Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
Short Communication

Emergence of B.1.1.318 SARS-CoV-2 viral lineage and high incidence of alpha B.1.1.7 variant of concern in the Republic of Gabon

A B S T R A C T

Objective: Variants of concern (VOCs) associated with relatively high transmissibility appear to be rapidly spreading in Gabon. Therefore, it is imperative to understand the distribution of several VOCs in the population, which could have implications for transmissibility and vaccine efficacy.

Methods: Between February and May 2021, SARS-CoV-2 genomes were sequenced using the Oxford nanopore MinION method and the respective genome diversity was elucidated. Phylogenetic analysis was performed and genomes were classified using pangolin lineages.

Results: The results highlighted an increase (46%) in the alpha VOC (B.1.1.7) in the Gabonese population over the study period. In addition, an increase (31%) in the B.1.1.318 lineage, which is associated with high transmission and impaired vaccine efficacy (D614G+E484K+Y144del), was detected.

Conclusion: With the second wave ongoing, these findings highlight the need for surveillance of the SARS-CoV-2 genome in the Republic of Gabon and should provide useful guidance to policymakers in selecting an appropriate vaccine for this population.

Introduction

SARS-CoV-2 variants of concern (VOC) appear to spread more easily. Other emerging variants are also gaining attention, either known as a “variants of interest” (VOI) or “variants under investigation” (VUI), which increase transmission, warranting further studies. Since the onset of the COVID-19 pandemic, the SARS-CoV-2 genomes have accumulated genetic diversity, leading to increased transmission with altered viral properties (Kraemer et al. 2021).

Of the several new SARS-CoV-2 variants recently reported, alpha VOC B.1.1.7 (associated with the N501Y mutation)
(Rambaut et al. 2020), beta VOC B.1.351 (associated with the E484K mutation) (Tegally et al. 2021), and gamma VOC P1 (B.1.1529, with mutations likely epidemiological significance E484K, K417T, and N501Y) (Graif et al. 2021), and the delta VOC B.1.617.2 (mutations with likely epidemiological significance P681R, K417N, and L452R) are of great interest. B.1.318 has recently been reported as a VOI, carrying D614G, D614H, E484K, P681H, T95I, Y144del, among which D614G has been implicated in increased transmissibility, and E484K with decreased vaccine efficacy. The Republic of Gabon has evidence of a circulating alpha VOC B.1.1.7 (Zoa-Assoumou et al. 2021) and has thus far recorded 25,819 confirmed cases with 165 deaths until 30 August 2021 (WHO 2021). This may be due to factors such as age, demographical, and the constant exposure and burden of co-infections (e.g. with helminths) (Velana et al. 2021). The current second wave, which has been ongoing since February 2021, has led to increased SARS-CoV2 genomic surveillance. This study aimed to reveal the actual distribution of SARS-CoV-2 variants circulating in the country.

Materials and Methods

The Centre de Recherches Médicales de Lambaréné undertook COVID-19 surveillance between February and May 2021. The study participants were residents living in the Lambaréné region.

NGS sequencing and phylogenetic analysis

Samples with confirmed Ct values ≤30 were subsequently sequenced using the MinION sequencing platform (Oxford Nanopore Technologies, Oxford, UK). Libraries were prepared according to the nCoV-2019 sequencing protocol (RAPID barcoding, 1200 bp amplicon) V3 (Freed et al. 2021). Viral genome assembly was performed using the ARTIC pipeline (https://github.com/artic-network/fieldbioinformatics).

SARS-CoV-2 genomes (n=74) circulating between February and May 2021 were retrieved from the global database for influenza gene sequences (GISAID) for African (n=15) and European (n=14) lineages. Only complete viral genomes were included in the analysis, and different previously represented lineages (n=27) from 29 countries were included. All 74 genomes in the present study were aligned with Wuhan-Hu-1 strain (NC_045512.2) using the Multiple Alignment using Fast Fourier Transform (MAFFT) algorithm (Katoh et al. 2002). The phylogenetic tree was reconstructed with the maximum likelihood method with 1000 bootstrap iteration using the general time-reversible (GTR) model with rate heterogeneity (GTR+G) in the IQ-TREE server (Trifinopoulos et al. 2016). SARS-CoV-2 genomes were classified into lineages using Phylogenetic Assignment of Named Global Outbreak LiNEages (pangolin) (O'Toole et al. 2021) and viral clades by Nextclade Beta (https://clades.nextstrain.org/). The final dataset was displayed with FigTree v1.4.4.

