We showed that motor intracortical inhibition (ICI) is significantly reduced in migraineurs with aura and six controls underwent a paired-pulse TMS paradigm to evaluate ICI and ICF of the motor cortex before and after conditioning high frequency rTMS followed by 1 Hz rTMS train. Patients were examined intercritically at least 48 h before or after an attack. The hot-spot for the right abductor pollicis brevis (APB) was checked by mean of a figure-of-eight coil and motor threshold (MT) on this record point. ICI and ICF were assessed by means of a conditioning stimulus (CS) at 80% MT followed by a test stimulus (TS) at 120% MT, with two different inter-stimulus intervals: inhibitory: 2 ms and facilitatory 10 ms. Priming rTMS (900 stimuli at 10 Hz frequency, in trains of 50 stimuli separated by 45 s intervals) was followed by a single 15-min-long train (900 stimuli) at 1 Hz rTMS. rTMS was delivered at 90% of MT over the hot-spot. Motor evoked potential (MEP) amplitude of TS post-rTMS was expressed as percentage of baseline MEP. Amplitude of MEPs recorded at 2 and 10 ms ISIs before and after rTMS were expressed as percentage of change from the respective mean TS alone.

Results At baseline, ICI was significantly lower in migraineurs with aura and six controls. In healthy controls, MEP amplitude and ICF were significantly reduced by priming 1 Hz treatment with respect to baseline values. In contrast, the priming stimulation significantly increased ICI in migraineurs, leaving quite unchanged MEP amplitude and ICF values with respect to baseline.

Conclusions In migraineurs, rTMS-priming potentiates intracortical inhibition and reverses the paradoxical increase in ICF observed with 1 Hz rTMS [1]. These findings strengthen the hypothesis of reduced inhibition in migraine with aura and might open perspectives for new treatment strategies.

**EFFECTS OF REMOTE CUTANEOUS PAIN ON TRIGEMINAL LASER EVOKED POTENTIALS IN NORMAL SUBJECTS AND MIGRAINE PATIENTS**

M. de Tommaso, M. Sardaro, C. Pecoraro, O. Difruscolo, M. Livrea Neuropathophysiology Unit of Chronic Pain, Department of Neurological and Psychiatric Sciences, University of Bari, Bari, Italy; e-mail: m.detommaso@neurol.uniba.it

Introduction In a previous study a different modulation of trigeminal laser evoked potentials (LEPs) was detected in migraine patients vs controls during topical application of capsaicin on the supraorbital skin. The inhibiting central effect exerted in controls by capsaicin on trigeminal LEPs was less evident in migraine, suggesting a disturbed pattern of pain modulation at the cortical level, which may subtend the onset and persistence of migraine [1].

Objective The aim of the present study was to detect the functional changes of trigeminal LEPs during topical application of capsaicin over a remote site of the body in migraine patients outside the attacks vs. non migraine healthy controls.

Methods Ten patients suffering from migraine without aura (ICHD-II, 2004), free from pain and symptomatic drugs for at least 72 hours and not taking preventive treatment for migraine were selected for the study. Eight age- and sex-matched healthy controls were also examined. LEPs were recorded by 31 scalp electrodes, referred to the nasion, stimulating the dorsum of the right hand and the right supraorbital zone in basal conditions and 30 minutes after application of 3 mL of 5% capsaicin in a cream base (Teofarma), which was applied topically on the entire surface of the dorsum of the left hand, within an area.
Some studies suggested that migraine is associated with

Patients underwent a full-night laboratory nocturnal video-polysomnography following adaptation. Patients slept in a sound-proof room. A wrist actigraphic study was also performed in patients with HH and CH.

SLEEP STUDIES IN PRIMARY HEADACHES

1. de Tommaso M, Losito L, Difruscolo O et al (2005) Changes in cortical processing of pain in chronic migraine. Headache 45:1208–1218

Introduction Primary headaches have an intimate relationship with sleep. Although strictly sleep-related headaches, such as hypoxemia-related headache, cluster headache (CH) and hypnic headache (HH) are less prevalent and more easily recognized, other primary headaches are often impacted to some degree by sleep.

Objective The aim of the study was to describe the results of sleep studies performed in different forms of primary headache and their pathophysiological correlates.

Methods Patients underwent a full-night laboratory nocturnal video-polysomnography following adaptation. Patients slept in a sound-proof room. A wrist actigraphic study was also performed in patients with HH and CH.

Results Hypnic Headache: The most relevant finding regarding sleep structure was the quantitative reduction of rapid eye movement (REM) sleep. Actigraphic recordings showed that the index of motor activity was consistently increased following the start of effective drug treat-

Cluster Headache: No modifications of polysomnographic arousal parameters across the recordings were observed in the acute phase, when compared with the interictal phase, except for the arousal index in REM sleep. At a microstructural level, the arousal index calculated in REM was much lower in the nights in which attacks occurred. Actigraphic recordings revealed, moreover, that the patient’s sleep-wake schedule was irregular during the CH period and progressively modified, becoming more regular after remission. All the observed modifications are consistent with an abnormal function of the posterior or hypothalamus.

Sleep-related migraine: Evaluation of the pattern of arousal from sleep in a group of patients affected by sleep-related migraine showed a lower continuous airway pressure (CPAP) rate in non REM sleep and, in particular, a lower number of A1 phases (low-frequency, high-amplitude EEG bursts) compared with controls. Migraineurs also showed a lower index of high-frequency EEG arousals during REM sleep. Reduction in the CPAP rate indicates a lower level of arousal fluctuation in non REM sleep. The reduced arousal index in REM sleep suggests a dysfunction in neural structures involved in both the control of REM sleep and the pathophysiology of migraine, such as the hypothalamus and the brainstem.

Conclusions We believe that sleep studies, including both macro- and microstructural analysis of sleep and actigraphy, may be useful in clarifying the pathogenic mechanisms of primary headaches.

DESTABILIZING CONDITIONS IN MIGRAINE PATIENTS EVALUATED BY COMPUTERIZED STATIC STABILOMETRY

1. Rossi, 1 P. Sarchielli, 1 F. Coppola, 1 P. Calabresi, 2 M. Faralli, 2 G. Ricci, 2 A. Frenguelli

1Headache Centre, Department of Medical Surgical Specialties and Public Health, 2Otolaryngology Clinic, University of Perugia, Perugia, Italy; e-mail: mentira@libero.it

Objective The aim of this study was to assess the presence of destabilizing inputs that, by acting on vestibulo-sensory pathways, are able to induce postural changes and imbalance conditions in migraine patients during the interictal period, by computerized static stabilometry.

