Abstract

Using an identity, directly derived from the Young-Laplace equation, the problem of the equilibrium shape of an axisymmetric sessile drop is reduced to a one-parameter shooting method problem. Based on the method the numerical solutions for drops with Bond number up to 15 are plotted. The agreement between the method and the ADSA-D method as well as the experimental data is tested. A Mathematica code based on the method is presented.

PACS: 47.55.D-, 47.85.Dh, 68.03.Cd
Keywords: Drops, Hydrostatics, Surface tension
1 Introduction

The problem of a drop on a horizontal surface with the effect of surface tension being balanced with gravity has been studied for more than a century. The early numerical solutions go back to 1883 \[1\], with updates by different authors \[2, 3, 4\]. Different perturbative treatments of the problem have been developed over the years, among them are those by \[5, 6, 7, 8, 9\] for small drops (small Bond number). As large drops (or vanishing surface tension drops) are theoretically an infinitely large and thin film of liquid subjected to the boundary conditions at the outer edge, the limit of large Bond number falls and has been studied in the context of singular perturbation problems \[10\]. Based on the similarity between the truncated oblate spheroid and drop’s shape, an approximated profile is suggested in \[11\] for the shape of the drop. In \[12\] a new numerical treatment of the problem is given based on a variational method to minimize the total energy of the drop, by which the use of the tables by \[11\] is more direct than the earlier treatments. As another effort in this direction, in \[13\] the singular perturbation technique is used to obtain the asymptotic expressions describing the shape of small sessile and pendant drops. The study of the profiles of resting drops in different situations is particularly important for practical purposes. In fact, one of the most common methods to measure the surface tension of liquids is based on the matching between calculated drop’s profiles and measured drop’s shapes. Over the years, the optimization of matching methods between the calculated profiles and the experimental data on drop’s profiles has been the subject of several research pieces \[14, 15, 16\].

Treating a sessile drop as a boundary value problem, it is shown that the multi-parameter shooting method is applicable (see e.g. \[17, 18, 19\]). It is the purpose of this note to show that a one-parameter shooting method is applicable to sessile drops as well. The reduction of parameters is the result of using an identity directly derived from the Young-Laplace equation \[20\]. By this identity the numerical procedure to reach the solution can be controlled by only one shooting parameter.

The scheme of the rest of this note is as follows. In Sec. 2 the basic notions are shortly reviewed. In Sec. 3 the mathematical setup as well as the derivation of the mentioned identity is presented. Sec. 4 is devoted to some results and comparisons with some available numerical and experimental data. In Appendix a code in Mathematica based on the developed shooting procedure is presented.

2 Basic notions

The shape of a drop of liquid on a solid surface, in the idealized case (absence of impurities and pinning effects), is determined by the quantities: 1) the surface tension of liquid $\gamma$, 2) the solid-liquid adhesion coefficient $\sigma$, 3) the shape of the solid surface, and due to the weight, 4) the drop’s volume. At the solid-liquid-vapor (s.l.v.) point of contact, the contact angle $\theta$ in the equilibrium condition
Three classes of the drop’s shape on a solid surface.

is given by the Young equation

\[ \cos \vartheta = \frac{\sigma}{\gamma} - 1. \]  

Three classes of possibilities for the contact angle are presented in Fig. 1.

At every point on the drop surface the Young-Laplace relation holds

\[ \gamma \left( \frac{1}{R_1} + \frac{1}{R_2} \right) = \Delta p \]  

in which \( \Delta p \equiv p_i - p_v \) is the pressure jump across the surface, and \((R_1, R_2)\) are two principal radii of curvature of the surface at the point. Provided by the hydrostatic laws, \( \Delta p \) is expressed in terms of the surface equation. Hence, the Young-Laplace relation is the partial differential equation which, accompanied by appropriate boundary conditions, determines the shape of the drop’s surface.

Heuristically, the final shape of drop is the result of the balance between the surface effects and the bulk ones. While the surface tension tends to decrease the surface of the drop, the adhesion coefficient tends to increase the surface of the contact region, and the gravity tends to lower the center of mass of the drop. In many practical cases the surface tension and the adhesion coefficient, though with opposite effects, may be considered at the same order, meaning \( \gamma \) and \( \sigma \) are comparable. For a drop with volume \( V \) and density \( \rho \), the so-called Bond number defined by the dimensionless combination \( V^{2/3} \rho g / \gamma \) would determine whether weight has the dominant contribution or not. When the weight is ignorable, only the contribution from the surface effects exist. Minimizing the area for a fixed volume, the drop’s surface is part of a sphere.

