Factors associated with incomplete immunisation in children aged 12–23 months at subnational level, Nigeria: a cross-sectional study

Paul Eze, Ujunwa Justina Agu, Chioma Lynda Aniebo, Sergius Alex Agu, Lucky Osaheni Lawani, Yubraj Acharya

ABSTRACT

Objectives National immunisation coverage rate masks subnational immunisation coverage gaps at the state and local district levels. The objective of the current study was to determine the sociodemographic factors associated with incomplete immunisation in children at a sub-national level.

Design Cross-sectional study using the WHO sampling method (2018 Reference Manual).

Setting Fifty randomly selected clusters (wards) in four districts (two urban and two rural) in Enugu state, Nigeria.

Participants 1254 mothers of children aged 12–23 months in July 2020.

Primary and secondary outcome measures Fully immunised children and not fully immunised children.

Results Full immunisation coverage (FIC) rate in Enugu state was 78.9% (95% CI 76.5% to 81.1%). However, stark difference exists in FIC rate in urban versus rural districts. Only 55.5% of children in rural communities are fully immunised compared with 94.5% in urban communities. Significant factors associated with incomplete immunisation are: children of single mothers (aOR=5.74, 95% CI 1.45 to 22.76), children delivered without skilled birth attendant present (aOR=1.93, 95% CI 1.24 to 2.99), children of mothers who did not receive postnatal care (aOR=6.53, 95% CI 4.17 to 10.22), children of mothers with poor knowledge of routine immunisation (aOR=1.76, 95% CI 1.09 to 2.87), dwelling in rural district (aOR=7.49, 95% CI 4.84 to 11.59), low-income families (aOR=1.56, 95% CI 1.17 to 2.81) and living further than 30 min from the nearest vaccination facility (aOR=2.15, 95% CI 1.31 to 3.52).

Conclusions Although the proportion of fully immunised children in Enugu state is low, it is significantly lower in rural districts. Study findings suggest the need for innovative solutions to improve geographical accessibility and reinforce the importance of reporting vaccination coverage at local district level to identify districts for more targeted interventions.

INTRODUCTION

Immunisation, defined as the process that makes a person immune or resistant to an infectious disease, typically by the administration of a vaccine, is one of the most effective interventions in contemporary public health practice. Several cost-benefits analyses have consistently placed immunisation as one of the most cost-effective health interventions with huge direct and societal benefits. Immunisation saves about 2–3 million lives every year, and has successfully led to the elimination of a number of vaccine-preventable diseases in some high-income countries, including polio, diphtheria and pertussis. Indeed, childhood immunisation has had a remarkable impact on child morbidity and mortality worldwide with immense positive multiplier effects on the larger communities.

Nigeria is one of the 10 countries (Angola, Brazil, the Democratic Republic of the Congo, Ethiopia, India, Indonesia, Mexico, Nigeria, Pakistan and the Philippines) that account for over 60% of the children who did not get DPT3 in 2019. DTP3 coverage is an indicator of how well countries are providing routine immunisation (RI) services. In 2017, about
20% of the world’s infants with incomplete DPT immunisation lived in Nigeria. Three million of the estimated 8.9 million infants in the WHO African Region who did not receive any measles containing vaccine in 2015 live in Nigeria. Hence, Nigeria accounts for nearly 40% of the 28,279 confirmed measles cases reported from the WHO African Region in 2016.

The Expanded Programme on Immunization in Nigeria, created in 1979, had a significant impact during the first few years with immunisation coverage peaking at 81.5% in 1990. Immunisation coverage plummeted to 12.3% in 2003 due to a myriad of factors including low government commitment to Expanded Programme on Immunization (EPI) policy, over-centralisation in the administration of EPI at the federal level, collapse of the primary healthcare service on which EPI services were delivered, and vaccination refusal mostly due to religious beliefs in the northern part of the country. Several strategies were deployed in subsequent years to address the low immunisation coverage, including RI strengthening, supplemental immunisation activities, global positioning system tracker and several community-level interventions. Despite these efforts, preliminary results of the 2019 National Nutrition and Health Survey suggests a national DPT3 coverage of 67%. However, even the low national immunisation coverage rates mask subnational immunisation coverage gaps at the state and local district levels. For example, immunisation coverage ranged from 5% to 48% across states in northern Nigeria in the 2018 National Demographic and Health Survey (DHS).