Material and methods Twenty patients were studied (14 F and 6 M; mean age 32.6 years) affected by migraine without aura (MO) according to ICHD-II, 2004 criteria and were compared with 35 controls. The stabilometric parameters considered were: statokinesigram surface (S) in eyes open (EO) and closed (EC) conditions, EC with head retroflexion (ECR), EC condition with occlusal bite, and optokinetic stimulation (OKN). Regarding the OKN condition, we used two different kinds of stimulation: the “look” (active) type, in which the patient must follow with the eyes the visual stimulation running through the monitor, and the “stare” (passive) type, in which the patient must look at a fixed point on the monitor and not the visual stimulation crossing the monitor.

Results We found a significant statistical difference (p<0.045) between patients and controls in only one stabilometric condition, the OKN stimulation. In particular, the OKN “stare” stimulation was more destabilizing for migraine patients than for controls, inducing conditions of imbalance.

Conclusions In MO patients, the alterations appear under optokinetic stimulation and support a control impairment in involuntary oculomotor control of central origin. This is suggested by recent stabilometric findings of our group [1].

Introduction Some studies suggested that migraine is associated with an impaired activity of the autonomic nervous system [1]. It is known that the subject with migraine has a reduction in R-R intervals and a reduction in the increase of the heart rate during “handgrip” in comparison with the control group [2].

Objective The objective of our study was to analyse in subjects with migraine with aura the heart rate variability (HRV), evaluated in time and frequency domains by means of ECG holter during 24 hours.

Patients and methods We recruited subjects with migraine with aura during headache-free periods, without treatment. The control group consisted of age- and sex-matched healthy control subjects. Autonomic nervous system function was evaluated by HRV analysis during 24-hour ECG recording, SDNN (millisecond, total autonomic
HIGH-FREQUENCY OSCILLATION SOMATOSENSORY EVOKED POTENTIALS: EVIDENCE OF A REDUCED THALAMO-CORTICAL ACTIVATION IN MEDICATION-OVERUSE HEADACHE

1G. Coppola, A. Ambrosini, J. Schoenen, F. Pierelli
2Research Foundation for the Study of Ophthalmology “G. Bietti”, Rome, Italy; 3IRCCS-Neuromed, Pozzilli, Isernia, Italy; 4Headache Research Unit, University Departments of Neurology and Neuroanatomy, University of L’Aquila Chir Ciutadell, Belgium; 4University of Rome “La Sapienza”, Polo Pontino, I.C.O.T., Latina, Italy; e-mail: gianluca.coppola@uniroma1.it

Background Recently, studies using FDG-PET techniques have reported hypoacltivation of nuclei belonging to the “pain network” in patients with medication-overuse headache (MOH). In particular, it has been shown that the ventral postero medial thalamic nuclei were hypometabolic in migraineurs suffering from MOH [1]. Since the high-frequency oscillations (HFOs) embedded in the broad-band SSEPs. Right median nerve SSEPs were recorded from the contralateral parietal area in 9 patients affected by medication-overuse headache (MOH). In particular, it has been shown that the ventral postero medial thalamic nuclei were hypometabolic in migraineurs suffering from MOH [1]. Since the high-frequency oscillations (HFOs) embedded in the common somatosensory evoked potentials (SSEPs) recording reflect spike activity in thalamo-cortical cholinergic fibers (early HFOs phase) and cortical inhibitory GABA-ergic interneurons (late HFOs phase), we studied a group of MOH patients with this neurophysiological approach.

Materials and methods Right median nerve SSEPs were recorded from the contralateral parietal area in 9 patients affected by medication-overuse headache (MOH, ICHD-II 8.2) and in 9 healthy volunteers (HV). Digital off-line filtration (band-pass between 450 and 750 Hz) was employed in order to extract the high frequency (600 Hz) oscillations embedded in the broad-band SSEPs.

Results The amplitudes and latencies of conventional broad-band SSEPs showed no between-group differences. After applying the digital filter, we found a significant decrease of maximal amplitude (p=0.030) and area under the rectified curve (p=0.038) of the early SSEP HFO component in patients compared to HV. By contrast, no difference was found for the late SSEP HFO component.

Discussion These results show thalamo-cortical hypoactivity in patients with MOH. This is in line with the previous FDG-PET study showing thalamic hypometabolism. The absence of SSEP HFO late component changes suggests normal intracortical inhibition at the level of the somatosensory cortex in this patient group.

Conclusion Experimental findings from animal pain models support the role of nerve growth factor (NGF) and brain-derived neurotrophic factor (BDNF) as putative candidates intervening in the pathogenesis of chronic pain. Few studies have been carried out to establish their role in maintaining the pain states in humans and their involvement in chronic migraine (CM) and fibromyalgia [1, 2].

Objective The present study was aimed at investigating cerebrospinal fluid (CSF) levels of NGF and glutamate measured by sensitive immunoassay and by HPLC respectively in CM patients and patients affected by primary fibromyalgia syndrome (PFMS), comparing values with those of 20 age-matched control subjects.

Material and methods Twenty consecutive patients suffering from CM according to ICHD-II classification and attending the Headache Centre of the Neurologic Clinic of the University of Perugia were admitted to the study. A further patient group included 20 patients affected by PFMS. Diagnosis of PFMS was made according to the American College of Rheumatology Criteria (1990). All patients were admitted to the Neurologic Clinic to undergo lumbar puncture. Control CSF specimens were obtained from 20 age-matched subjects who underwent lumbar puncture for diagnostic purposes. In all subjects CSF and blood tests excluded CNS or systemic diseases. All control subjects were drug-free for at least two months and none of them were taking any medication at the time of CSF sampling or had a personal or family history of migraine nor suffered from tension-type headache. None of the above controls developed post-lumbar puncture headache.

Results Significantly higher levels of both neurotrophins were found both in patients with CM (p<0.001, p<0.0005) and PFMS (p<0.001 and p<0.001) compared with control subjects, without significant differences between the two patient groups. Both patient groups had significantly higher CSF levels of glutamate than controls (p<0.001 and p<0.003, respectively). A significantly positive correlation emerged between CSF values of BDNF and those of NGF (r=0.61, p<0.001; r=0.53, p<0.01) and glutamate (r=0.44, p<0.02; r=0.51, p<0.01) in both CM and PFMS patients, respectively.

Conclusions These findings suggest the possibility of an NGF-mediated up-regulation of BDNF in central sites involved in long-term sensitization, which plays a key role in persistent, chronic painful conditions, such as CM and fibromyalgia. NGF might indirectly exert its effect through enhancement of glutamatergic transmission via BDNF. The above mechanisms could account for sustained central sensitization in both chronic pain states but cannot be considered specific for just one of these two disorders. They may rather be considered expression of the pathogenic mechanisms underlying chronic pain per se.

