Eikonal Amplitude in the Gravireggeon Model at Superplanckian Energies

Abstract

The gravity effects in high-energy scattering, described by a four-dimensional eikonal amplitude related to gravireggeons induced by compact extra dimensions are studied. It is demonstrated that the real part of the eikonal (with a massless mode subtracted) dominates its imaginary part at both small and large impact parameters, in contrast to the usual case of hadronic high-energy behavior. The real part of the scattering amplitude exhibits an exponential falloff at large momentum transfer, similar to that of the imaginary part of the amplitude.

1 Introduction

In our previous paper [1], we considered the model with compact extra spatial dimensions [2] and calculated the contribution of Kaluza-Klein (KK) gravireggeons into the inelastic cross section of high energy scattering of four-dimensional SM particles. In particular, an expression for the imaginary part of the eikonal has been derived. The results were applied to cosmic neutrino gravitational interaction with atmospheric nucleons [1].

In the present paper, we study quantum gravity effects related to the extra dimensions in the real part of the eikonal. As in Ref. [1], the SM particles are confined on a four-dimensional brane, while the gravity lives in all $D = d + 4$ dimensions. The extra dimensions are compactified with a radius $R_c$. Thus, a fundamental mass scale, $M_D$, is related to the Planck scale by a relation $M_{Pl}^2 = M_D^{d+2} (2\pi R_c)^d$ [2].

In the next Section we consider a case of one extra dimension. The generalization to more than one extra dimension is given in Section 3. The conclusions and discussions are given in the last Section. Some technical details of our calculations are collected in Appendices.

2 One extra dimension ($d = 1$)

For the sake of simplicity and for pedagogical reasons, we will consider first one extra dimension. The general case ($d > 2$) will be analyzed in the next section. In the gravireggeon model, eikonal is given by the sum of reggeized KK gravitons in the $t$-channel [1]:

$$\chi(s, b) = \frac{1}{8\pi s} \int_{-\infty}^{0} dt J_o(b\sqrt{-t}) \sum_{n=-\infty}^{\infty} A^B(s, t, n),$$  \hspace{1cm} (1)

where $\sqrt{s}$ is an invariant energy, and the Born amplitude is of the form

$$A^B(s, t, n) = G_N [i - \cot \frac{\pi}{2} \alpha_n(t)] \alpha'_s \beta_n^2(t) \left( \frac{s}{s_0} \right)^{\alpha_n(t)}.$$  \hspace{1cm} (2)

Here $n$ is a KK-number. The value $n = 0$ corresponds to usual massless graviton.
Both massless graviton and its KK massive excitations lie on linear Regge trajectories:

$$\alpha(t_D) = \alpha(0) + \alpha'_g t_D, \quad (3)$$

where \( t_D \) denotes \( D \)-dimensional momentum transfer. Since the extra dimension is compact with the radius \( R_c \), we come to splitting of the Regge trajectory (3) into a leading vacuum trajectory,

$$\alpha_0(t) \equiv \alpha_{\text{grav}}(t) = 2 + \alpha'_g t, \quad (4)$$

and infinite sequence of secondary, “KK-charged”, gravireggeons [3]:

$$\alpha_n(t) = 2 - \frac{\alpha'_g}{R_c^2} n^2 + \alpha'_g t, \quad n \geq 1. \quad (5)$$

The string theory implies that the slope of the gravireggeon trajectory is universal for all \( s \), and \( \alpha'_g = 1/M_s^2 \), where \( M_s \) is a string scale.

In ref. [1] the imaginary part of the eikonal (1) has been calculated. In the present paper we consider the real part of the eikonal. From Eqs. (1), (2) and (5) we obtain (\( q^2_\perp = -t \)):

$$\text{Re} \chi(s,b) = G_N s \frac{\alpha'_g}{8} \int_0^\infty q_\perp dq_\perp J_0(q_\perp b) e^{-q^2_\perp R_g^2(s)}$$

$$\times \sum_{n=-\infty}^\infty \cot \left[ \frac{\pi \alpha'_g}{2} \left(-t + \frac{n^2}{R_c^2}\right) \right] e^{-n^2 R_g^2(s)/R_c^2}, \quad (6)$$

where

$$R_g(s) = \sqrt{\alpha'_g \ln(s/s_0)} \quad (7)$$

is a gravitational slope (dynamical radius). Formally, there exist poles in the sum in Eq. (6) at negative values of \( \alpha_n(t) \). It is demonstrated in Appendix A that these tachyon poles are fictitious singularities, and, thus, they will not be taken into account in our calculations.

In what follows, we will assume that \( t \) lies in the physical region, \( t < 0 \), and

$$\alpha'_g |t| \ll 1. \quad (8)$$

It is equivalent to \( |t| \ll M_s^2 \), where the string scale \( M_s \) is of order 1 TeV. The sum in (6) is effectively cut from above, \( n \lesssim n_{\max} = R_c/R_g(s) \). It means that \( \alpha'_g n^2/R_c^2 \lesssim [\ln(s/s_0)]^{-1} \ll 1 \) in (6).
Let us define $\text{Re} \tilde{\chi}(s, b)$ to be the real part of the eikonal with a pole term (corresponding to $n = 0$ in (6)) subtracted. With all mentioned above, it can be written as follows:

$$\text{Re} \tilde{\chi}(s, b) = G_N R_c^2 s \frac{1}{2\pi} \int_0^\infty q \, dq \, J_0(q \, b) \, e^{-q^2 R_g^2(s)} \times \sum_{n=1}^\infty \frac{1}{n^2 + R_c^2 |t|} \, e^{-n^2 R_g^2(s)/R_c^2}. \quad (9)$$

One can see that $\epsilon(s) = R_g(s)/R_c \ll 1$ even at ultra-high (cosmic) energies $s$. Indeed, a magnitude of $\epsilon(s)$ is defined by the ratio $\sim M_c/M_s$, with a compactification mass scale, $M_c = R_c^{-1}$, varying from $10^{-3}$ eV for $d = 2$ to $10$ MeV for $d = 6$. So, $\epsilon(s)$ is taken to be a small parameter everywhere in our calculations.