The Immunization Agenda 2030 (IA2030) is a global strategy led by the WHO to ensure every child is protected by full immunisation, regardless of location, age, socio-economic status or gender-related barriers by 2030. Despite overall improvements in immunisation coverage at the national level, geographic variations in the immunisation coverage persists at most subnational and district levels. Achieving geographical parity, however, depends on capturing and understanding local patterns of coverage required to provide optimal, child-focused vaccine delivery services. Also, while nationally representative surveys such as the DHS and Multiple Indicator Cluster Survey have a standardised data collection procedures across countries that is also consistent over time, presenting immunisation coverage at national levels fails to capture the all-important local patterns of coverage required to properly fine-tune vaccine delivery services. Furthermore, relying on subnational administrative data for assessing immunisation system performance and tracking progress is often fraught with limitations such as missing data and poor data quality.

This study seeks to identify the factors associated with incomplete immunisation at the subnational level using Enugu state as point of focus. Enugu state has a high number of unimmunised children and has the lowest proportion of children with complete immunisation in the southeast region. Hence, employing the WHO multi-stage sampling methods for community survey, this study aims to identify the sociodemographic factors associated with incomplete immunisation in children aged 12–23 months at a subnational and local level. Our findings could help tailor strategies and operational plans to address immunisation gaps and reach children in every district with life-saving vaccines.

### METHODS

This was a community-based cross-sectional survey of mothers of children 12–23 months old residing in Enugu state in July 2020. The study considered all children 12–23 months old eligible for sampling, and used the Strengthening the Reporting of Observational Studies in Epidemiology guidelines to ensure appropriate reporting of its study’s design, conduct and findings.

### Study setting

Nigeria is the most populous country in Africa and the sixth most populous in the world. She is located in Western Africa and is divided into six geopolitical regions: northeast, northwest, northcentral, southsouth, southeast and southwest. She has 36 states—the second administrative division, and a federal capital territory in Abuja. Each state is further divided into smaller administrative units called local government areas (LGAs) and each LGA is further divided into wards.

Enugu state is one of the 36 states in Nigeria and one of the five states that make up the southeast geopolitical region in the country. Enugu state is further divided into 17 LGAs, four of which are predominantly urban (Enugu East, Enugu North, Enugu South and Nsukka) and the rest are predominantly rural. Enugu state’s 2020 projected population is 4,769,916, with most of the population living in urban centres in Enugu and Nsukka.

### Sample size

Using steps described in the WHO Vaccination Coverage Cluster Surveys Reference Manual 2019, we determined the sample size using immunisation coverage of 36.0% obtained for Enugu state in the most recent 2018 Nigeria DHS, significance level of 5.0%, precision of 5.0%, design effect of 2.5 and an inflation of 15% (to account for non-response). The calculated minimum sample size was 1,183 which we increased to 1,250 to boost the power of the study.

### Sampling procedure

We used a three-stage sampling technique. In the first stage, we used a simple random sampling technique by balloting to select four LGAs: two each from the urban and rural areas of the state. In the second stage, we randomly selected (by balloting) a total of 50 clusters based on probability-proportional-to-population: 15 clusters from Enugu East LGA, 15 clusters from Enugu North LGA and 10 clusters each from Ezeagu LGA and Udenu LGA. In the third stage, we selected 25 households in each cluster.
each of the 50 clusters (ward). In each cluster, we selected the first household randomly and subsequent households contiguously in the right direction until we achieved the required number of households for that cluster. From each selected household, we selected one eligible child. If a selected household had more than one eligible child, we selected the youngest child older than 12 months. If a selected household had no eligible child, we visited the next contiguous household, and selected one eligible child.