ENDOCANNABINOIDS IN PLATELETS OF MEDICATION-OVERUSE HEADACHE PATIENTS AND CHRONIC MIGRAINE PATIENTS: CORRELATION WITH SEROTONIN LEVELS

1C. Rossi, 1LA. Pini, 1P. Calabresi, 1P. Sarchielli
2Neurologic Clinic, Department of Medical and Surgical Specialties and Public Health, University of Perugia, Perugia, Italy; 3Institute of Clinical Pharmacology, University of Modena and Reggio Emilia, Modena, Italy; e-mail: mentira@libero.it

Background Based on experimental evidence of the antinoceptive action of endocannabinoids [1], we hypothesized a dysfunction of this system in medication-overuse headache (MOH) and chronic migraine (CM).

Objective To test this hypothesis, we determined the levels of the endogenous cannabinoid 2-arachidonoylglycerol (2-AG) and arachidonylthanolamide (anandamide, AEA) in platelets of 15 patients affected by MOH according to ICHD-II and 15 patients with CM without medication overuse, as well as in 15 age-matched control subjects. We also investigated the intra-platelet levels of serotonin.

Methods Endogenous cannabinoids were purified from platelet pellets by high-performance liquid chromatography (HPLC), and quantified by isotope dilution gas-chromatography/mass-spectrometry. Serotonin levels were also measured by HPLC.

Results In both patients and controls levels of 2-AG were about 20–fold higher than that of AEA. 2-AG and AEA levels were significantly lower in medication overuse and CM patients than in controls (p<0.02 and p<0.04, respectively), with significant difference between the groups. Serotonin levels were strongly reduced in both patient groups (p<0.001 and p<0.002, respectively) and were significantly correlated with 2-AG and serotonin levels (r=0.48, p<0.01 and r=0.46, p<0.02).

Conclusions The finding of reduced 2-AG and AEA in platelets correlated with reduced serotonin levels may reflect an imbalance in the endocannabinoid system, which occurs in parallel with serotoninergic dysfunction in these two chronic headache conditions. The parallelism in the failure of these two systems is in line with experimental findings of mutual interaction of 2-AG and 5-HT in modulating different signaling pathways, which can also be relevant for pain control. Variations in activity of AEA transporter and AEA hydrolyse in peripheral platelets, as recently shown in female but not male migraineurs [2], remain to be established in MOH and CM.

This study has been partially supported by the Lega Italiana Cefalalgici.

Introduction The wolframin gene (WFS1) is mentioned as being possibly responsible for a heterogeneous combination of psychiatric disorders; in a number of studies it has been suggested that common variants in WFS1 are associated with psychiatric illnesses. For instance, homoygous carriers of the His611Arg polymorphism (R/R genotype) are at increased risk of attempted suicide and generally score higher than non-R/R individuals on both novelty seeking (NS), impulsivity and depression scales. It is well known that psychiatric comorbidity is widely represented in medication-overuse headache (MOH). In the present study we investigated the wolframin His611Arg polymorphism in a sample of MOH patients who submitted to psychiatric, psychometric and clinical assessment.

Materials and methods Fifty-two consecutive, unrelated MOH patients (42 women and 10 men) were recruited. Mean age was 46.37±11.35 years; mean analgesic-drug consumption was 44.8±28.24 doses/month. All the patients were interviewed using the Structured Clinical Interview for DSM-IV Axis I Disorders (SCID-I), to obtain a categorical psychiatric diagnosis, and completed the Beck Depression Inventory (BDI), a self-reported questionnaire for a dimensional assessment of depressive symptoms. The BDI mean score was 13.15±10.01. Thirty-seven lifetime and 36 current psychiatric disorders were diagnosed.

Discussion Even if it has been reported that depression predicts disability and increased drug consumption in headache patients, in our MOH patients we found no direct correlation between depression scores and monthly intake of analgesic drugs. We believe that the increased drug consumption observed in R/R carriers is a consequence of increased impulsivity and NS traits, irrespective of depression. The presence of R/R genotype appears to be an aggravating factor in drug overuse in MOH patients.

Headaches: clinical aspects

ANALYSIS OF PATIENTS ATTENDING A SPECIALIZED HEADACHE CENTRE OF THE CALABRIA REGION OVER A ONE-YEAR PERIOD

1R. Iannacchero, 4V. Rispoli, 2E. De Caro
3Regional Headache Centre, “Pugliese-Ciaccio” Hospital, Catanza, Italy; 2Department of Pharmacobiological Science, University “Magna Gracia” of Catanza; Catanza, Italy; e-mail: rosariiann@tiscal.i.it

Objective Our aim was to analyse the diagnosis, prescribed medications and examinations conducted on patients attending a specialized Headache Centre of the Calabria Region over a one-year period.

Methods An audit of clinical records of patients attending the Headache Centre of the “Pugliese-Ciaccio” Hospital in Catanza, from January 2005 to January 2006, was conducted. Data regarding diagnosis, current medications, prescribed medications, and examinations conducted were collected.

Results Four hundred and fifteen patients attended the clinic during the audit period. Two hundred (48%) of them were diagnosed with chronic daily headache (CDH), 160 (39%) with migraine, 32 (8%) with cluster headache, and 19 (5%) with neuralgia headache TACs. All other diagnoses involved only one patient (<1%) in each case. The most common medications used by patients with CDH at the time of initial consulta-
tion were: analgesics (64%), prophylactic drugs (17%), triptans (14%), and diazepam (3%). Following the consultation, prophylaxis was prescribed for 51% of patients while triptans for only 1%. At the time of initial consultation, patients with migraine were taking: analgesics (59%), triptans (26%), prophylactic drugs (19%), and ergotamine (2%). Following the consultation, prophylactic drugs was recommended for 75% of patients, triptans for 49%, manipulation for 13%, and analgesics for only 10%. Examinations were arranged for 19 patients (9%) and were negative in all cases.

Conclusions Most patients attending our headache centre were suffering from CDH or migraine. Cluster headache was rarely diagnosed. Despite this being a secondary care clinic, most patients were taking analgesics and relatively few specific acute therapies or prophylactic drugs. In contrast, tripton consumption markedly increased following consultation. In all clinical cases, further examinations were negative and were primarily conducted to reassure the patients.

