**Abstract**

**Objective** Topical application of ambonese banana (*Musa paradisiaca* var. *sapientum* (L.) kuntze) stem sap gel (GEGPA) on the socket wound area showed an increase in the expression of platelet-derived growth factor-BB, while decrease in the expression of matrix metalloproteinase-2 and 9. The aim of this study is to achieve standard formulation of GEGPA through stability, viscosity, distribution area, and drugs release for oral gel wound healing.

**Materials and Methods** This is an *in vitro* and *in vivo* study with the randomized posttest only control group design. The gel was formulated according to the composition of each group by adding hydroxypropyl methylcellulose (HPMC), Lexgard, propylene glycol, and cold water to obtain 100 g of gel. Observations were made through the following tests: stability, viscosity, distribution area, drug release, and histopathological analysis of tooth extraction wound healing.

**Statistical analysis** Data were analyzed using a one-way analysis of variance (α = 0.05) with GraphPad Prism-8 statistical software.

**Results** The study showed that the GEGPA formulation was stable against changes in consistency, color, smell, homogeneity, and pH value. There is a significant difference between groups with respect to viscosity (p = 0.0001), adhesion (p = 0.004), dispersion (p = 0.000), and fibroblast cell numbers on days 3 and 5 (p = 0.007 and p = 0.001). There is no interaction between the active ingredients and the gel base of all formulations. Formulation 3 had better properties in terms of viscosity, broad distribution, and drug release compared with other groups. Application of GEGPA to tooth extraction wounds showed a significant proliferation of fibroblast cells on days 3 and 5.

**Conclusions** The formulation of *M. paradisiaca* var. *sapientum* (L.) kuntze extract with HPMC and propylene glycol obtained a gel preparation, GEGPA, that was organoleptically stable and met the topical gel standard for wounds in the oral cavity.

Introduction

Wound healing is a defense mechanism that works by repairing damaged cells or tissues.\(^1\,^2\) The healing consists of a complex series of biological processes that involve cells and surrounding tissues supported by inflammatory and anti-inflammatory cytokines. The oral cavity is a remarkable environment in which wound healing process occurs in the presence of millions of microorganisms in warm oral fluids.\(^3\) Topical or oral medications are used to localize wounds, relieve pain, prevent contamination, and promote healing.\(^4\,^5\)

The drug can be administered topically by applying it on the skin or mucosal surface.\(^6\) Drugs that are commonly used for topical administration to the skin are usually in the form of creams, lotions, or ointments,\(^7\) while drugs that are usually used for treating oral mucosa wounds are generally in the form of gels.\(^8\,^9\) The success of topical treatment depends on patient age, selection of appropriate topical agents, location and area of the affected or diseased body, stage of disease, the concentration of active ingredients in the vehicle, methods of application, determination of drug-use duration, and penetration of the topical drug into the skin/mucosa.\(^10\,^11\) Topical drug administration may be considered in patients with gastrointestinal disturbances, contraindications, or difficulty of swallowing.\(^12\)

Ambonese banana (\textit{Musa paradisiaca} var. sapientum (L.) kunze) is one of the tropical plants that are often used as herbal medicines. The banana tree can be used as an alternative in the treatment of wounds, fevers, insect bites, digestive disorders, and epilepsy.\(^13\) The stem sap extract of ambonese banana contains lectins, palmitic acid, leucocyanidin, quercetin, 3-O-galactoside, 3-O-glucoside, and 3-O-rhamnosyl glucoside,\(^14\) and has analgesic, anti-inflammatory, antibacterial,\(^15\) and antioxidant properties.\(^16\) These also increase fibroblasts proliferation through the induction of growth factors such as \textit{platelet-derived growth factor BB} (PDGF-BB) and \textit{transforming growth factor-f1} (TGF-\(\beta1\)).\(^17\) The use of ambonese banana stem sap extract gel (GEGPA) in fibroblast cell culture shows that it is relatively nontoxic up to a concentration of 100%.\(^18\) The increase in collagen in the wound area that was given the GEGPA can be caused by decrease in \textit{matrix metalloproteinase}-2 and 9 expressions, as well as the antioxidant activity of active compounds in it.\(^19\) The gel consistency greatly affects the ease of its application on the oral wound area. The use of gel-forming materials such as hydroxypropyl methylcellulose (HPMC) in the preparation of ambonese banana stem sap extract has not been proven to interfere the wound healing process after extractions.