3 The mathematical setup

Using the cylindrical coordinate setup given in Fig. 2, the total curvature of a surface with azimuthal symmetry, represented by \( z = f(\rho) \) is given by

\[ \frac{1}{R_1} + \frac{1}{R_2} = \frac{1}{\rho} \frac{d}{d\rho} \left( \rho \frac{|f'|}{\sqrt{1 + f'^2}} \right), \]  

where \( f' = df/d\rho \). The pressure jump in presence of gravity gets contribution from the weight of the drop’s layers as well, leading to

\[ \Delta p(z) = \Delta p_r + \rho g (h - z) \]  

Figure 1: Three classes of the drop’s shape on a solid surface.
in which $h$ is the height of the drop’s apex, and $\Delta p_\gamma$ is a constant representing the pressure jump due to the surface tension. So, the Young-Laplace relation reads

$$\mp \frac{1}{\rho} \frac{d}{d\rho} \left( \rho \frac{f_\pm'}{\sqrt{1 + f_\pm'^2}} \right) = 2\kappa + \frac{\rho g}{\gamma} (h - f_\pm).$$

(5)

in which $f_+$ and $f_-$ are denoting the upper and lower parts of the drop, respectively (see Fig. 2b), and $\kappa := \Delta p_\gamma/(2\gamma)$. At apex ($h = f_+(0)$) we have $R_1 = R_2$, and so by (2), $\kappa$ is simply the curvature at apex of drop. We mention $f_+'>0$ and $f_-'>0$. The boundary conditions for $\vartheta > 90^\circ$ are:

$$f_+'(0) = 0 \quad (6)$$

$$f_-'(\rho_0) = -\tan \vartheta, \quad (7)$$

$$f_-(\rho_0) = 0. \quad (8)$$

In case with $\vartheta < 90^\circ$ (7) and (8) are valid for $f_+$.

The main issue with equation (5) is that the parameters $h$ and $\kappa$ are not known at the first place, and would be determined only after the complete solution is available. So at starting point the main equation is not fully known.

Further, the contact radius $\rho_0$ (Fig. 2), as the limiting value for the variable $\rho$, is not known at first place. These all indicate that the Young-Laplace equation can not be treated as straightforward as an ordinary boundary value problem.

As will be seen shortly, by integrating the Young-Laplace equation an identity is obtained which relates the three unknown parameters in a very helpful way. In what follows we mainly consider the case with $\vartheta > 90^\circ$. The generalization to case with $\vartheta < 90^\circ$ is rather straightforward. Integrating the Young-Laplace equation for the upper and lower parts of drop leads to

$$\rho_1 = \left( \kappa + \frac{\rho g}{2\gamma} h \right) \rho_0^2 - \frac{\rho g}{\gamma} \int_0^{\rho_1} \rho f_+(\rho) d\rho$$

(9)

$$\rho_1 - \rho_0 \sin \vartheta = \left( \kappa + \frac{\rho g}{2\gamma} h \right) (\rho_1^2 - \rho_0^2) - \frac{\rho g}{\gamma} \int_{\rho_0}^{\rho_1} \rho f_-(\rho) d\rho$$

(10)
in which we have used
\[
\frac{f'}{\sqrt{1 + f'^2}} \bigg|_{\rho_0} = -\tan \vartheta = \sin \vartheta
\] (11)
for \( \vartheta > 90^\circ \). Subtracting (9) and (10) gives
\[
\kappa + \frac{\rho g}{2\gamma} h = \sin \vartheta \rho_0 + \frac{\rho g V}{2\pi \gamma \rho_0^2}
\] (12)
in which we have used the relation for the volume of drop,
\[
\frac{V}{2\pi} = \int_0^{\rho_1} \rho f_+(-\rho) d\rho - \int_{\rho_0}^{\rho_1} \rho f_-(-\rho) d\rho.
\] (13)
It is easy to show that identity (12) is valid for the acute contact angle (\( \vartheta < 90^\circ \)) as well. It is reminded that in obtaining (12) no approximation is used, and so it is an exact relation.

Now, using the identity (12), the combination \( \kappa \) and \( h \) in right-hand side of (5) can be replaced in favor of \( \rho_0 \), and the Young-Laplace equation turns to:
\[
\mp \frac{1}{\rho} \frac{d}{d\rho} \left( \rho \frac{f'_\pm}{\sqrt{1 + f'^2_\pm}} \right) = 2 \left( \frac{\sin \vartheta}{\rho_0} + \frac{\rho g V}{2\pi \gamma \rho_0^2} \right) - \frac{\rho g}{
\gamma} f_\pm.
\] (14)
In above the only unknown parameter is \( \rho_0 \). For the case with \( \vartheta < 90^\circ \) only \( f_+ \) in above should be kept.