A VALIDATION STUDY OF AN ITALIAN VERSION OF THE “ID MIGRAINE”

1Department of Clinical Neurosciences, University of Palermo, Palermo, Italy; 2Neurology Unit, Villa Sofia Hospital, Palermo, Italy; 3Neurology Unit, Civic Hospital, Palermo, Italy; 4Department of Neurosciences, Caltanissetta, Italy; 5Neurology Unit, S. Elia Hospital, Caltanissetta, Italy; 6Headache Centre, ASL 6, Bagheria, Palermo, Italy; 7Headache Centre, Hospital of Partinico, Partinico, Palermo, Italy; 8Department of Neurosciences, University of Catania, Catania, Italy; e-mail: fbrighina@unipa.it

Introduction Migraine is a highly prevalent and disabling disease that is substantially underdiagnosed in primary care. Recently, the ID Migraine, a self-administered questionnaire, consisting of only three items, was shown to be a valid and reliable screening instrument for migraine in primary care in the U.S.A. The aim of the present study was to validate an Italian version of the “ID Migraine” questionnaire.

Methods A total of 222 consecutive headache patients referring to eight headache centres in Sicily (Italy) completed an Italian version of the ID Migraine. The responses to the questionnaire were compared with the diagnosis of headache made by a headache specialist who did not know the results of the questionnaire. Sensitivity, specificity, positive and negative predictive value and accuracy level for migraine were calculated.

Results The statistical analysis on 222 patients examined showed a very good performance of the ID Migraine with high sensitivity: 0.95 (95% CI, 0.91–0.98), specificity: 0.72 (95% CI, 0.62–0.82) and positive predictive value: 0.88 (95% CI, 0.82–0.93). ID migraine also showed a very good accuracy level: 0.87 (95% CI, 0.83–0.92).

Conclusions This study demonstrated “ID Migraine” to be a valid tool for migraine screening also in Italian patients referring to headache centres. If confirmed in a primary care setting, these results would establish the “ID Migraine” as a valid screening instrument for migraine in the Italian population.

PATIENT COMPLIANCE TO THE DIAGNOSTIC APPROACH IN HEADACHE
L. Savi, P. De Martino, E. Zampella, L. Pinesi
Headache Centre, Neurology II, Department of Neurosciences, University of Turin, San Giovanni Battista Hospital, Turin, Italy; e-mail: lsavi@molinette.piemonte.it

Introduction One of the most important tools in the approach to a headache patient is the headache diary, whose compilation is a fundamental step in the formulation of the definitive diagnosis and in the organization of a therapy, which must be appropriate to the individual patient. The Headache Centre of the University of Turin began many years ago to use such a diary which, though modified and improved in the course of time, is still fundamentally the same.

Objective The purpose of this study was to evaluate the patient compliance to the compilation of the headache diary.

Materials and methods A total of 575 patients (133 males and 442 females, age range 18–85 years) attending for the first time the Headache Centre of the University of Turin in the period January 1 - December 31, 2004, were enrolled in the study. They all suffered from various kinds of primary headache diagnosed according to the International Headache Society criteria (ICHD-II).

The usual diagnostic approach to the patients at the Headache Centre of the University of Turin starts with a first visit, in the course of which as much information as possible is collected from the patient’s interview, and a symptomatic therapy is suggested. This is followed after three months by a second visit, when a more definitive diagnosis is formulated and, if it is deemed necessary, prophylactic therapy is suggested to the patient.

The patients are given the headache diary at the first visit. They are instructed how to complete it and are asked to be as careful as possible in its compilation. They have to record many different characteristics of their headache (pain, duration, intensity, localization, aggravation by routine physical activity, presence of other symptoms, and drugs used).

It was evaluated how the diary had been filled in by all the patients who came to the second visit, considering their age, level of instruction, type of work, and comprehension of the language.

Results After the first visit 393 patients came back, while 182 did not. Among those who came back, 324 (82.45%) filled the diary completely, while the remaining 69 (17.55%) filled it in only partially or did not fill it in at all.

Discussion and conclusions On the basis of the data it is possible to affirm that the majority of patients showed a very satisfactory compliance to the diary compilation.

PATIENT COMPLIANCE TO COMPIlATION OF THE HEADACHE DIARY
L. Savi, P. De Martino, E. Zampella, L. Pinesi
Headache Centre, Neurology II, Department of Neurosciences, University of Turin, San Giovanni Battista Hospital, Turin, Italy; e-mail: lsavi@molinette.piemonte.it

Introduction One of the most important tools in the approach to a headache patient is the headache diary, whose compilation is a fundamental step in the formulation of the definitive diagnosis and in the organization of a therapy, which must be appropriate to the individual patient. The Headache Centre of the University of Turin began many years ago to use such a diary which, though modified and improved in the course of time, is still fundamentally the same.

Objective The purpose of this study was to evaluate the patient compliance to the compilation of the headache diary.

Materials and methods A total of 575 patients (133 males and 442 females, age range 18–85 years), attending for the first time the Headache Centre of the University of Turin in the period January 1 - December 31, 2004, were enrolled in the study. They all suffered from various kinds of primary headache diagnosed according to the International Headache Society criteria (ICHD-II).

The usual diagnostic approach to the patients at the Headache Centre of the University of Turin starts with a first visit, in the course of which as much information as possible is collected from the patient’s interview, and a symptomatic therapy is suggested. This is followed after three months by a second visit, when a more definitive diagnosis is formulated and, if it is deemed necessary, prophylactic therapy is suggested to the patient.

The patients are given the headache diary at the first visit. They are instructed how to complete it and are asked to be as careful as possible in its compilation. They have to record many different characteristics of their headache (pain, duration, intensity, localization, aggravation by routine physical activity, presence of other symptoms, and drugs used).

It was evaluated how the diary had been filled in by all the patients who came to the second visit, considering their age, level of instruction, type of work, and comprehension of the language.

Results After the first visit 393 patients came back, while 182 did not. Among those who came back, 324 (82.45%) filled the diary completely, while the remaining 69 (17.55%) filled it in only partially or did not fill it in at all.

Discussion and conclusions On the basis of the data it is possible to affirm that the majority of patients showed a very satisfactory compliance to the diary compilation.
first visit; the diary compilation was too complicated (it was a very difficul
task for the patients with chronic headache); the diary was a nui-
sance because the headache attacks were so few; the fee paid for the visit was too high and the visit itself did not offer a solution to their problem; and the patient did not like the doctor’s approach at the first visit.

Discussion and conclusions On the basis of these data it is possible to note that the majority of the patients accept and understand this diagnostic approach, so the criticism towards it does not seem to be realistic. Considering the most frequent motivations reported by the patients who did not come back, it appears likely that providing more information could improve the situation.