Let us consider two distinct regions of the momentum transfer $|t|$. For $0 \leq |t| \ll R_c^{-2}$, the leading term looks like

$$I_1 = \sum_{n=1}^\infty \frac{1}{n^2 + R_c^2 |t|} \, e^{-n^2 R_g^2(s)/R_c^2} \left|_{|t| R_c^2 < 1} \right. \approx \frac{\pi^2}{6} - \frac{\pi^4}{90} R_c^2 |t| + O(\epsilon(s)). \quad (10)$$

At large $|t|$ ($R_c^{-2} \ll |t| < \infty$), we will consider two subregions. If the momentum transfer runs the subregion $R_c^{-2} \ll |t| \ll R_g^{-2}(s)$, then

$$I_1 = \sum_{n=1}^\infty \frac{1}{n^2 + R_c^2 |t|} \, e^{-n^2 R_g^2(s)/R_c^2} \left|_{|t| R_c^2 \geq 1, |t| R_g^2(s) < 1} \right. \approx \frac{\pi}{2R_c \sqrt{|t|}} - \frac{1}{R_c^2 |t|} + O(\epsilon(s)). \quad (11)$$

Note, the leading terms in (10) and (11) match at $R_c \sqrt{|t|} = a_1 = 3/\pi$. At very large values of $|t|$, namely, for $R_g^{-2}(s) \lesssim |t| < \infty$, the sum in (11) has the asymptotics

$$I_1 \left|_{|t| R_g^2(s) \gg 1} \right. \approx \frac{\pi}{2R_c R_g(s) |t|}. \quad (12)$$

It can be shown that a contribution from the region $R_g^{-2}(s) \lesssim |t| < \infty$ is suppressed as compared to the region $R_c^{-2} \lesssim |t| < \infty$ by the factor $\sim \epsilon(s)$

---

1Taking into account that effectively $|\alpha_n(t) - 2| \ll 1$. 

4
(for large impact parameter which we are interested in). Thus, we can write (using table integrals from [5]):

\[ \text{Re} \bar{\chi}(s, b) \simeq G_N R_c^2 s \left[ \frac{\pi}{12} \int_0^{a_1 R_c^{-1}} q \, dq \, J_0(q b) e^{-q^2 R_g^2(s)} \right. \]

\[ + \left. \frac{1}{4 R_c} \int_{a_1 R_c^{-1}}^{\infty} dq \, J_0(q b) e^{-q^2 R_g^2(s)} \right] \simeq \frac{G_N R_c s}{4} \left\{ \frac{1}{b} J_1 \left( \frac{a_1 b}{R_c} \right) + \frac{a_1}{R_c} \right\} \times \left[ \frac{\sqrt{\pi} R_c}{2 a_1 R_g(s)} \Phi \left( \frac{1}{2}, 1; -\frac{b^2}{4 R_g^2(s)} \right) - 1 F_2 \left( \frac{1}{2}, 1; \frac{3}{2}; -\frac{a_1^2 b^2}{4 R_c^2} \right) \right] \right\}, \quad (13) \]

where \( \Phi(a; b; z) \) is the confluent hypergeometric function,\(^2\) and \( 1 F_2(a; b, c; z) \) is the generalized hypergeometric function [6]. For \( b \gg R_c^2/R_g(s) \gg R_c \), we get the following asymptotics [6]:

\[ \frac{\sqrt{\pi} R_c}{2 a_1 R_g(s)} \Phi \left( \frac{1}{2}, 1; -\frac{b^2}{4 R_g^2(s)} \right) \bigg|_{b \gg R_c} \simeq \frac{R_c}{a_1 b} \left[ 1 + O \left( \frac{R_c^2(s)}{b^2} \right) \right], \quad (14) \]

and\(^3\)

\[ 1 F_2 \left( \frac{1}{2}, 1; \frac{3}{2}; -\frac{a_1^2 b^2}{4 R_c^2} \right) \bigg|_{b \gg R_c} \simeq \frac{R_c}{a_1 b} \left[ 1 + J_1 \left( \frac{a_1 b}{R_c} \right) + \frac{R_c}{a_1 b} J_2 \left( \frac{a_1 b}{R_c} \right) \right]. \quad (15) \]

Here \( J_1(z) \) and \( J_2(z) \) are the Bessel functions. As a result, we obtain from Eqs. (13) and (14)-(15):

\[ \text{Re} \bar{\chi}(s, b) \bigg|_{b \gg R_c} \simeq -G_N s \frac{\pi}{12} \left( \frac{R_c}{b} \right)^2 J_2 \left( \frac{a_1 b}{R_c} \right), \quad (16) \]

where the constant \( a_1 \) is defined after formula (11).

At zero impact parameters, one has

\[ \text{Re} \bar{\chi}(s, b = 0) \sim G_N s \frac{R_c}{R_g(s)}. \quad (17) \]

\(^2\) The confluent hypergeometric function \( \Phi(1/2, 1; z) \) can be related to the modified Bessel function \( I_0(z/2) \).

\(^3\) The generalized hypergeometric function \( 1 F_2(1/2; 1, 3/2; -z) \) can be defined by the integral of the Bessel function \( J_0(z) \). As a result, its asymptotics has oscillations.
On the other hand, the imaginary part of the eikonal was found to be (for \( d = 1 \)) \[ \text{Im} \chi(s, b) = \sqrt{\pi} G_N s R_c R_g(s) \left[ \ln(s/s_0) \right]^{-1} \exp[-b^2/4R_g^2(s)]. \] (18)

So, the real part of the eikonal dominates the imaginary part at zero impact parameter, \( \text{Re} \tilde{\chi}(s, 0)/\text{Im} \tilde{\chi}(s, 0) \sim \ln s \), and it has a power-like behavior (with oscillations) at \( b \to \infty \) (16), while the imaginary part decreases exponentially at large \( b \).