Results

The sequenced SARS-CoV-2 genomes and their respective genome diversity with distinct viral lineages are summarized in Table 1, and the sequences were submitted to the GISAID database. Of the 71 SARS-CoV-2 genomes, the alpha VOC B.1.1.7 lineage (46%) was predominant, followed by B.1.1.318 (31%), B.1 (7%), S.1, B.1.214.2 and B.1.620 (3%, respectively), and beta VOC B.1.351 (1%), B.1.400, B.1.525, B.1.619 and B.1.1 (1%, respectively). The identified alpha VOCS clustered into two GISAID clades GR (n=7/33) and GRY (n=26/33), whereas others clustered to either of the GISAID clades G, GH and GR. The proportion of B.1.1.318 increased systematically from 11% (3/27) in March, followed by 37% (7/19) in April to 75% (12/16) in May, and the B.1.1.318 genomes were representative of GISAID clades GR. Phylogenetic analysis showed that 71 SARS-CoV-2 genomes from Gabon sequenced into 10 groups, each representing a distinct SARS-CoV-2 lineage (Figure 1). The B.1.1.318 lineage was polyphyletic, as the cluster had sequences from Europe and parts of Africa. The B.1.1.7 lineage was paraphyletic, as the majority of the sequences from Gabon were grouped into a distinct sister clade. Among the other sequences, B.1.214.2, B.1.620, B.1.619 and B.1.525 formed monophyletic groups. Of the rest, two solitary sequences represented by B.1.351 did not cluster, and the solitary B.1.1.7 sequence was paraphyletic to B.1.1.318 lineage (Figure 1).

Discussion

The observation of an increase in incidence of B.1.1.318 from 11% to 75% between March and May 2021 is of interest.Variant B.1.1.318 was discovered in January 2021. Phylogenetic analysis (Figure 1) revealed that all 33 isolates in the B.1.1.7 clade formed a distinct cluster. On the other hand, 22 isolates fell into two relatively cohesive phylogenetic clusters of B.1.1.318 genomes, with the first ancestral to the second, suggesting two distinct genetic divergences, the first due to early introduction by imported cases and subsequently evolving within Africa. Similarly, the SARS-CoV-2 genomes from clades B.1.214.2, B.1.351, B.1.525, B.1.19 and B.1.620 suggest that they could be recent introductions to the Gabonese and are therefore less abundant. Taken together, this study highlights circulating new variants of potential epidemiological importance.
Conflicts of interest

The authors declare no conflict of interest in the submitted work.

Acknowledgments

We thank all researchers and staff of CERMEL who are working for COVID-19 diagnosis. The authors gratefully acknowledge the encouragement of the Gabonese Government. We also thank the COPIL committee and the Ministry of Health. The authors TPV and AAA thank the support of PANDORA-ID NET. AAA and MGP are members of CANTAM (EDCTP-RegNet2015-1045)

Author’s contribution

AAA and BL designed the study procedures. GPM performed all experimental procedures. MNM, RB, SOOB, GNO, JYH, SZA, EGR, and RMN were involved in sampling procedures and collating the meta data. SRP and SR supported experimental procedures and performed phylogenetic analysis. JBLD, JFDS, SB, BL, and PGK contributed to the study design and patient recruitment. AAA, GPM and TPV analysed the data and wrote the manuscript.

Data availability statement

The data supporting reported results are available on request.

Funding

AIDCO: mobilization of research funds for Covid-19 as a public health emergency EDCTP RIA 2020 EF-2961.

Ethical Statement

Informed consent was obtained from all subjects involved in the study.