For later use, let us remind the spherical solution of weightless drop. It is easy to check that, by setting \( g = 0 \) and \( \kappa = 1/R \), the expression
\[
z = f_0\pm(-\rho) = z_0 \pm \sqrt{R^2 - \rho^2},
\] (15)
satisfies (5). The radius \( R \) is fixed by the volume of spherical cap,
\[
V = \frac{\pi}{3} R^3 (1 - \cos \vartheta)^2(2 + \cos \vartheta).
\] (16)
Following a simple geometrical argument in the sphere (Fig. 2), we have
\[
\begin{aligned}
\rho_0 &= R \sin \vartheta \\
z_0 &= -R \cos \vartheta \\
\rho_1 &= R \\
h &= R + z_0
\end{aligned}
\] (17)

As in case with \( \vartheta > 90^\circ \) around the equatorial radius \( \rho_1 \) (Fig. 2b) \( f'_\pm \to \mp \infty \), it would be convenient to switch to the spherical coordinates in which the whole surface of drop is covered by one function. Among many others, we found the choice illustrated in Fig. 3 more convenient, in which
\[
z = r(\theta) \sin \theta,
\]
\[
\rho = r(\theta) \cos \theta.
\] (18) (19)
In the new coordinates the Young-Laplace equation takes the following form

\[
\frac{\gamma}{r^2 \cos \theta} \left[ \frac{d}{d\theta} \left( \frac{r r' \cos \theta}{\sqrt{r^2 + r'^2}} \right) - \frac{2r^2 + r'^2}{\sqrt{r^2 + r'^2}} \cos \theta \right] = \Delta p_\gamma + \rho g (h - z), \tag{20}
\]

in which \( r' = dr/d\theta \). Using the identity (12) leads to

\[
\frac{d}{d\theta} \left( \frac{r r' \cos \theta}{\sqrt{r^2 + r'^2}} \right) - \frac{2r^2 + r'^2}{\sqrt{r^2 + r'^2}} \cos \theta = \left[ c r \sin \theta - 2 \left( \frac{\sin \vartheta}{\rho_0} + \frac{c V}{2\pi \rho_0^2} \right) \right] r^2 \cos \theta, \tag{21}
\]

in which \( c = g \rho_0 / \gamma \), the so-called the capillary constant. As we are considering axisymmetric drops, it is sufficient to restrict the polar coordinate \( \theta \) only to the left-side of drop,

\[
0 \leq \theta \leq 90^\circ. \tag{22}
\]

Using (6)-(8) and (18)-(19) the boundary conditions in new coordinates are found

\[
\begin{align*}
r'(0) &= -\rho_0 \cot \vartheta, \tag{23} \\
r(0) &= \rho_0, \tag{24} \\
r'(90^\circ) &= 0. \tag{25}
\end{align*}
\]

Therefore the shooting method by one controlling parameter \( \rho_0 \) can be employed to obtain numerical solutions of (21). The value of \( \rho_0^{\vartheta=0} = R \sin \vartheta \) of weightless drop can be chosen as the initial guess of the shooting parameter \( \rho_0 \). As it is known that, due to weight, the radius of contact region increases (see e.g. [20]), upon stepwise increasing of the parameter \( \rho_0 \) and checking the condition (25) at apex of drop, one can reach the desired accuracy.
4 Samples of solutions and comparisons

In order to assess the accuracy of the present method, the results based on it are compared with some available data. However, it would be illustrative to begin with a demonstration of the results based on the method. The numerical solutions of (21) with different Bond numbers for $\vartheta = 45^\circ$ and $\vartheta = 145^\circ$ are presented in Fig. 4 and Fig. 5, respectively. The presented plots cover Bond numbers from 0 to 15. As expected, by increasing the Bond number, the apex’s height decreases while contact radius, as well as equatorial radius for case with $\vartheta > 90^\circ$, increase.

As a further test, in Tab. 1 the results of application of one-parameter shooting method to (21) are compared with those by [18] by the ADSA-D method. The input values used by [18] are taken from the data generated by ALFI program. It is mentioned that the present method returns the correct values with negligible errors.

The comparison with some available experimental data with the values by

Table 2: The comparison between experimental data for drops with \( \theta < 90° \) and values by numerical solutions of [21]. For water drops: \( \varrho = 0.997 \text{ g/cm}^3 \), \( \gamma = 72.0 \text{ mJ/m}^2 \). For formamide drops: \( \varrho = 1.133 \text{ g/cm}^3 \), \( \gamma = 58.2 \text{ mJ/m}^2 \). For all drops: \( g = 980.7 \text{ cm/s}^2 \).

### A Mathematica code

Here a code in Mathematica based on the method is presented. In the below the following input values from Tab. 3 are taken: \( V = 0.0892 \text{ cm}^3 \), \( \gamma = 72.0 \text{ mJ/m}^2 \), \( g = 980.7 \text{ cm/s}^2 \), \( \varrho = 0.997 \text{ g/cm}^3 \), \( \theta = 117.34° \). The increasing step in \( \rho_0 \) is
Table 3: The comparison between experimental data for drops with \( \theta > 90^\circ \) and values by numerical solutions of (21). For water drops: \( \varrho = 0.997 \text{ g/cm}^3 \), \( \gamma = 72.0 \text{ mJ/m}^2 \). For mercury drops: \( \varrho = 13.55 \text{ g/cm}^3 \), \( \gamma = 480 \text{ mJ/m}^2 \). For all drops: \( g = 980.7 \text{ cm/s}^2 \).