3 More than two extra dimensions (\( d > 2 \))

The expression for the real part of the eikonal (19) is easily generalized for \( d > 2 \):

\[
\text{Re} \tilde{\chi}(s, b) = G_N s R_c^2 \frac{1}{2\pi} \int_0^\infty q_\perp dq_\perp J_0(q_\perp b) e^{-q_\perp^2/R_g^2(s)} \times \sum_{n=1}^\infty \frac{1}{n^2 + R_c^2 |t|} e^{-n^2 \varepsilon^2(s)} \sum_{n_1^2 + n_2^2 + \cdots n_{d-1}^2 \leq n^2},
\] (19)

where the notation \( n^2 = \sum_i^d n_i^2 \) is introduced. The main contribution to the sum in the RHS of Eq. (19) comes from the region \( n^2 \sim (d-2)/\varepsilon^2(s) \gg 1 \). Thus, to estimate the sum in \((n_1, n_2, \ldots n_{d-1})\) analytically, we can replace the sum by the integral:

\[
I_d = \sum_{n=1}^\infty \frac{1}{n^2 + R_c^2 |t|} e^{-n^2 \varepsilon^2(s)} \sum_{n_1^2 + n_2^2 + \cdots n_{d-1}^2 \leq n^2} \prod_{i=1}^{d-1} \int_{\mathbb{R}^2} \int dx_i
\]

\[
= \pi^{(d-1)/2} \Gamma \left( \frac{d+1}{2} \right) \sum_{n=1}^\infty \frac{n^{d-1}}{n^2 + R_c^2 |t|} e^{-n^2 \varepsilon^2(s)}. \] (20)

\(^4\)We remind that the singular term was subtracted in \( \text{Re} \tilde{\chi} \).
As in the previous section, we consider two regions of the momentum transfer. At $|t| \ll R_c^2$ we obtain (up to corrections $O(R_c^2|t|)$ and $O(\varepsilon^2(s))$):

$$I_d \simeq \sum_{n=1}^{\infty} \frac{1}{n^2} + \frac{\pi^{(d-1)/2}}{\Gamma\left(\frac{d+1}{2}\right)} \sum_{n=1}^{\infty} \frac{1}{n^2 + R_c^2|t|} (n^{d-1} - 1) e^{-n^2\varepsilon^2(s)}$$

$$\to \frac{\pi}{6} + \frac{\pi^{(d-1)/2}}{2\Gamma\left(\frac{d+1}{2}\right)} \int_1^{\infty} dz \left( z^{d/2-1} - z^{-3/2} \right) e^{-z\varepsilon^2(s)}$$

$$\simeq \frac{\pi}{6} + \frac{\pi^{(d-1)/2}}{2\Gamma\left(\frac{d+1}{2}\right)} \left[ \Psi\left(\frac{1}{2}; \frac{d}{2}, \varepsilon^2(s)\right) - \Psi\left(\frac{1}{2}; \frac{1}{2}, \varepsilon^2(s)\right) \right], \quad (21)$$

where $\Psi(a, b; z)$ is the confluent hypergeometric function, \(^5\) and we have replaced the sum in $n$ by the integral. \(^6\) For $d > 2$, Eq. (21) results in previously obtained asymptotics \((22)\). Starting from Eq. (21), we come to the asymptotics $I_1 \simeq \pi^2/6$, in accordance with Eq. \((10)\).

Now let us consider the region $R_c^{-2} \ll |t| < \infty$. Then the quantity $I_d$ can be cast in the form:

$$I_d \simeq \frac{\pi^{(d-1)/2}}{2\Gamma\left(\frac{d+1}{2}\right)} \int_1^{\infty} dz \left( \frac{z^{d/2-1}}{z + R_c^2|t|} \right) e^{-z\varepsilon^2(s)}$$

$$\simeq \frac{\pi^{(d-1)/2}}{2\Gamma\left(\frac{d+1}{2}\right)} \left[ \frac{\varepsilon^2(s)}{d} \right]^{d/2-1} \frac{\varepsilon^2(s)}{d} \left( R_c^2|t| \right)^{d/2-1} \left( \frac{1}{\varepsilon^2(s)} \right) \frac{R_c^2|t|}{d} \right] \left( \frac{1}{\varepsilon^2(s)} \right) \frac{R_c^2|t|}{d}. \quad (23)$$

For $d > 2$, we should consider separately two subregions. Namely, if the momentum transfer is bounded by inequalities $R_c^{-2} \ll |t| \ll R_g^{-2}(s)$, Eq. \((23)\) results in previously obtained asymptotics \((22)\). At very large values of $|t|$, such as $R_g^{-2}(s) \ll |t| < \infty$, one gets from \((23)\):

$$I_d \bigg|_{|t|R_g^2} \simeq \frac{\pi^{(d-1)/2}}{2\Gamma\left(\frac{d+1}{2}\right)} \left( \frac{1}{\varepsilon^2(s)} \right) \frac{1}{R_g^2|t|}. \quad (24)$$
For $d = 1$, the correct values of $I_1$ and $I_2$ are reproduced. The asymptotics match at $|t| = a^2 R_g(s)$, where

$$a^2 = (d - 2)/2.$$ (25)

Thus, we get the following expression for the eikonal:

$$\text{Re } \tilde{\chi}(s, b) \simeq G_N s \left( \frac{R_e}{R_g(s)} \right)^d \frac{\pi^{(d-3)/2}}{4 \Gamma(d+1)} \frac{\Gamma(d/2)}{\pi^{d/2-1}} \left[ I_<( \left( \frac{ab}{R_g(s)} \right) ) + I_> \left( \frac{ab}{R_g(s)} \right) \right].$$ (26)

At small impact parameter, we get immediately from (26):

$$\text{Re } \tilde{\chi}(s, b) \bigg|_{b \ll R_g(s)} = C(d) G_D s \alpha'_d \left[ \ln \left( \frac{s}{s_0} \right) \right]^{-d/2} + O \left( \frac{b^2}{R_g^2(s)} \right),$$ (27)

where $C(d)$ is a constant depending on the number of the extra dimensions, explicit form of which can be obtained from (26). The asymptotics of the real part of the eikonal at large $b$ is more complicated to analyze. For $b \gg R_g(s)$, it is calculated in the Appendix B, and the leading term looks like

$$\text{Re } \tilde{\chi}(s, b) \bigg|_{b \gg R_g(s)} \simeq -G_D s \alpha'_d \left( \frac{s}{s_0} \right) \frac{e^{-a^2} \Gamma(d/2)}{\pi^{(d+3)/2} 2^{d+1} a^2 \Gamma(d+1)} \left[ \ln \left( \frac{s}{s_0} \right) \right]^{-d/2} \times \left( \frac{R_g(s)}{b} \right)^2 J_2 \left( \frac{ab}{R_g(s)} \right).$$ (28)