The gel is a semi-solid form that is clear, translucent, and contains active substances. It is also a colloidal dispersion that has force caused by tissues that are bonded to each other in the dispersed phase.\(^20\) This gel form has several advantages such as its nonstickiness, the little concentration of gelling agents that is required to form good gel mass, and the gel viscosity that will not change significantly at storage temperature.\(^21\) Every drug should have a good stability; therefore, the pharmaceutical form must be considered carefully. This is very important considering the drug forms that are generally made in large quantities and require long-term storage. If a drug is stored for a long period of time, it can decompose and result in the reduced effects received by the patient.\(^22\) A good formulation is needed for optimum drug stability and the factors that influence the stability of a new drug. This study aims to obtain a suitable gel formulation, so that the stability, viscosity, distribution, and release of active compounds in ambonese banana stem sap extract are maintained as a potential drug.

Materials and Methods

\textbf{Ambonese Banana Stem Sap Preparation}

The plant was determined in the Lembaga Ilmu Pengetahuan Indonesia, Purwodadi, East Java. Ambonese banana stems were cleaned of dirt with running water. The sap from the ambonese banana stem was taken by extracting it. The stems were cut into thin strips with a thickness of 0.5 to 1 cm and dried using an oven (MMM, GmbH) at 40°C for 3 hours. The dried stems were made into powder and then weighed as much as 1 kg. The maceration process was performed with 2 liters of 96% ethanol. The maceration process with ethanol solvent was performed twice, up to 7 days. The results of the maceration were filtered using filter paper (Whatman number 41), and then separated between the extract and solvent using an evaporator (Heidolph-VAP, Germany) at 40°C with 200 rpm speed for 2 hours, to obtain a thick extract. The extract was stored in a closed, dark container and protected from light.

\textbf{Ambonese Banana Stem Sap Gel (GEGPA) Formulation}

The gel was formulated according to the composition in \textit{Table 1}, and the required ingredients were weighed. HPMC was dispersed into 30 mL of water at 80 to 90°C until it expanded. It was then stirred until a clay (gel) was formed. The stirring process must be in a cold state such as a basin that had been given ice cubes. Lexgard was mixed in propylene glycol according to the groups (F1, F2, F3); then the extract was added until it was properly mixed. The mixture was added to the HPMC mixture and stirred until it was homogenous. Cold water was added to get 100 g of gel; then it was packed in a tightly sealed tube. In the control group (K), no extract was added.

\textbf{Table 1} The formulation of the ambonese banana hump extract gel (GEGPA)

| Material Material concentration (%) b/b | F1 | F2 | F3 |
|-----------------------------------------|----|----|----|
| Active material                          | 1  | 1  | 1  |
| HPMC                                    | 4  | 4  | 4  |
| Propylene glycol                         | 10 | 15 | 20 |
| Lexgard                                  | 0.01| 0.01| 0.01|
| Aqua ad                                  | 100| 100| 100|

Abbreviations: F1, formulation 1; F2, formulation 2; F3, formulation 3; HPMC, hydroxypropyl methylcellulose.
Gel Stability Test
The stability of GEGPA was tested at room temperature by observing (organoleptic) the color, smell, homogeneity, pH, and viscosity. Samples were stored at 4°C for 24 hours. After that, the samples were taken out and placed at 40°C for 24 hours. This treatment is counted as one cycle. The experiment was repeated for six cycles while taking the physical conditions into account during the experiment by comparing the previous forms.

Gel pH Test
pH testing on GEGPA was done by inserting the pH meter electrode (Mettler Toledo S220, Merck) into the gel. The gel's pH value will be displayed on the pH meter's screen. The recording of the pH value is awaited until the number on the screen does not change (stable). A suitable gel preparation has a pH value that is near to the oral pH, which is between 6.2 and 7.6.

Gel Viscosity Test
The viscosity test is used to determine the viscosity of the gel preparation by using a viscometer (Haake 6R viscometer, Thermo Scientific, Germany). The gel preparation sample was put into a glass beaker and placed under a spindle hanger. The spindle is installed on the spindle hanger; then it was lowered to the limit immersed in the extract gel preparation. Next, the rotor was turned on while pressing the button. The spindle was allowed to rotate and the red needle was observed on the scale; then the number indicated by the needle was read.

Gel Homogeneity Test
The homogeneity test was performed by weighing 0.1 g of each sample. Furthermore, the sample is smeared on an object glass, and the homogeneity of the preparation and the presence of air bubbles were observed under a microscope at a 100× magnification.