Data collection
A team of 14 trained community health workers collected the data using structured pretested interviewer-administered questionnaires. We constructed the questionnaire from a review of the available literature on immunisation surveys in similar contexts, and tested it for acceptability and logical structure in a sample of 20 mothers before the study. Prior to the survey, we trained the team on the study’s objectives, interpreting and extracting data from health cards/vaccination certificates, sampling techniques, walking distance estimation using Google Maps mobile app, ethical issues including the process of taking informed verbal consent and administration of the questionnaire. We administered the questionnaire in Igbo (the local language) except for a few non-Igbo speakers whom we administered the questionnaire in English. The research team directed the questions to the mothers and recorded only their responses.

Data we collected include sociodemographic characteristics of mothers and children including maternal healthcare (MHC) utilisation (antenatal care (ANC), skilled birth attendant (SBA) present at birth and post-natal care (PNC)), knowledge of mothers regarding RI, immunisation status of children and reasons for any non-vaccination. If the immunisation card was available, we recorded immunisation information of each inoculation the child received. If a child had never received an immunisation card or the mother was unable to present the immunisation card to the interviewer, the immunisation data/information for the child was based on the mother’s report.

We used Google Map mobile app on smartphones to estimate the walking distance from each study participant’s house to the nearest vaccination centre in all but four clusters (in Ezeagu LGA). In these four clusters, we first identified the nearest routine childhood vaccination point in each cluster and then estimated the walking distance from this nearest vaccination facility to each household included in the study. To evaluate mothers’ knowledge of RI and vaccine-preventable diseases, the interviewers asked questions on the correct purpose of immunisation, different vaccine-preventable diseases, the correct age for receiving the vaccines and the total number of visits required to complete the recommended vaccination for the child. We evaluated the responses as per the National Primary Healthcare Development Agency RI schedule. We coded correct responses as 2 points, incorrect responses 1 point, ‘I do not know’ 0 (zero) point.

Outcome variable
We categorised children as fully immunised, partially immunised or unimmunised (zero-dose) based on the types and doses of antigens received. We defined a ‘fully immunised child’ as a child who had received one dose of BCG, three doses of polio vaccine (excluding Oral Polio Vaccine (OPV) given at birth), three doses of pentavalent vaccine and one dose of measles vaccine by 12 months of age. Likewise, we defined a partially immunised child as a child who missed at least any one of the above doses, and an ‘un-immunised’ or ‘zero-dose’ child as a child who had not received any vaccine by 12 months of age. Incomplete immunisation, in this study, includes partially immunised children and unimmunised (zero-dose) children. Immunisation status was based on mothers’ recall and immunisation card record (ie, where the mother
presents an immunisation card, the child's immunisation status is based on records in the card, but where an immunisation card is not available, the immunisation status is based on mothers' recall) as recommended by the WHO.26 A number of other studies have used this method,32 37 which has proven to be a reliable assessment of immunisation coverage.38–40 We did not include vitamin A and yellow fever vaccines in determining complete immunisation status for this study.

**Data analysis**

We entered the data into Microsoft Excel (Microsoft, Redmond, Washington, DC, USA), cleaned and transferred to IBM SPSS V.27.0 (IBM, Armonk, New York, USA) for statistical analyses. We used frequency and percentage to describe the data, and χ² test to test for statistical significance. We used t-test to assess for statistical difference in the mean scores for knowledge of RI. We conducted multivariate logistics regression analyses to estimate adjusted ORs with 95% CI while adjusting for mothers age, marital status, mothers educational status, mothers occupation, religion, ethnic/tribal group, family monthly income, sex of the index child and source of information on immunisation. We dichotomised aggregate scores for questions on awareness of RI into satisfactory knowledge (10 points and above) and poor knowledge (less than 10 points) prior to inclusion in the regression model. We used p<0.05 to define statistical significance, and all tests were two-tailed.

**Patient and public involvement**

No patients nor the public were involved in developing the research question and study design or in the implementation of the study design, the interpretation of the results and writing of the manuscript. There are no plans to share the study with patients, will share with the public through open access publishing.

**RESULTS**

**Sociodemographic characteristics of mothers and children**

We interviewed 1254 distinct mothers with mean (SD) age of 28.7 (4.3) years. Forty-eight per cent of mothers were aged 20–29 years old, about 89.9% were married, 93.9% had at least secondary education or higher and about three-quarters (75.5%) were employed. The mean (SD) age of the children was 16.8 (3.3) months, the age ranged from 12 to 23 months and about half (51.0%) were girls (table 1).