The expression for the imaginary part of the eikonal for $d \geq 1$ was calculated in Ref. [11]:

$$\text{Im } \chi(s, b) = G_D s \alpha'_d \left[ \ln \left( \frac{s}{s_0} \right) \right]^{-(1+d/2)} \times \exp \left[ -\frac{b^2}{4R_g^2(s)} \right].$$ (29)
As one can see from [27] and [24],
\[
\begin{align*}
\frac{\text{Re } \tilde{\chi}(s, 0)}{\text{Im } \chi(s, 0)} & \sim \ln s. \\
\end{align*}
\]

Let us stress, we study the case when colliding particles are confined on the 4-dimensional brane, with gravity living in all $D$ dimensions. We see that the real part of the eikonal in $b$-space has a power-like behavior in $b$ with oscillations, while the imaginary part decreases exponentially at $b \gg 2\alpha_g'\ln s$. Both depend on the Regge slope $\alpha_g'$ via the gravitational radius $R_g(s)$ [7].

Let us remind the asymptotic behavior of the eikonal function derived in the framework of the string theory for the scattering of $D$-dimensional fields in a flat space-time [10]:
\[
\chi_D(s, b) \bigg|_{b^2 \gg \alpha_g' \ln s} \sim \left( \frac{b_c}{b} \right)^d + i\pi^2 \frac{G_N^D s^{\alpha'-d/2}}{(\pi \ln s)^{1+d/2}} \exp \left( - \frac{b^2}{4\alpha' \ln s} \right),
\]
where $b_c = [2\pi^{-d/2}\Gamma(d/2)G_N^D]^{1/d}$, $G_N^D$ being the Newton constant in $D$ flat dimensions. Note, the real part of $\chi_D(s, b)$ exhibits power-law falloff which does not depend on the string tension $\alpha' \equiv \alpha_g'$.

One can observe, taking into account the definition of the gravitational radius $R_g(s)$ [7], that the imaginary parts of $\chi(s, b)$ and $\chi_D(s, b)$ coincide at $b \gg \alpha_g' \ln s$. As for the real part of the eikonal, Re $\tilde{\chi}(s, b)$ decreases as a fixed (d-independent) power of $b$ at $b \to \infty$, contrary to [31]. The scales in the real parts (associated with the impact parameter $b$) are also different: dynamical radius $R_g(s)$ in our case, and $b_c \sim (G_N^D s)^{1/d}$ in $\chi_D(s, b)$ [31].

Because of the inequality $R_g(s) \ll R_c$, our formulae contain the compactification radius $R_c$ only via $D$-dimensional coupling $G_D = M_D^{(2+d)} = G_N(2\pi R_c)^d$. However, at extremely high energies, when the dynamical radius $R_g(s)$ becomes comparable with (or larger than) $R_c$, the eikonal profile in impact parameter space should “feel” the size of the compact dimensions $R_c$ [11].

In this connection, let us mention the SM in a $D$-dimensional space-time with compact extra dimensions, but without gravity [11]. In such a case, the dynamical radius, $R(s)$, is proportional to $\ln(s/s_0)/\sqrt{t_0}$, where $t_0$ denotes the nearest (non-zero) singularity in the $t$-channel (for instance, $t_0 = m_{\pi}^2$, if only strong interactions are taken into account).

\footnote{\text{It does not take place, if colliding particles live in $D$ dimensions [9].}}
The expression for four-dimensional eikonal amplitude (in the presence of \(d\) compact extra dimensions) looks like \([1]\):

\[
A(s,t) = 2is \int d^2b \ e^{iq \perp b} \left[1 - e^{i \chi(s,b)} \right].
\]

(32)

At not extreme energies, namely, for \(\sqrt{s} \lesssim M_D \sim M_s\), we have inequalities \(\text{Re} \tilde{\chi}(s,b), \text{Im} \chi(s,b) \ll 1\), and Eq. (32) is given by

\[
\tilde{A}(s,t) \simeq 4\pi s \int_0^\infty db \ J_0(q \perp b) \left[\text{Re} \tilde{\chi}(s,b) + i \text{Im} \chi(s,b) \right]\]

(33)

The imaginary part of the scattering amplitude exhibits exponential falloff at large \(|t|\):

\[
\text{Im} A(s,t) = \frac{8G_D s^2 \alpha'_g \Gamma (d/2)}{\pi^{d/2-2}} \left[\ln \left(\frac{s}{s_0}\right)\right]^{-d/2} \exp \left(t \alpha'_g \ln(s/s_0) \right).
\]

(34)

As for the real part of the amplitude, we obtain the following behavior (see Appendix C for details):

\[
\text{Re} \tilde{A}(s,t) = G_D s^2 \alpha'_g \left[\frac{\Gamma (d/2)}{2^{d/2} \pi^{d/2-1} \Gamma (d+1/2)} \left[\ln \left(\frac{s}{s_0}\right)\right]^{-d/2} \frac{\alpha'_g \ln(s/s_0)}{a^2} \left[2 + \frac{\alpha'_g \ln(s/s_0) t}{a^2} \right] + \frac{1}{t} \left[1 - \exp \left(t \alpha'_g \ln(s/s_0) \right) \right] \right]
\]

(35)

\[
\quad \times \left\{ \begin{array}{c}
\frac{1}{-t} \exp \left(t \alpha'_g \ln(s/s_0) \right) \\
\alpha'_g |t| \geq a^2/\ln(s/s_0) \\
\end{array} \right\}
\]

Note that \(\text{Im} A(s,t) \ll \text{Re} \tilde{A}(s,t)\) in the kinematical region \([3]\), in particular,

\[
\frac{\text{Re} \tilde{A}(s,t)}{\text{Im} A(s,t)} \bigg|_{t=0} \sim \ln s, \quad \frac{\text{Re} \tilde{A}(s,t)}{\text{Im} A(s,t)} \bigg|_{t \gg \alpha'_g |t| \gg (\ln s)^{-1}} \sim \frac{1}{\alpha'_g |t|}.
\]