Gel Adhesion Test
The adhesion test was performed by means of 0.25 g of sample placed on top of two predetermined glass objects, then pressed with a load of 1 kg for 5 minutes. The glass object was put on the test equipment and then a load of 80 g was added. The time it takes for the glass object to come off is the stickiness ability of the gel that is going to be recorded and tabulated.

Gel Dispersion Test
The dispersion test was performed by weighing the gel preparation as much as 0.5 g; after that the gel was placed right under a round glass underneath, accompanied by a diameter scale. Next, it was covered with another glass that had been weighed and then allowed to sit for 1 minute. The scatter diameter of each gel was then measured. After 1 minute, a 50 g load was added and allowed to sit for 1 minute. Next, the diameter of the spread was remeasured. This was repeated every 1 minute with the addition of a 50 g load until a sufficient diameter was obtained to observe the effect of the load on the diameter of the spread of the gel preparation.

Power of Diffusion and Permeation Tests
The gel diffusion test was performed with a Millipore synthetic membrane, which was placed between two halves of the diffusion cell. Then, the receptor was filled with phosphate buffer of 6.8 pH and 5% ethanol to 130 mL at 37°C. One gram of gel was applied to the membrane. The absorption was measured every 30 minutes to 8 hours at a 274 nm wavelength with an ultraviolet-visible spectrophotometer (Shimadzu 1800).

Histopathology of Fibroblast Cells on Tooth Socket Wound Healing
This research has passed the health ethics test with number: 586/HRECCEFOM/D/IX/2020. The experimental animals were 24 male rats, Wistar type, 2 to 3 months old, and divided into 4 groups. Rats were anesthetized according to their body weight (30 mg/kg thionembutal). After the rats were anesthetized, the wound was made by extracting the mandibular left incisor. In the control group (K), the socket was only given the drug carrier gel. The treatment group was given GEGPA with different formulations, namely F1, F2, and F3. The gel was injected into the dental socket of Wistar rats using modified needle (as much as 1 to 2 mL of tuberculin syringe). After tooth extraction, the wound was closed by suturing using 5–0 Vicryl (Ethicon, Johnson & Johnson do Brasil, São Jose dos Campos, SP, Brazil). Decapitation was performed on days 3 and 5; then the tissue was washed to remove the residual blood with 0.9% sodium chloride physiological solution and fixed using 10% neutral buffer formalin. The mandible bone was decalcified using 10% ethylenediaminetetraacetic acid (Sigma) and then paraffin blocks were made. The preparations were made with a 4 µ thickness for histological examination of fibroblast cells in the apical one-third of the extraction socket. The preparations were observed using a light microscope (Nikon H600L) with 400× magnification in five fields of view, equipped with a calibrated micrometer. The preparations were processed using the Nikon Image System software and a 300 megapixels DS Fi2 digital camera.

Statistical Analysis
Data were tabulated and analyzed using a one-way analysis of variance (ANOVA) test with GraphPad Prism-8 statistical software at 95% significance. Differences in the mean value of viscosity, adhesion, dispersion, and the number of fibroblasts were analyzed statistically by one-way ANOVA. The gel diffusion and permeation data were analyzed by regression.

Results
Organoleptic Observations of GEGPA
The four formulations showed that in the control group a clear, homogeneous gel was formed, with a typical smell of...
gel base, 6.8 pH, and thick viscosity. In the three groups of GEGPA formulations, there are no organoleptic differences between the gel samples. The gel is clear brown, homogeneous, has a typical banana smell, and thick viscosity. The experiment was repeated for six cycles and compared with the previous forms. Physically, no significant change is found between groups with respect to color, smell, homogeneity, pH, and viscosity, but there is a decrease in the pH of 0.1 in the F1 and F2 groups. The formulation of F3 is more stable compared with the treatment groups (Table 2).

### The Difference in Gel Viscosity of GEGPA

Viscosity testing aims to determine the value of the viscosity of a substance. The higher viscosity of the gel will make the gel thicker resulting in more difficult drug to spread. There is a decrease in the viscosity of each formulation with increase in the volume of propylene glycol that had been used. Sequentially, the highest viscosity values are: the control group2009; 003E;2009; F12009; 003E;2009; F22009; 003E;2009; F3, with a value of 3,592; 3,187; 2,438; and 2,035 cps (Fig. 1). There is a significant difference in the viscosity values of each group ($p$ = 0.000).