PREVALENCE OF ARTERIAL HYPERTENSION IN THE RELATIVES OF MIGRAINE PATIENTS

Introduction Migraine and some cardiovascular disorders should have common pathogenic mechanisms, and genetic factors should play an important role in the possible development of migraine in a subject with a positive gender for cardiovascular disorders [1]. Moreover, in the clinical history of patients affected by migraine the presence of arterial hypertension in their relatives is frequently observed.

Objective The aim of our study was to assess how common this phenomenon is in a population of children and adults.

Materials and methods The study sample included 190 patients affected by episodic migraine without aura (according to ICHD-II criteria, 2004 [2]), without other forms of headache and without other comorbidity. Seventy-four subjects (38.94%), 50 F, 24 M, age range 10–72 years, mean age 39.05 years – Group A) did not refer gender positivity for arterial hypertension, while 116 (61.06%, 86 F, 30 M, age range 10–72 years, mean age 33.97 years – Group B) referred the presence of arterial hypertension in almost one relative of first (parents), second (sister, brother, grandparents) or third degree (uncles or aunts).

Before the visit, a dedicated, specific and simple questionnaire was given to the patient for compilation.

Results In Group B, 83 subjects referred the presence of arterial hypertension in one or both first degree relatives, 76 in second (with or without first) degree relatives, 20 in third (with or without second and first) degree relatives. The mean number of attacks per month was 4.51 in Group A and 5.49 in Group B.

Conclusions This study has two limitations, the small patient cohort and the absence of a control group (without migraine). Nonetheless, we can suppose that migraineurs have a remarkable prevalence of relatives with arterial hypertension, according to previous studies, and that the number of attacks seems to be higher in the group with gender positivity for arterial hypertension.

FOOD INTOLERANCE IN MIGRAINE

Objective Several factors can trigger migraine; among them, dietary factors play a very important role in the onset of migraine attacks. The aim of our study was to evaluate the incidence of food intolerances in a group of migraineurs, by using the Cytotoxic test.

Materials and methods Thirty consecutive patients suffering from migraine presenting to the Headache Centre of S. Luca Hospital, Vallo della Lucania (SA) were examined. Twenty-three were women, mean age 28.2 years, range 13–47 years; 7 were men, mean age was 39.33 years, range 28–62 years. The Cytotoxic test is capable of identifying the presence of specific food intolerances by observing the appearance, the size, the shape or the integrity of leukocytes exposed to extracted food antigens or other materials derived from specific foods.

Results An intolerance was found to: tyramine in 12 women (52.17%); and 3 men (42.85%); milk, 3 women (13.05%); yeast, 4 women (17.39%) and 1 man (14.28%); solanaceae, 4 women (17.39%) and 1 man (14.28%); coffee, 5 women (21.74%); cocoa, 5 women (21.74%); tea, 2 women (8.69%); eggs, 1 woman (4.35%) and 1 man (14.28%); pork, 1 woman (4.35%); and sugar, 1 woman (4.35%).

Conclusions Our study showed a high incidence of food intolerance in migraineurs (in women more than in men). The dietary factors which gave more significant results were tyramine, yeast, solanaceae, coffee and cocoa. These results are in agreement with those of other studies found in the literature, proposing tyramine, coffee and cocoa as very important migraine-precipitating factors. Conversely, there is little evidence of a comorbidity between migraine and intolerance to solanaceae. For this reason, further studies are warranted to confirm this hypothesis.

ALTERATIONS IN GLUCOSE-INSULIN METABOLISM IN MIGRAINEURS: PROSPECTIVE STUDY ON THE CLINICAL IMPACT OF DIET ON MIGRAINE SEVERITY AND METABOLIC DATA IN A MIGRAINEUR POPULATION – PRELIMINARY RESULTS

Introduction Migraine is characterized by a complex biochemical dysfunction attributed to a disorder of the trigeminal and hypothalamic pathways. Impairment of glucose and insulin metabolism has been reported in migraine [1], and insulin alterations seem to be specific to migraineurs.

Objective The main aim was to verify if a proper diet, eventually associated with a insulin-sensitizing drug where indicated, could modify the headache severity together with the glucose-insulin metabolic alteration in migraineurs who presented alterations in glucose-insulin metabolism.

Patients and methods The study population included all migraineurs consecutively seen at the headache centre of our hospital during a one-year period; all the recruited people underwent a general blood test and a standard oral glucose tolerance test (OGTT) after a 12-hour fasting period, measuring levels of glucose and insulin. A daily fragmented low-percentage carbohydrate diet was suggested to those patients who showed an alteration in glucose and or insulin metabolism. Each patient was followed-up during a 3–6 month period, and another standard OGTT was performed, following a 3–6 month period of diet after a 12-hour fasting period, measuring levels of glucose and insulin. Evaluation of headache severity was expressed in severity index, calculated on the basis of the number of days with headache and each day headache severity in 1–3 severity scale (1 mild, 2 moderate, 3 severe).

Results In a 12-month period, we recruited 173 migraineurs (138 women, 35 men), 132 patients had a metabolic glucose-insulin alteration (102 women, 30 men), and 41 patients had normal metabolic profile. Until now, 64 patients have been followed-up for at least 3–6 months. Headache severity index of the studied population was 31
We have recently shown that in patients with migraine, females represented 82% of the study group, and these data seem to be specific to this headache type. These findings are in keeping with recent reports on the effects of insulin on brain functions and lend support to the possible physiological accommodation. Fasting MI was similar in patients with and without migraine, focusing on the characteristics of headache and vertigo and how they interchanged between each other.

**Results**

Both in dyspeptic patients with migraine and without migraine, the mean increase of post-prandial gastric volume was indicative of a physiological accommodation. Fasting MI was similar in patients (migraine 27.5±7.1 mL x min; dyspepsia 26.9±4.6 mL x min) and HV (24.8±4.3 mL x min). On the contrary, during the first post-prandial 30-min period, post-prandial MI was significantly reduced (p<0.003, ANOVA) in patients with migraine (13.4±4.8 mL x min) than in HV (19.6±6.9 mL x min) and in dyspeptic patients (22.6±7.4 mL x min).

**Conclusions**

Our results show that patients with migraine and dyspeptic symptoms suffer from an alteration of post-prandial gastric sensorimotor function. In addition to the previously shown post-prandial hypersensitivity, a reduction of post-prandial MI is also present.