(36)

The asymptotics of the amplitude at large \(|t|\) \([35]\) is quite different from the behavior of the eikonal amplitude in both the string theory \([10]\) and in
the model with Regge exchanges in $D$ flat dimensions [9]:

$$A(s, t) \bigg|_{|t| \gg b_c^{-2}} \sim G_N^D s^2 \alpha_g^{(1-d)/2} |t|^{-(d+2)^2/4(d+1)} e^{i \phi_D(t)},$$

(37)

where $\phi_D(t) \sim |t|^{d/2(d+1)}$, and $b_c$ is define after formula (31). Formula (35) is also different from the asymptotic behavior of $A(s, t)$ in the model with compact extra dimensions, when non-reggeized KK graviton exchanges are summed up [12]:

$$A(s, t) \bigg|_{|t| R_c^2 \gg 1} \sim G_D s^2 \alpha_g^{(1-d)/2} |t|^{-(d+2)^2/2(d+1)} e^{i \phi_D(t)}.$$

(38)

It is worth to note that (38) decreases as a power of $|t|$ (the latter being larger than $-1$ for $d \geq 1$), in spite of the fact that both amplitudes describe the scattering of fields trapped on the brane. This can be understood as follows. For non-reggeized exchanges [12], the sum in KK numbers $(n_1, n_2, \ldots, n_d)$ contains no suppression factor $\exp[-n^2 R_g^2(s)/R_c^2]$, contrary to our approach with the gravireggeo exchanges [19]. The sum diverges and needs a definition for $d > 1$. Usually, the sum is replaced by a $d$-dimensional integral, which is calculated by using dimensional regularization. This procedure leads to the power-like falloff of the eikonal with $d$-depending power, similar to the case when colliding fields are not confined to the brane, but can propagate in the extra dimensions [10]. Moreover, the eikonal is pure real in this scheme [12].

4 Conclusions

In the framework of the model with $d$ extra compact dimensions, we have calculated the quantum gravity effects related to the gravireggeo exchanges in $t$-channel. For the scattering of the SM fields living on the 4-dimensional brane, the real part of the eikonal (with the massless mode subtracted) is estimated. It is shown that it decreases as a power of $b$ (with oscillations) at large values of the impact parameter $b$. This power does not depend on the number of the extra dimensions $d$, contrary to the case when the colliding fields are allowed to propagate in the bulk. The scale, associated with the impact parameter $b$, is $\alpha_g^{-1}$, while in the $D$-dimensional flat space-time the corresponding scale is defined by $(G_N^D s)^{1/d}$, where $G_N^D$ is the Newton constant in $D$ dimensions.
The calculations complete our results on the imaginary part of the eikonal obtained previously. In particular, it was shown that the imaginary parts of the eikonal are the same for the case when colliding particles are confined to the brane and when they propagate freely in extra dimensions. In the present paper, we have also calculated the eikonal amplitude and have shown, that both the real part of the amplitude and its imaginary part decreases exponentially at large momentum transfer.

The real part of the amplitude dominates the imaginary part at zero momentum transfer, in contrast to high-energy behavior of hadronic amplitudes (see, for instance, Ref. [13]). Note, however, that this result was obtained in the region \(\ln s \ll R_c^2/\alpha'_g\). At asymptotical \(s\), the inequality \(|\text{Re} \, A(s,0)|/|\text{Im} \, A(s,0)| < \text{const}\) will be reproduced, provided the massless mode is discarded in the eikonal.

Appendix A

The Sommerfeld-Watson transformation results in the following expression for a contribution of the Regge trajectory \(\alpha(t)\) to the amplitude [4]:

\[
A(s,t)\bigg|_{\text{pole}} = -16\pi^2[2\alpha(t) + 1]\beta(t)
\times \left[ 1 + \frac{\xi \exp(-i\pi\alpha(t))}{\sin\pi\alpha(t)} P_{\alpha(t)}(-z_t(s,t)) - \frac{\xi}{\pi} Q_{\alpha(t)}(-z_t(s,t)) \right]. \tag{A.1}
\]

Here \(\xi\) is a signature of the trajectory, \(z_t(s,t)\) is a cosine of a scattering angle in the \(t\)-channel, \(\beta(t)\) is a residue of the Regge pole in a partial amplitude:

\[
A^\xi_l(t)\bigg|_{l \to \alpha} \simeq \frac{\beta(t)}{l - \alpha(t)}. \tag{A.2}
\]

We have omitted a background integral in (A.1) which is non-leading in the high energy limit \((-z_t(s,t) \gg 1\). Note that second term in the RHS of Eq. (A.1) is usually discarded, since it is also negligible at \(-z_t(s,t) \gg 1\). Nevertheless, it becomes important if we look for possible non-physical singularities.

For even signature \((\xi = +1)\), one gets the real part of the amplitude in
the form: \(^8\)

\[
\text{Re} A(s, t) \bigg|_\text{pole} = -16\pi^2 (2\alpha + 1) \beta \left[ \frac{1 + \cos \pi \alpha}{\sin \pi \alpha} P_\alpha(-z) - \frac{2}{\pi} Q_\alpha(-z) \right], \quad (A.3)
\]

where simplified notations \(\alpha \equiv \alpha(t), \beta \equiv \beta(t),\) and \(z \equiv z_t(s, t)\) are introduced. In order to analyze singularities of the amplitude in \(\alpha\), it is convenient to represent the expression in the RHS of Eq. (A.3) via hypergeometric functions \(^6\):

\[
\frac{1 + \cos \pi \alpha}{\sin \pi \alpha} P_\alpha(-z) - \frac{2}{\pi} Q_\alpha(-z) = -\pi^{-1/2} \cos \pi \alpha \left[ (-2z)^\alpha \frac{(1 + \cos \pi \alpha) \Gamma(-\alpha)}{\Gamma(-\alpha + 1/2)} \right.
\]

\[
\times \ _2F_1 \left( -\frac{\alpha}{2}, -\frac{\alpha}{2} + \frac{1}{2}; -\frac{\alpha}{2} + 1; \frac{1}{z^2} \right) - (-2z)^{-\alpha - 1} \frac{(1 - \cos \pi \alpha) \Gamma(\alpha + 1)}{\Gamma(\alpha + 3/2)}
\]

\[
\times \ _2F_1 \left( \frac{\alpha}{2} + \frac{1}{2}, \frac{\alpha}{2} + 1; \frac{\alpha}{2} + \frac{3}{2} \frac{1}{z^2} \right) \right]. \quad (A.4)
\]

This expression is symmetric under replacement \(\alpha \to -\alpha - 1\). Note that the ratio \(_2F_1(a, b; c; z)/\Gamma(c)\) has neither singularities nor zeros in \(c\).