### Gel Adhesion Ability of GEGPA

The gel adhesion test is intended to determine the ability of the gel to adhere to the oral mucosa. The gel adhesion test was evaluated by observing the length of time the glass objects remained attached. There is a significant decrease in the length of attachment time in each group ($p$ = 0.004). Obviously, the GEGPA formulation can affect the time length of adhesion (Fig. 2).

### Gel Dispersion of GEGPA

Gel examination is intended to determine the ability of the gel to spread in the oral mucosa. The GEGPA distribution in the F3 group was wider than in the other groups (Fig. 3). Sequentially, the widest dispersion ability is: F3 > F2 > F1 > control, with a value of 21.76, 17.91, 14.05, and 12.37 mm$^2$ (Fig. 4). There is a significant difference in dispersion ability between groups ($p$ = 0.000).

### Diffusion and Penetration of GEGPA across Membranes

As per the results (Fig. 5), the spectrophotometer data for the maximum absorbance of the gel are at 274 nm wavelength in a 6.8 phosphate buffer solution. Referring to Lambert Beer’s law of the standard solution with a concentration of 10 to 180 µg, it is found that the linearity ($r^2$) is 0.999, and regression value ($Y$) is 0.0171X + 0.003. From this graph, the results indicate that there is no interaction between the active ingredients and the gel base of all formulations (F1, F2, and F3).

### Table 2 Organoleptic observations of gel formulations

| Physical properties test | Formula |
|--------------------------|---------|
|                         | Control (Base) | F1                  | F2                  | F3                  |
| Color                   | Clear     | Clear brown         | Clear brown         | Clear brown         |
| smell                   | Typical base| Specialty banana   | Specialty banana   | Specialty banana   |
| pH                      | 6.8       | 6.7                 | 6.7                 | 6.8                 |
| Viscosity               | Thick     | Thick               | Thick               | Thick               |
| Homogeneity             | Homogeneous| Homogeneous         | Homogeneous         | Homogeneous         |

Abbreviations: F1, formulation 1; F2, formulation 2; F3, formulation 3; HPMC, hydroxypropyl methylcellulose.

Note: Description: Control, base (HPMC 4%), F1, Eq. 1; F2; Eq. 2; F3, Eq. 3.
Fibroblast Proliferation in the Healing Process of Tooth Sockets

There is a significant increase in the number of fibroblast cells in the tooth socket on healing days 3 and 5 in the groups that were given GEGPA, which are F1, F2, and F3, compared with the control group (\( p = 0.007 \) and \( p = 0.001 \); Table 3). The apical one-third of the socket in groups F1, F2, and F3 appears to be filled with fibroblast cells more rapidly (Fig. 6). There is no significant difference in the number of fibroblasts in the F1, F2, and F3 groups on days 3 and 5 (\( p = 0.207 \) and \( p = 0.112 \)). The number of fibroblast cells in the control group appears to be lesser than the group given GEGPA.

**Table 3** The average number of fibroblast cell proliferation on days 3 and 5

| Groups | Count of fibroblast cells (\( \bar{x} \pm SD \)) |
|--------|----------------------------------|
|        | Day 3 | Day 5 |
| Control| 8.3 ± 0.52 | 12.1 ± 0.86 |
| F1     | 16.7 ± 0.75 | 22.3 ± 1.13 |
| F2     | 18.1 ± 0.66 | 24.3 ± 1.02 |
| F3     | 8.3 ± 0.52 | 25.7 ± 1.15 |

Abbreviations: SD, standard deviation; \( \bar{x} \), mean. \( *p \)-Value, significance level 0.05.

Discussion

A lot of research has been done to get a material that can accelerate the wound healing process in the oral cavity, as well as reduce postoperative complications. In controlling complex microorganisms in the oral cavity, topical wound protection agents are surely needed, besides oral drugs to reduce pain, inflammation, and infection. Oral drug use will give absorption, metabolism, distribution, and excretion (ADME) effect, as well as first-pass metabolism. Disruption of ADME results in reduced drug availability in the systemic circulation, and low-found drug concentrations in tissue. Recent researches in dentistry are mainly focused on the development of local agent’s use or drugs that are applied directly to the wound area. It is hoped that the local/topical administration will be more effective because it can be absorbed directly and interact with surrounding cells and tissues. Oral gel formulations may reduce side-effects in patients with gastrointestinal disorders if taken orally, or in patients with medical conditions such as dysphagia. In addition, there are many oral gel products that are available commercially, most of which are quick-release formulations that release the active ingredient by diffusion.