### Table 1  Sociodemographic characteristics of mother and children in Enugu state, Nigeria, July 2020

| Sociodemographic characteristics | Frequency (N=1254) | Proportion (%) |
|----------------------------------|--------------------|---------------|
| Mothers' age                     |                    |               |
| <20 years                        | 54                 | 4.3           |
| 20–29 years                      | 602                | 48.0          |
| ≥30 years                        | 598                | 47.7          |
| Marital status                   |                    |               |
| Single                           | 50                 | 4.0           |
| Currently married                | 1127               | 89.9          |
| Divorced/widowed                 | 77                 | 7.1           |
| Mothers' education               |                    |               |
| Primary or lower                 | 77                 | 6.1           |
| Secondary or higher              | 1177               | 93.9          |
| Mothers' working status          |                    |               |
| Stay-at-home/housewife           | 307                | 24.5          |

Continued
rate, which is pentavalent-3 coverage rate in this study, was 83.9% (95% CI 81.7% to 85.9%).

Immunisation coverage rates differed based on the rurality–urbanity of communities in the state. FIC rate was 94.5% (95% CI 92.7% to 96.1%) in urban communities and 55.5% (95% CI 51.0% to 59.9%) in rural communities. In both urban and rural communities, the proportion of children vaccinated with antigens given at birth and 6 weeks of age were more than the proportions of children vaccinated with antigens given at later ages. Of the 1254 children, 578 possessed immunisation cards, indicating an immunisation card retention rate of 48.7% (95% CI 45.9% to 51.6%). About two-fifths of unvaccinated (zero-dose) children were not vaccinated because vaccination sites were too far while another two-fifths reported absence of vaccines in the health facility (online supplemental file 1).

**Factors associated with immunisation status**

Table 3 shows results from a bivariate analysis of MHC utilisation history and knowledge of RI. Use of SBA during delivery of index child, and receipt of postnatal care (at least one postnatal visit) were statistically significant factors associated with incomplete immunisation. Insufficient knowledge of RI was also statistically significantly associated with incomplete immunisation.

Multivariate logistic regression model was statistically significant, $\chi^2(25)=24.217$, $p=0.002$. The model explained 57.0% (Nagelkerke $R^2$) of the variance in immunisation status and correctly classified 90.7% of cases. Single mothers (aOR=5.74, 95% CI 1.45 to 22.76), mothers who delivered without SBA (aOR=1.93, 95% CI 1.24 to 2.99), mothers who did not receive any postnatal care (aOR=6.53, 95% CI 4.17 to 10.22) and mothers with poor knowledge of RI (aOR=1.76, 95% CI 1.09 to 2.87) were significant factors associated with incomplete immunisation (table 4). Community level factors associated

with incomplete immunisation were rural community (aOR=7.49, 95% CI 4.84 to 11.59), low-income households (aOR=1.56, 95% CI 1.17 to 2.81), and living further than 30 min walking distance from the nearest vaccination facility (aOR=2.15, 95% CI 1.31 to 3.52).

**DISCUSSION**
This study evaluated immunisation coverage data in urban and rural areas of Enugu state and offers a close-up assessment of sociodemographic factors associated with incomplete immunisation at the subnational and local
level. There are four main findings from this study. First, this assessment of immunisation coverage of children aged 12–23 months in 50 randomly selected wards in rural and urban districts (LGA) in Enugu state found that the FIC rate in Enugu state to be low, below the Reaching Every District (RED’s) subnational target of 80% immunisation coverage. About one in five (21.1%) children aged 12–23 months in the state were not fully immunised. This suggests that even after almost two decades of implementing the RED strategy in Nigeria, some states in the southern region with purportedly high immunisation coverage did not yet meet the (RED’s) subnational immunisation target. This partially explains why huge investments in immunisation activities have had minimal impact on the incidence of vaccine preventable diseases in Enugu state.