It follows from (A.4) that the amplitude has two sets of simple poles: physical singularities at \(\alpha(t) = 2m, m = 0, 1, \ldots\), and tachyon poles at \(\alpha(t) = -(2n + 1), n = 0, 1, \ldots\). If the term \((2/\pi) Q_\alpha(-z)\) is disregarded in (A.3), the tachyon poles are shifted to the points \(\alpha(t) = -2n\). Notice, there are no poles in the RHS of (A.4) at half-integer \(\alpha\), since an expression in square brackets tends to zero and cancels zeros of a function \(\cos \pi \alpha\) at these points.

Let us demonstrate that the tachyon poles are fictitious ones. In order to do this, we will consider the Mandelstam-Sommerfeld-Watson transformation which is based on using of the Legendre function of the second kind \(^4\). By disregarding all the terms but the pole contribution and the sum in positive angular momenta, we get:

\[
A'(s, t) = 16\pi \left[ 1 + \xi \exp(i\pi \alpha(t)) \right] \left[ (2\alpha(t) + 1)\beta(t) \frac{Q_{-\alpha(t)-1}(-z_t(s, t))}{\cos \pi \alpha(t)} \right.
\]

\[
- \frac{1}{\pi} \sum_{l=1}^{\infty} (-1)^{l-1} (2l) A_{l-1/2}^\xi(t) \frac{Q_{l-1/2}(-z_t(s, t))}{\cos \pi \alpha(t)} \right]. \quad (A.5)
\]

\(^8\)Note that \(\text{Im}P_l(z) = \text{Im}Q_l(z) = 0\) at \(z > 1\), for any real \(l\) \(^6\).
In particular, the contribution of the Regge trajectory (with $\xi = +1$) into
the real part of the amplitude,

$$\text{Re}A'(s, t) \bigg|_{\text{pole}} = 16\pi(2\alpha + 1) \beta \frac{1 + \cos \pi\alpha}{\cos \pi\alpha} Q_{-\alpha-1}(-z), \quad \text{(A.6)}$$

reveals the same physical singularities (at $\alpha(t) = 2m$, $m = 0, 1\ldots$), as it can
be easily seen from the relation $^6$

$$Q_{-\alpha-1}(-z) = \frac{\pi^{1/2}(-2z)^{\alpha}}{\Gamma(-\alpha + 1/2)} \times _2F_1\left(-\frac{\alpha}{2}, -\frac{\alpha}{2} + \frac{1}{2}; -\frac{\alpha}{2} + 1; \frac{1}{z^2}\right). \quad \text{(A.7)}$$

The zeros of the function $\cos \pi\alpha$ in Eq. (A.5) can result in singularities
of $\text{Re}A'(s, t)$ at half-integer $\alpha$. However, the poles of $(\cos \pi\alpha)^{-1}$ at $
(\alpha(t) = n + 1/2$, with $n = 0, 1\ldots$, and corresponding poles of the partial amplitudes
in the sum in Eq. (A.5) cancel out. To see this, one should use the formula

$$Q_{l-1/2}(z) = Q_{-l-1/2}(z), \quad \text{(A.8)}$$

valid for any integer $l$. Only tachyon poles, $\alpha(t) = -(n+1/2), n = 0, 1\ldots$, survive. Thus, we see that positions of the tachyon poles are different if
we use Mandelstam-Sommerfeld-Watson transformation instead of standard Sommerfeld-Watson transformation. Moreover, the singularities at $\alpha(t) = -(n + 1/2)$ do not appear in the amplitude as well, if so-called Mandelstam
symmetry of the partial amplitudes with respect to the point $l = -1/2$ is assumed.$^9$

$$A_{l-1/2}^\xi(t) = A_{-l-1/2}^\xi(t). \quad \text{(A.9)}$$

All said above indicates fictitious character of the singularities at negative
values of $\alpha(t)$.

**Appendix B**

In this Appendix we will calculate the asymptotics of the RHS of Eq. (26) at
large value of variable $c = ab/R_g(s)$, where $b$ is the impact parameter, and $a$

---

$^9$From the Gribov-Froissart representation, the Mandelstam symmetry follows for all $A_{l}^\xi(t)$ with $l \geq N$, where $N$ is a number of subtractions in a dispersion relation for the amplitude, due to the symmetry property of $Q_l(z)$ $^A$. The symmetry takes place in a potential scattering (see $^4$ for more details).
is defined in the text (25). The first quantity under consideration, $I_{<}(c)$, is represented by the integral

$$I_{<}(c) = \int_{0}^{1} dz \ z J_{0}(cz) e^{-a^2 z^2}. \quad (B.1)$$

By using well-known relation between Bessel functions [7],

$$z^{\nu} J_{\nu-1}(cz) = \frac{1}{c} \frac{d}{dz} \left[ z^{\nu} J_{\nu}(cz) \right], \quad (B.2)$$

one can easily obtains from (B.1):

$$I_{<}(c) = e^{-a^2/c} \sum_{m=0}^{N} \left( \frac{2a^2}{c} \right)^m J_{m+1}(c) + \frac{2a^2}{c} J_{2}(c) \int_{0}^{1} dz \ z^{N+2} J_{N+1}(cz) e^{-a^2 z^2}$$

$$= e^{-a^2/c} \sum_{m=0}^{N} \left( \frac{2a^2}{c} \right)^m J_{m+1}(c) + o(c^{-N-2}) \quad (B.3)$$

for any integer $N \geq 0$. Thus, we obtain the leading asymptotic terms:

$$I_{<}(c)|_{c \gg 1} = e^{-a^2/c} \left[ J_{1}(c) + \frac{2a^2}{c} J_{2}(c) \right] + o(c^{-3}). \quad (B.4)$$

Note, the sum in (B.3) converges at $N \to \infty$ for any fixed $c$.