In this study, HPMC was used for making the GEGPA preparations, which act as a gelling agent. HPMC will form a colloidal system when dissolved in water. Lipophilic colloids are generally organic molecules that can be dissolved with molecules from the dispersing phase. HPMC is non-toxic and has good water binding ability. The use of 4% HPMC in GEGPA preparations produces the appropriate...
A good gel has a viscosity of 5 to 80%. Propylene glycol is often used in gel preparations because it has low toxicity. The use of propylene glycol can also increase drug penetration. Propylene glycol is used because it has hydrophilic and hydrophobic groups, so it can dissolve hydrophobic compounds. In addition, propylene glycol is a cosolvent with low toxicity. GEGPA formulations that consist of ambonese banana stem extracts, HPMC, and propylene glycol, produced a brownish clear gel with thick viscosity and a typical banana scent. The GEGPA formulation has a slightly decreased pH, namely by 0.1, compared with the pH of the control group, which is 6.8. The pH value of GEGPA still meets the requirements for a normal oral pH environment, which is between 6.7 and 7.3, and saliva with a pH between 6.2 and 6.7. The use of 20% propylene glycol can balance the pH of GEGPA, so that it becomes the same as the pH of the control group. It is possible because in GEGPA preparations, the compound in ambonese banana stem sap can lower the pH of propylene from 9.0–10.5 to 6.7–6.8.

The viscosity of the GEGPA formulation is also less compared with the control group. A good gel has a viscosity between 2,000 and 4,000 cps. The GEGPA formulation has a viscosity between 2,035 and 3,187 cps, so the results of this study indicate that the GEGPA formulation meets the requirements of a fairly good oral gel. Due to the encouragement of blood flow that comes out of the wound, the appropriate gel viscosity can inhibit gel detachment from the mucosa. The thicker the gel or the higher the viscosity of the gel, the more difficult it is for the active ingredient to be separated from the carrier material and the longer is the penetration time into the tissue, so the absorption of the active ingredient can decrease. The increase in viscosity can also affect the adhesion of the gel to the mucosa. The gel is considered appropriate when the drug can diffuse quickly into the wound.

The dispersion of the gel is increased at a low viscosity. Viscosity affects the dispersed area. Thus, the greater the viscosity value of the gel preparation, the greater is the resistance of the gel preparation to spread, resulting in a decreasing dispersion value. Conversely, if the viscosity value of the gel preparation is getting smaller, the resistance of the gel preparation to spread will also be getting smaller, and so it will have a wide dispersion. The spreadability of the GEGPA formulation in the F3 group is wider than in the other groups. So, when applied to the application site, this ensures that the formulation maintains a good wet contact time.

Therefore, the active ingredients used in these formulations can be combined with the excipients used in all of these gel formulations. From the comparison of the three formulations above, it can be seen that the third formulation experienced the best release of active ingredients compared with other formulations. In an in vitro study, it was found that formula 3 was released by permeate diffusion of 94.01% for 8 hours, so that formula 3 can describe the increase of the active ingredient penetration and absorption.

The patient’s well-being may be harmed by a delayed tooth extraction socket healing process, which increases the risk of infection. The proliferation phase of fibroblast proliferation is a crucial stage in the healing process. Bone development in the socket is facilitated by fibroblasts made up of extracellular matrix and collagen fibers. Fibroblasts are particularly critical cells in the early stages of wound healing, and they begin to form on the third day following injury during the proliferative stage. Fibroblasts begin to move to the wound site and proliferate between days 3 and 5, resulting in a dominance of their numbers on the wound site. The use of GEGPA inserted into the tooth sockets of mice shows an increase in the number of fibroblasts on days 3 and 5. Phytochemical compounds in GEGPA such as lectins, palmitic acid, leucocyanidin, quercetin, 3-O-galactoside, 3-O-glucoside, and 3-O-rhamnosyl glucoside can be released from the gel, and play an important role in activating PDGF-BB and TGF-β1, so that they can increase...
fibroblasts’ proliferation in the tooth socket area. The distribution of these compounds in the form of a gel can certainly accelerate wound healing.

**Conclusions**

The formulation of *M. paradisiaca* var. *sapientum* (L.) kuntze extract with HPMC and propylene glycol obtained a gel preparation, GEGPA, that was organoleptically stable and met the topical gel standard for wounds in the oral cavity.