The FIC rate in this study is higher than FIC rates reported in other subregions in Nigeria, and Ethiopia, and lower than FIC rates reported in Cameroon and Ghana. The FIC rate is also substantially higher than the FIC rate reported for Enugu state (36.4%) in the latest (2018) Nigeria DHS. There are three possible reasons for this difference. The first reason relates to the definition of FIC: FIC was defined for DHS as having received one dose of BCG, one dose of measles, three doses of DPT and three doses of OPV vaccines. For this study, we used our definition as in DHS, but for OPV, we defined as three doses of polio vaccine instead, that is, three doses of polio vaccine, IPV, in line with the Polio Endgame Strategy 2019–2023. To illustrate how the difference in FIC definition drives the overall rates, we calculated FIC by applying our definition to the DHS data which shows that FIC rates in the current study and DHS are within 11 percentage points when our definition of FIC is used (online supplemental file 2). Additionally, difference in the sampling approaches used in our study and DHS, and the resulting differences in the characteristics of the sample could explain some of the difference. A comparison of demographic characteristics of our sample with that of the DHS sample (in Enugu state) shows that mothers in our sample are more educated and more likely to be working (online supplemental file 3). It is reasonable to expect a higher FIC among these mothers. Strikingly, children in our sample are of lower birth order than in the DHS and disproportionately from rural area. It appears that higher vaccination rates among younger more educated and working mothers is less than offset by lower vaccination rate among children of lower birth order and those from rural areas. Finally, a portion of the difference could be due to the State Government’s recent efforts to boost vaccination coverage in the state since the 2018 Nigeria DHS.

Second, further analysis based on rurality of residence reveals stark disparity in the FIC rate between urban communities and rural communities. Urban communities had a substantially higher FIC rate (94.5%) than rural communities (55.5%). This observation is consistent with findings in other subregions in Nigeria, and Ethiopia, but differs with findings in Bayelsa State, Nigeria where immunisation coverage was higher in the rural community than in the urban community. Our data show that almost half of infants in rural communities miss out on at least one of the critical life-saving BCG, Pentavalent, Polio and Measles vaccines. This finding underscores the importance of monitoring data at subdistrict levels to identify vaccination gaps and tailor operational strategies accordingly.

Third, the low DPT-3 coverage in rural communities (63.0%) points to gaps in RI delivery in those communities and is consistent with a study conducted in another rural community in Enugu. Furthermore, the immunisation dropout rate in both urban and rural communities is low, below the 10% cut-off recommended by WHO. The low immunisation dropout rate (<10.0%) and the low DPT-1 coverage in rural communities (78.5%) together suggests that access to RI services in these contexts remains a problem, as a previous study have suggested. There are many factors responsible for the rural–urban differences in access. For example, vaccination points are more geographically accessible to families in urban communities than in rural communities. Rural communities incur higher travel costs to reach vaccination points and rural communities are less aware of the importance of immunisation. Finally, marital status, MHC utilisation, poor knowledge of RI, poor family income and geographical accessibility were associated with incomplete immunisation at the district level. Children of single mothers are less likely to be fully immunised compared with married mothers. Married mothers are more financially stable and most likely to discuss the health needs of their children, including immunisation. Also, stigma, psychological trauma and hardship associated with single motherhood in these contexts negatively impacts access to health and vaccination. MHC utilisation also significantly predicts incomplete immunisation. Mothers who give birth using SBA are more likely to have them fully immunised than mothers who did not use SBA. Likewise, mothers who receive PNC care are more likely to have their children fully immunised. This is consistent with several studies in other low-income and middle-income countries (LMICs) that demonstrate that increased health communications on immunisation during MHC utilisation was significantly associated with childhood immunisation. However, given that the sequence of MHC utilisation is ANC-SBA-PNC, the absence of a significant effect for ANC in this study does not imply that adequate ANC attendance is not associated with RI. Instead, our data suggest that other factors such as accessibility to health facilities could have a stronger association with RI than adequately attending ANC.