The quantity $I_{>}(c)$ is represented by the integral

$$I_{>}(c) = \int_{1}^{\infty} \frac{dz}{z} \ J_{0}(cz) e^{-a^2 z^2}. \quad (B.5)$$

In order to estimate $I_{>}(c)$ at large $c$, it is convenient to recast it in the form:

$$I_{>}(c) = \lim_{a \to 0} \left[ \int_{0}^{\infty} dz z^{\alpha-1} J_{0}(cz) e^{-a^2 z^2} - \frac{1}{0} dzz^{\alpha-1} J_{0}(cz) e^{-a^2 z^2} \right]$$

$$= \lim_{a \to 0} \left[ \int_{0}^{\infty} dz z^{\alpha-1} J_{0}(cz) e^{-a^2 z^2} - \frac{1}{0} dzz^{\alpha-1} J_{0}(cz) \right]$$

$$- \sum_{k=1}^{\infty} (-1)^k \frac{a^{2k}}{k!} \int_{0}^{1} dzz^{2k-1} J_{0}(cz). \quad (B.6)$$
By using table integrals from [5], we get (up to power corrections in $\alpha$):

$$
\int_0^\infty dz z^{\alpha-1} J_0(cz) e^{-a^2 z^2} \bigg|_{\alpha \to 0} \approx \frac{a^{-\alpha}}{2} \left[ \Gamma\left(\frac{\alpha}{2}\right) - \gamma - \ln \left(\frac{c^2}{4a^2}\right) + \text{Ei}\left(-\frac{c^2}{4a^2}\right) \right],
$$

(B.7)

where $\gamma$ is the Euler constant, and $\text{Ei}(-z)$ is the exponential integral. Analogously, one gets [4]:

$$
\int_0^1 dz z^{\alpha-1} J_0(cz) \bigg|_{\alpha \to 0} \approx \frac{1}{2} \left[ \Gamma\left(\frac{\alpha}{2}\right) - \gamma - \ln \left(\frac{c^2}{4}\right) \right] - \int_c^\infty \frac{dz}{z} J_0(z). \quad (B.8)
$$

Eqs. (B.6)-(B.8) result in the expression

$$
I_>(c) = \frac{1}{2} \text{Ei}\left(-\frac{c^2}{4a^2}\right) + \int_c^\infty \frac{dz}{z} J_0(z) - \sum_{k=1}^{\infty} \left(-1\right)^k \frac{a^{2k}}{k!} \int_0^1 dz z^{2k-1} J_0(cz). \quad (B.9)
$$

By taking into account Eq. (B.2), we get (for $N \geq 0$):

$$
\int_c^\infty \frac{dz}{z} J_0(z) = -\frac{1}{c} \sum_{m=0}^N m! \left(\frac{2}{c}\right)^m J_{m+1}(c)
$$

$$
+ 2^{N+1} (N+1)! \int_c^\infty \frac{dz}{z^{N+2}} J_{N+1}(z). \quad (B.10)
$$

A series, which arises in (B.10) in the limit $N \to \infty$, does not converge. To see this, one should use an asymptotics of the Gamma-function [6],

$$
\Gamma(m) \bigg|_{m \to \infty} \approx \exp \left[ \left( m - \frac{1}{2} \right) \ln m - m + \frac{1}{2} \ln(2\pi) \right], \quad (B.11)
$$

and an asymptotics of the Bessel function at large value of its index (at fixed $c$) [8],

$$
J_m(c) \bigg|_{m \to \infty} \approx \exp \left\{ m \left[ 1 + \ln \left(\frac{c}{2}\right) \right] - \left( m + \frac{1}{2} \right) \ln m - \frac{1}{2} \ln(2\pi) \right\}. \quad (B.12)
$$

Then one concludes that the $m$-th term in the series under consideration tends to $(2m)^{-1}$ at $m \to \infty$. So, the sum in (B.10) is an asymptotic one at large $N$. 

16
As a result, we have (for \( N \geq 0 \)):

\[
\sum_{k=1}^{\infty} (-1)^k \frac{a^{2k}}{k!} \int_0^1 dz z^{2k-1} J_0(cz) = \frac{e^{-a^2} - 1}{c} J_1(c) \\
+ \sum_{k=1}^{\infty} (-1)^k \frac{a^{2k}}{k} \left[ \frac{1}{c} \sum_{m=1}^{N} (-1)^m \frac{1}{\Gamma(k-m)} \left( \frac{2}{c} \right)^m J_{m+1}(c) \right] \\
- (-1)^N \left( \frac{2}{c} \right)^{N+1} \frac{1}{\Gamma(k-N-1)} \int_0^1 dz z^{2k-N-2} J_{N+1}(cz) \right]. \quad (B.13)
\]

Taking into account that \( 1/\Gamma(-n) = 0 \) for any non-negative integer \( n \), we come to the formula

\[
\sum_{k=1}^{\infty} (-1)^k \frac{a^{2k}}{k!} \int_0^1 dz z^{2k-1} J_0(cz) = \frac{e^{-a^2} - 1}{c} J_1(c) \\
- \frac{1}{c} \sum_{m=1}^{N} \left( \frac{2}{c} \right)^m \gamma(m + 1, a^2) J_{m+1}(c) \\
- \left( \frac{2}{c} \right)^{N+1} \frac{1}{\Gamma(k-N-1)} \int_0^1 dz z^{-N-2} \gamma(N + 2, z^2a^2) J_{N+1}(cz) \right]. \quad (B.14)
\]

Here \( \gamma(a, x) \) is the incomplete Gamma-function. At \( N \to \infty \), the sum in the RHS of Eq. (B.14) converges. It can be easily shown if we use the expansion of the incomplete Gamma-function, \( \gamma(m + 1, 1) = \sum_{k=0}^{m} \frac{1}{k!} (k + m + 1) \), and use (B.12).

