinates also \cite{17}
\[
\Gamma^a_{\beta\gamma} = 0
\]  
(A9)

and
\[
g_{\alpha\beta} \left( \partial_\gamma \Gamma^\gamma_{\alpha\beta} \right) \epsilon^\beta \epsilon^\gamma \epsilon^\delta = \frac{\eta_{ab}}{6} \left( R^a_{\ cde} + R^a_{\ cde} \right) y^b y^c y^d y^e = 0.
\]  
(A10)

After the substitution of these expressions into (A7) one finds that \( \langle \varphi^2 \rangle_{DS} \) has the form \cite{60}.

Acknowledgments

I would like to thank S. V. Sushkov and N. R. Khusnutdinov for helpful discussions. This work was supported by the Russian Foundation for Basic Research Grant No. 02-02-17177 and by the SRPED Foundation of Tatarstan Republic Grant No. 06-6.5-110.