**EPIGONE MIGRAINE VERTIGO (EMV): A LATE MIGRAINE EQUIVALENT**

1. Pagnini, L. Verrecchia, B. Giannoni, P. Vannucchi, F. De Cesaris, E. Del Bene

Introduction
The term Migrainous Vertigo (MV) [1] describes all the vertiginous and postural disturbances that are variably expressed by migraineur patients. In 1988, Pagnini [2] proposed a classification of the vestibular symptoms in migraine using a specific criterion: the temporal relationship between headache and vertigo. According to this classification we can find two large groups of MV: the associated and the equivalent. The first represents the vestibular disorder that adds to headache. The second represents the vestibular crisis that substitutes the single spell of headache. The equivalent form can occur before the onset of headaches (precocious equivalent). It could appear during the headache period (intercritical equivalent), or it can develop after the headache ceases (epigone equivalent). This study concerns the latter form.

Subjects and methods
In a clinical observation of 13 years at the Audiology Clinic of the University of Florence, we studied 28 migraineur patients with some features of recurrent vestibular disorders: they suffered from late vertigo with onset only after headache had ceased; their vertigo was not specific for other recurrent oto-neuro-ophthalmological symptoms; there were no specific radiological signs or blood risk factors. With a follow-up at least of two years, we studied this patient group with audiovestibular and neurological examinations and imaging, focusing on the characteristics of headache and vertigo and how they interchanged between each other.

Results and discussion
Females represented 82% of the study group, mean age of headache onset was 18 years and for vertigo was 38 years. Migraine without aura was present in 78% of patients, kinetosis in 78%. The vertigo described by the patients was variable: 64% of patients referred exclusively rotary crises (mean duration 15 hours); 14% described dizziness or postural instability (mean duration 73 hours); 22% suffered from a combination of these features. The headache passed to vertigo with a free interval in 26% of patients. A period of alternation of headache and vertigo was present in 29% of patients. In 45% of patients headache passed directly into vertigo. There were no specific signs from audiovestibular examination during intercritical periods, but in 36% we found a vestibular hyperreffectivity during stimulation. We saw a specific highly repetitive behaviour for this new entity: the response to migraine prophylaxis. Vertigo improved in all patients, furthermore, full recovery from vestibular symptoms was obtained in 68% of patients.

Conclusions
With this clinical observational study, we attempted to characterize a new clinical picture of migraine, the epigone migrainous vertigo, which should be considered when considering vertigo in migraine.

MUSCLE TENDERNESS IN CRANIOMANDIBULAR AND CERVICAL REGIONS AND PSYCHOMETRIC CORRELATES IN A POPULATION OF MIGRAINE PATIENTS WITH AND WITHOUT CHRONIC TENSION-TYPE HEADACHE AND HEALTHY CONTROLS

1V. D’Angiò, 2G. Bruti, 3A. Rivaroli, 4G. Fiocco, 4F. Fatapposta, 1P. Cascone, 5G. Juanti, 6R. Cerbo
1Department of Neurology and Ear, Nose and Throat Specialist, 2Headache Section, 3Oromaxillo-facial Pain Section of the Pain Centre “Enzo Borzomati”, Policlinico Umberto I, University of Rome “La Sapienza”, Rome, Italy; e-mail: gianluca.bru@uniroma1.it

Background A relationship has been shown between pericranial muscle tenderness and psychiatric disorders in migraine patients. In particular, this association has been observed in patients with both migraine and chronic tension-type headache (CTTH).

Objective The aim of the study was: 1) to evaluate the function of the temporomandibular system and of the cervical spine in a population of migraineurs with and without CTTH; 2) to evaluate the relationship between muscle tenderness, personality profile and psychiatric symptoms in migraine patients with and without CTTH.

Materials and methods Migraineurs with and without CTTH were consecutively recruited according to IHS criteria (ICHD-II). A healthy control group was also recruited. All subjects of the study were submitted to: 1) clinical investigation of the temporomandibular system according to the “Craniomandibular Index” (CMI); 2) pericranial muscle evaluation according to “Total Tenderness Score” (TTS); 3) physical examination of the cervical spine (PECS); and 4) electrognathography (EGG) of the temporomandibular joint. As regards personality profile and psychiatric symptoms, the following tests were administered: Tridimensional Personality Questionnaire (TPQ), Toronto Alexithymia Scale – 20 items (TAS-20), State and Trait Anxiety Inventory (STAI-1-2), and Beck Depression Inventory (BDI). All migraineurs underwent Migraine Disability Assessment (MIDAS) and Headache Impact Test – 6 items (HIT-6) for evaluation of migraine disability.

Results Forty-two migraineurs (mean age 35±10 years), 35 migraineurs with CTTH (mean age 34±12 years) and 32 healthy controls (mean age 32±11 years) were admitted to the study. All migraineurs showed significantly higher scores in CMI, TTS and PECS than healthy controls (p<0.05). Comparing EGG data between migraineurs and healthy controls, we observed in the migraine population a reduction of mandibular movement associated with muscle rigidity (p<0.05). In regard to the psychometric data, migraineurs showed higher scores in BDI and STAI. Harm Avoidance dimension of the TPQ and TAS-20 than healthy controls (p<0.05). All clinical and psychometric findings cited above were more evident in migraineurs with CTTH than those without (p<0.05). Duration of illness, frequency of attacks as well as MIDAS and HIT-6 scores were positively correlated with the total number of cranio-mandibular and cervical tenderness points (p<0.05).

Conclusions Migraine patients present subclinical temporomandibular and cervical spine disorders. These clinical findings are more evident in migraineurs with CTTH and are associated with psychiatric symptoms and with a peculiar personality profile. It might be important to identify these clinical features not only for the therapeutic implications but also to prevent and understand the pathophysiological mechanisms that may lead to chronic migraine.

MIGRAINE AS PRESENTING SYMPTOM OF CEREBRAL AUTOSOMAL DOMINANT ARTERIOPATHY WITH SUBCORTICAL INFARCTS AND LEUKOENCEPHALOPATHY (CADASIL)

1C. Sarti, 2F. Pescini, 4V. Palumbo, 1A. Poggesi, 3S. Bianchi, 5M.T. Dotti, 2A. Federico, 2D. Inzitari, 1L. Panniti
1Department of Neurological and Psychiatric Sciences, University of Florence, Florence, Italy; 2Department of Neurological and Behavioural Sciences, University of Siena, Siena, Italy; e-mail: panniti@unifi.it

Background CADASIL is an inherited (autosomal dominant) vascular disease clinically characterized by recurrent transient ischemic attacks and/or strokes, migraine, mood disorders, cognitive impairment, and seizures. Radiological hallmarks are diffuse white matter abnormalities and/or lacunar infarcts visible on MRI or CT. Genetic mutations are located on chromosome 19p13.1 on the Notch3 gene. Migraine is the symptom of onset of the disease in 40% of cases [1] and has been described in up to 77% of patients in the advanced phase of the disease. Migraine with aura has been reported in up to 40% of cases. About 30% of patients have atypical aura, and atypical plus typical aura has been described in 27% of cases [2].