It follows from Eqs. (B.9), (B.10) and (B.14) that\(^{10}\)

\[
I_>(c) = -\frac{e^{-a^2}}{c} J_1(c) \frac{1}{c} \sum_{m=1}^{N} \left( \frac{2}{c} \right)^m m! J_{m+1}(c) \\
+ \frac{1}{c} \sum_{m=1}^{\infty} \left( \frac{2}{c} \right)^m \gamma(m + 1, a^2) J_{m+1}(c) + o(c^{-N-2}), \quad (B.15)
\]

\(^{10}\)Notice, the exponetial integral \( \text{Ei}(-c^2/4a^2) \) decreases exponentially at \( c \to \infty \).
and we obtain the leading asymptotic terms:

\[ I_>(c) \bigg|_{c \gg 1} = -\frac{e^{-a^2}}{c} \left[ J_1(c) + \frac{2(1 + a^2)}{c} J_2(c) \right] + o(c^{-3}). \tag{B.16} \]

Notice that the leading terms in (B.4) and (B.16) (proportional to \( J_1(c) \)) cancel out. Thus, we get

\[ [I_(c) + I_>(c)] \bigg|_{c \gg 1} \simeq -\frac{2e^{-a^2}}{c^2} J_2(c), \tag{B.17} \]

and we arrive at the asymptotics presented in the text [28]. The complete asymptotic expansion of the functions \( I_(c) \) and \( I_>(c) \) can be obtained if desired from Eqs. (B.3) and (B.15), respectively.

### Appendix C

In order to find \( \text{Re} \tilde{A}(s, t) \), we need to calculate the integral

\[ M = \int_0^\infty db \ J_0(q^\perp b) \left[ I_(c) \left( \frac{ab}{R_g(s)} \right) + I_>(c) \left( \frac{ab}{R_g(s)} \right) \right]. \tag{C.1} \]

By taking into account formulae from the Appendix B, one can get:

\[
I_(c) + I_>(c) = -\frac{2e^{-a^2}}{c^2} J_2(c) + \left( \frac{2a^2}{c} \right)^2 \int_0^1 dz \ z^3 \ J_2(cz) \ e^{-a^2z^2} \\
+ \left( \frac{2}{c} \right)^2 \int_0^1 dz \ z^3 \ \gamma(3, z^2a^2) \ J_2(cz) \\
+ 8 \int_c^\infty \frac{dz}{z^3} \ J_2(z) + \frac{1}{2} \ \text{Ei} \left( -\frac{c^2}{4a^2} \right), \tag{C.2}
\]

where again we have defined \( c = ab/R_g(s) \).

By the use of Eq. (B.2) and other relation between the Bessel functions [7],

\[
\frac{d}{dz} \left[ z^{-\nu} J_\nu(cz) \right] = -cz^{-\nu} J_{\nu+1}(z), \tag{C.3}
\]
the following formula can be derived \((\alpha, \beta > 0)\):\(^{11}\)
\[
\int \frac{dz}{z^\mu} J_\nu(\alpha z) J_{\nu+\mu+1}(\beta z) = \frac{1}{\beta x^\mu} \sum_{m=1}^\infty \left( \frac{\beta}{\alpha} \right)^m J_{\nu+m}(\alpha x) J_{\nu+\mu+m}(\beta x) + \text{const.}
\] (C.4)

In particular, one obtains (for \(A, q_\perp > 0\)):
\[
\int_0^\infty \frac{db}{b} J_0(q_\perp b) J_2(Ab) = \frac{1}{A b} \sum_{m=1}^\infty \left( \frac{A}{q_\perp} \right)^m J_m(q_\perp b) J_{m+1}(Ab) \bigg|_{b=0}^{b=\infty} = 0.
\] (C.5)

Thus, first three terms in the RHS of Eq. (C.2) gives zero after the integration in variable \(b\) in (C.1).

The next to the last term in Eq. (C.2) results in
\[
8 \int_0^\infty db \frac{b}{J_0(q_\perp b)} J_2(Ab)
= \frac{8R_g(s)}{aq_\perp} \int_0^\infty \frac{dz}{z^2} J_2(z) J_1 \left[ \frac{R_g(s)q_\perp}{a} \right].
\] (C.6)

The integral in (C.6) is a table one (see [5]):
\[
\int_0^\infty \frac{dz}{z^2} J_2(z) J_1 \left[ \frac{R_g(s)q_\perp}{a} \right] = \left\{
\begin{array}{ll}
\frac{R_g(s)q_\perp}{8a} \left[ 2 - \frac{R_g^2(s)q_\perp^2}{a^2} \right], & \text{for } |t| < a^2R_g^{-2}(s) \\
\frac{a}{8R_g(s)q_\perp}, & \text{for } |t| \geq a^2R_g^{-2}(s).
\end{array}
\right.
\] (C.7)

The contribution from the last term in Eq. (C.2) can be also explicitly calculated with the help of a table integral from [5]:
\[
\frac{1}{2} \int_0^\infty db \frac{b}{J_0(q_\perp b)} \text{Ei}\left( -\frac{c^2}{4a^2} \right) = -\frac{1}{q_\perp^2} \left[ 1 - e^{-q_\perp^2}R_g^2(s) \right],
\] (C.8)

\(^{11}\)A special case of this equation for \(\mu = 0\) and \(a = b\) can be found in [5].
and we get:

\[
M \left|_{q_{\perp} < aR_g^{-1}(s)} \right| = \frac{R_g^2(s)}{a^2} \left[ 2 - \frac{R_g^2(s)}{a^2} q_{\perp}^2 \right] - \frac{1}{q_{\perp}^2} \left[ 1 - e^{-q_{\perp}^2 R_g^2(s)} \right],
\]

\[
M \left|_{q_{\perp} \geq aR_g^{-1}(s)} \right| = \frac{1}{q_{\perp}^2} e^{-q_{\perp}^2 R_g^2(s)}. \quad (C.9)
\]

As a result, we arrive at the expression for the amplitude presented in the text (35).