**Strengths and limitations**

Our study extends the body of knowledge on immunisation uptake in rural areas vis-à-vis urban areas at the
subnational level, our results can be generalised to similar contexts in Nigeria and beyond and provides important evidence to policymakers and programme managers for improving immunisation coverage. However, our study is not without limitations. First, health system factors including vaccine availability, healthcare personnel and logistics, which are known to influence uptake of immunisation coverage were not adequately explored. Also, paternal factors that may influence the completion of immunisation were not evaluated. However, the primary goal of this study was not to assess the effect of these factors. Second, new vaccines recently introduced into the Nigeria RI schedule (specifically, Rotavirus vaccine and Pneumococcal conjugate vaccine) were not explored. Third, although maternal recall has been shown to be a reliable estimate of maternal recall in Senegal, Ethiopia and Tanzania, there is little evidence that it is a reliable coverage measure in Nigeria. A similar study in Osun state showed that agreement between the mothers’ recall and immunisation card assessment was low. This (maternal recall) could have also biased our estimates. Finally, pockets of hard-to-reach Fulani settlements that have been shown to have poor immunisation coverage were not included in our sample. Due to the deteriorating security situation in the country and the absence of security assurances, we could not send data collectors to these settlements.

**Policy implications**

Our study findings have policy implications for vaccination delivery in LMICs attempting to improve national and subnational immunisation coverage. Innovative solutions to improve geographical accessibility are undoubtedly needed to achieve IA2030 targets at local levels. Also, our study found that mothers who used MHC services were significantly more likely to have full immunised children suggesting that improving MHC utilisation, especially in underserved rural communities, might be an effective strategy in achieving the IA2030 national and subnational targets. However, further studies, preferably randomised controlled trials, are needed to confirm if strategies aimed at improving MHC utilisation actually improve immunisation rate. Finally, our study demonstrates the importance of reporting vaccination coverage at the local/district level to draw attention to regional inequities at that level and identify regions/districts for more targeted interventions.

**CONCLUSIONS**

The FIC rate in rural communities in Enugu state is below the RED target of 80% for all antigens by 2020. About one in two children in rural communities in Enugu state is not fully immunised. Sociodemographic factors associated with full immunisation at the subnational level are single motherhood, MHC utilisation, family income, rural residence and geographical proximity to health facilities.

Study Interview guide

Factors associated with incomplete immunization in children aged 12 to 23 months at sub-national level, Nigeria – a cross-sectional study

**INSTRUCTIONS**
1. Seek permission from the mother to participate before you commence. If mother is < 18 years old, seek permission of the husband (if mother is < 18 years old and married) or mother’s mother/father (if mother is < 18 years old and single)
2. If more than two children in the age bracket, only interview for the youngest child more than 12 months of age
3. Always be polite and courteous throughout the interview. NEVER Shout. NEVER Criticize.
4. Please complete ONE questionnaire for one/each child

Section A: Sociodemographic Data

1. Local Government Area: ________________________________

2. Cluster or Ward: ________________________________

3. Mother’s age
   a. < 20 yrs
   b. 20 – 24 yrs
   c. 25 – 29 yrs
   d. 30 – 34 yrs
   e. ≥ 35 yrs

4. Marital status
   a. Single
   b. Married
   c. Divorced
   d. Widow

5. Mother’s education
   a. None
   b. Primary
   c. Secondary
   d. Tertiary

6. Mother’s Occupation
   a. Stay-at-home/Housewife
   b. Farmer
   c. Civil Servant
   d. Trader
   e. Artisan

7. Tribe/Ethnicity
   a. Igbo
   b. Hausa/Fulani
c. Yoruba
   d. Igala
   e. Others

8. Family religion
   a. Christian
   b. Islam/Muslim
   c. African Traditional Religion

9. Family monthly income
   a. < N 40,000
   b. N40,000 to N79,999
   c. N80,000 to N119,999
   d. ≥ N120,000

10. Sex of child
    a. Female/Girl
    b. Male/Boy

11. Birth order in the family
    a. First born
    b. Second or third born
    c. Others

Section B: Prevalence & Determinants

1. Has your child been vaccinated?
   A. YES
   B. NO

   >> If YES to Q1 above, when was your child vaccinated?
   A. At the appropriate age
   B. Later than appropriate date