Methods We describe the clinical characteristics of 14 consecutive CADASIL patients (5 males) belonging to 9 unrelated families.

Results The time of the first neurological evaluation was at an advanced age (mean 51±15 years). Onset of the disease was retrospectively judged to be earlier (mean age 29 years±16) with migraine as the presentation symptom in 64% of patients. On presentation no patient had migraine with aura. Migraine was present in 86% of patients in the advanced phase of the disease. Three patients (21%) had migraine with aura, 2 of them (14%) had typical and prolonged aura. The other clinical features were TIA/strokes (57%), cognitive deficits (71%), and mood disturbances (79%).

All patients presented confluent or partly-confluent MRI white matter changes with the exception of 2 young patients (26 and 28 years) clinically characterized by isolated migraine. Involvement of the temporal lobes was variable in terms of severity. Family history was positive for at least one CADASIL clinical hallmark in all cases. Notch3 mutations involved exon 11 (3 families), 19 (2 families), and exons 3, 4, 6, and 10 in one family each.

Conclusions CADASIL appears to be an underestimated disease. The phenotypic spectrum is variable ranging from pauci-symptomatic cases to severe disease. Migraine is frequently the earliest symptom of the disease occurring at a relatively young age. CADASIL should be suspected in patients with migraine who have MRI white matter alterations of moderate to severe degree and a positive family history for at least one clinical hallmark of the disease.

PRIMARY CHRONIC HEADACHES IN ITALY: ANALYSIS OF DIAGNOSES WITH THE AID OF A DEDICATED SOFTWARE BASED ON ICHD-II CRITERIA

A. Baldi, F. Coppola, I. Corbelli, M.L. Mancini, C. Rossi, P. Calabresi, P. Sarchielli
Headache Centre, Neurologic Clinic, Department of Medical Surgical Specialties and Public Health, University of Perugia, Perugia, Italy; e-mail: baldianto@libero.it

Background We recently developed a software, the Primary Headaches Analyser 1.0 INT (PHA), to analyse the clinical data from patients affected by primary headaches [1]. This programme is based exclusively on the International Classification of Headache Disorders 2nd edition (ICHD-II) criteria [2]. This software examines all the diagnoses of primary headaches on the basis of the variables needed to fulfil these mandatory criteria.

Methods We tested the diagnoses of chronic primary headaches with the aid of the software PHA, by entering and analyzing data reported in the clinical chart and headache diaries from 200 consecutive patients affected by chronic headaches and evaluating the corresponding output diagnoses.
Results The diagnosis of 1.5.1 Chronic migraine was obtained in 68 cases (34%), and that of probable 1.6.5 Chronic migraine + 8.2.8 Probable medication-overuse headache in 46 (23%). 2.3 Chronic tension-type headache and 2.4.3 Probable chronic tension-type headache + 8.2.8 Probable medication-overuse headache were diagnosed in 24 (12%), and 2 (1%) patients, respectively. Probable medication-overuse headache (n=46) included combination analgesics (n=12), analgesics (n=11), triptans (n=9), a combination of acute medications (n=7), opioids (n=4), and ergot derivatives (n=3). In the two patients with a diagnosis of 2.4.3 Probable chronic tension-type headache + 8.2.8 Probable medication-overuse headache, combination analgesics were responsible for medication overuse. Moreover, 4 and 12 patients, respectively, received both the diagnosis of 1.5.1 Chronic migraine +2.3 Chronic tension-type headache and of 1.6.1 Probable migraine without aura +2.3 Chronic tension-type headache. In the remaining 44 cases (22%), none of the chronic primary headaches defined by ICHD-II were given as an output diagnosis by our software. This was mainly due to the fact that insufficient criteria were fulfilled for the diagnoses of 1.1 Migraine without aura + 1.5.1 Chronic migraine or, more infrequently, 2.3 Chronic tension-type headache.

Output diagnoses included 1.1 Migraine without aura, 1.6.1 Probable migraine without aura, 2.4.1 Probable infrequent episodic tension-type headache + 2.4.2 Probable frequent episodic tension-type headache, and 14.1 Headache not elsewhere classified. None of the patients whose clinical sheets were examined received a diagnosis of 4.7 Hemicrania continua or 4.8 New daily-persistent headache.

Conclusions Our software (PHA) allowed the diagnoses of chronic migraine or chronic tension-type headache or their probable forms in the case of medication overuse in 78% of the patients with more than 15 days per month examined. In the remaining cases, the inability to provide the above diagnoses can be explained in about one quarter of cases by the fact that the mandatory criteria for both diagnoses are too stringent and do not reflect modifications of the headache patterns in these chronic forms.

DISABILITY AND CHRONIC DAILY HEADACHES: WHO-DAS II VERSUS OTHER SPECIFIC AND NON SPECIFIC DISABILITY TOOLS

Clinical Characteristics of Medication-Overuse Headache

Introduction The International Classification of Headache Disorders (ICHD-II, 2004) remarkably modified the diagnostic criteria of medication-overuse headache (MOH), and also proposed clinical criteria to differentiate headache between different overused medications. Subsequently, these clinical criteria were excluded in the revision of the International Headache Seminar held in Copenhagen in March 2004, due to lack of reliable data from the literature.

Objective The aim of the present study was to analyse, for the first time in a systematic way, the clinical characteristics of headache in a sample of patients suffering from MOH.

Patients and methods We studied 51 patients with chronic daily headache who took analgesics ≥ once per day for more than three months, and were treated for detoxification as in-patients. The study included 46 women (90.2%) and 5 men (9.8%), with a mean age of 53 (SD 12) years. The patients were divided according to the medication overused. The quality, the site, the severity, and the accompanying phenomena were evaluated, taking into account also the characteristics of the pre-existing headache and the response to the medication used. The data were analysed using the Statistical Package for the Social Sciences (SPSS 12.0).

Results The overused medications were: combination analgesics in 20 patients (39.2%), simple analgesics in 17 patients (33.3%), triptans in 10 patients (19.6%), and ergotamine in 4 patients (7.8%). The more common pre-existing headache was migraine without aura (39 patients, 76.5%). The pain was more frequently pulsating (28 patients, 54.9%), bilateral (29 patients, 56.9%), and of severe intensity (34 patients, 66.7%). Accompanying phenomena were present in 43 patients, Italian version. Headache diagnosis was made according to ICHD-II criteria [2]. No patient had taken prophylactic medications for headache during the 6 months preceding the observation. Statistical analysis included partial correlation tests between items of the three instruments and alfa Cronbach parameter for evaluation of WHO-DAS II internal consistency.