2. Please where is the Immunization card? Is the mother able to provide the card?
   A. YES
   B. NO

   >> If mother is NOT able to provide the card, Why?
   A. Mother cannot find it during interview
   B. Mother lost card before interview, i.e. could not find the card before the day of interview
   C. Mother was not given any immunization card at health centre

3. How many antenatal care visits did you attend while pregnant for this child?
   A. None, I did not attend any antenatal clinic
   B. Only one visit
   C. Two visits
   D. Three visits
   E. Four visits or more
4. How many TT injections did you receive during pregnancy?
   A. None, I did not receive any TT injection
   B. One injection
   C. Two or more injections

12. Where did you deliver this child?
   A. In a hospital
   B. With Traditional birth attendants (TBA)
   C. At home

5. Did you attend any post-natal care consultation after delivering this child?
   A. YES
   B. NO

6. Where did you hear of vaccination? (Please tick all that apply)
   A. Hospital/Health facility
   B. Family/friends
   C. Church/Mosque
   D. TV
   E. Radio
   F. Social media (Facebook, Twitter, WhatsApp, Instagram)

7. What does vaccination do to your child’s body?
   A. Vaccination prevent illnesses in children
   B. Vaccines treat illnesses in children like drugs
   C. Vaccines provide nutrients to children like food
   D. I do not know

8. Please mention any disease vaccination can prevent:
   (Use this list to assess mothers’ response: Tuberculosis, Diphtheria, Whooping cough, Tetanus, Poliomyelitis, Hepatitis B virus infection, Measles, Pneumococcal pneumonia)
   A. Mother mentions four (4) or more diseases
   B. Mother mentions three (3) or fewer diseases
   C. I do not know any diseases vaccination can prevent

9. When do you start to vaccinate a child?
   A. Just after birth
   B. 1 week after birth
   C. 2 weeks after birth
   D. 1 month after birth
   E. Anytime
   F. I do not know

10. When does a child complete his routine vaccination?
    A. 6 months
    B. 9 months
    C. 12 months (1 year)
D. 15 months 
E. 2 years 
F. 5 years 
G. I do not know 

11. **Do you know the right age or schedule for routine vaccination of infants?**  
*Use vaccination schedule on the paper titled, ‘NPHCDA routine immunization schedule’ to assess mothers’ response*  
A. Mother mentions correct schedule for three (3) or more vaccines  
B. Mother mentions correct schedule for one or two vaccines  
C. I do not know 

12. **How many visits are needed to complete the immunization for a child**  
A. One (1) visit  
B. 2 or 3 visits  
C. 5 or 6 visits  
D. I do not know 

13. **Using the Google Map app on your phone, how far is the nearest vaccination centre to this house?**  
A. Less than 30 mins walk  
B. About or more 30 mins’ walk 

### Section C: Immunization status

If you answered YES to Question 1 above, which of these vaccines has he/she received?

**Step 1:** FIRST, ask the mothers to know how many vaccinations she can recall, and tick accordingly  
**Step 2:** Then, cross check with the Vaccination/Immunization Card, if available, and tick accordingly

| S/n | Vaccine            | Age         | 1). Mothers recall | 2). Immunization Card |
|-----|--------------------|-------------|---------------------|-----------------------|
|     |                    |             | YES | NO | YES | NO |
| 1   | BCG                | At birth    |     |    |     |    |
| 2   | OPV-1              | 6 weeks     |     |    |     |    |
| 3   | OPV-2              | 10 weeks    |     |    |     |    |
| 4   | OPV-3 or Polio vaccine | 14 weeks |     |    |     |    |
| 5   | Pentavalent – 1    | 6 weeks     |     |    |     |    |
| 6   | Pentavalent – 2    | 10 weeks    |     |    |     |    |
| 7   | Pentavalent – 3    | 14 weeks    |     |    |     |    |
| 8   | Vitamin A          | 6 months    |     |    |     |    |
| 9   | Measles vaccine    | 9 months    |     |    |     |    |
| 10  | Yellow fever       | 9 months    |     |    |     |    |

**The END**

Thank the mother profusely .... Daalu nnukwu / Thank you very much!!