Discussion and conclusions The above findings show that WHO-DAS II is comparable to SF-36 and HIT-6 as a tool for disability measurement. No correlations were found between WHO-DAS II items and headache clinical features, such as disease duration or duration of analgesic overuse. Some SF-36 items, instead, showed a statistically significant correlation with duration of illness, but not with the duration of analgesic overuse. To identify internal consistency between all items of WHO-DAS II, we used alfa Cronbach parameter. Its value was between 0.8 and 0.9 for all domains analysed indicating a high internal consistency, which supports the use of WHO-DAS II as a sensitive instrument for detecting disability in headache patients. In particular, it may prove to be a valuable measurement tool for disability in chronic headache patients, and it could be useful for indicating effectiveness of therapy and guiding clinical management in these patients.

CLINICAL CHARACTERISTICS OF MEDICATION-OVERUSE HEADACHE

G. Relja, A. Granato, M. Zorzon, Z. Bisin, G. Nider, G. Pizzolato
Department of Clinical Medicine and Neurology, Headache Centre, University of Trieste, Trieste, Italy; e-mail: antonio.granato@hotmail.com
The headache in this sample of patients with MOH was more frequently pulsating, bilateral, severe and associated with nausea and phonophobia and photophobia. The clinical characteristics were not different according to the various types of overused medications, supporting the revision of the International Headache Seminar of Copenhagen (2004). The pre-existing headache and the response to overused medications did not influence the characteristics of MOH.

**SUICIDE RISK IN CHRONIC DAILY HEADACHE**

S. de Filippis, E. Salvatori, E. Nittoli, G. Coloprisco, I. Farinelli, P. Martelloni

University of Rome “La Sapienza”, II School of Medicine, Regional Referral Headache Centre, Sant’Andrea Hospital, Rome, Italy; e-mail: grazia.sances@mondino.it

In the Western world, 2%–4% of deaths are due to suicide, incidents and murders. Suicide is experienced as a predictable, and therefore preventable death; its occurrence causes a sense of anguish in relatives and frustration and impotence in physicians. Chronic somatic pathologies, such as diabetes, cardiopathy, cancer, stroke and correlated problems like pain, weight loss, insomnia etc. increase vulnerability and predispose to the risk of suicide. Our aim in this study was to evaluate the presence of both humoral disorders and suicide risk in 300 patients affected by chronic daily headache and medication-overuse headache, who were observed for 24 months in our Centre.

We based our work relying upon interviews, collection of anamnestic data related to the premorbid period, information given by patients concerning the sufferers’ behaviour during the day, attitudes towards others, maintaining of previous interests, and modifications of the biological rhythm.

Moreover, psychometric tests were administered, revealing a remarkable correlation between humoral disorders and headache, impairment of working activity, relationships and family life. Through structured interviews with patients and family, the presence of both depressive symptomatology and suicide ideation before the appearance of chronic daily headache has been evaluated.

Finally, our purpose was also to establish if, unlike other pathologies, suicide risk was high or remained just intentional.

Preliminary data indicate 42 patients (21%) with positive results; more specific tests (SSI, BRFL) were performed in order to quantify the importance, intensity and pervasiveness of suicide ideation.

### Case Reports

#### DIFFICULTIES IN MIGRALEPSY DIAGNOSIS: A CASE REPORT

G. Sances, N. Ghiotto, E. Giusachino, M. Loi, N. Arce Leal, F. Balsamo, R. Manni, G. Nappi

1Department of Mental Health, A.S. 6, Lamezia Terme, Italy; e-mail: rosarioiann@tiscali.it

Migraine and epilepsy are paroxysmal disorders showing clinical and epidemiological comorbidity whose possible relationship remains to be clarified. When a seizure begins during or close to post-aura symptoms, we refer to migralepsy. This phenomenon is described in subjects suffering from migraine with aura; the ICHD-II (2004) diagnostic criteria codify this new entity at 1.5.5 (in the chapter on migraine). A 36-year-old man was referred to our headache centre with aura symptoms. The patient’s history (birth, physiological history and psycho-physical development) was normal. His history of migraine (without aura and showing a weekend pattern) started at age 20. At 34, he began experiencing frequent visual bilateral symptoms lasting 10 minutes and never followed by headache (12 episodes/month). These occurred, in particular, in the evening, after work. He described flashing lights, diffuse in the visual hemifield on the headache side, lasting 5–10 minutes. He also recalled two episodes of déjà-vu symptoms associated with nausea. At age 36, he reported an episode of his typical visual symptoms associated with a déjà-vu perception, perception of a “clean” smell (of fresh laundry), and nausea, lasting about 10 minutes. He then lost consciousness, fell to the ground, and displayed tonic seizure of the limbs with laceration of the tongue. After about five minutes, he resumed normal respiration, but remained rather unresponsive and confused until the arrival of rescue workers. Apparently, this episode was not followed by headache. MRI and basal EEG were normal, whereas sleep deprivation EEG showed a diffuse and large theta frequency in the left cerebral hemisphere. The diagnosis was tonic seizure in migraine with/without aura. The patient began treatment with topiramate (200 mg daily).

Finally, our purpose was also to establish if, unlike other pathologies, suicide risk was high or remained just intentional.

Preliminary data indicate 42 patients (21%) with positive results; more specific tests (SSI, BRFL) were performed in order to quantify the importance, intensity and pervasiveness of suicide ideation.

#### ACUTE MANIA INDUCED DURING A CLUSTER HEADACHE EPISODE: A CASE REPORT

G. Coloprisco, M. Gallo, M.A. Massimo, E. De Caro

1Regional Headache Centre, “Pugliese-Ciaccio” Hospital, Catanzaro, Italy; 2Department of Mental Health, A.S. 6, Lamezia Terme, Italy; e-mail: rosarioiann@tiscali.it

Background Cluster headache often leads to mood changes in patients, in particular, to depressive reactions and sometimes to suicide. However, there are no controlled studies on the comorbidity of cluster headache and affective disorders such as manic-depressive illness. We report on a patient who developed his first manic episode while suffering from a cluster episode.

Case report A 34-year-old male patient has been suffering from episodic cluster headache according to IHS criteria for 8 years. He experienced one cluster episode per year with a duration of about 2 months. The left-sided cluster attacks occurred about 4 times a day with a single duration of about half an hour. Oxygen inhalation, and subcutaneous sumatriptan promptly aborted an attack. In recent episodes, verapamil at a dosage of 360 and 480 mg per day was effective as prophylactic agent. At the beginning of his last cluster episode, he received steroids from his general practitioner at a daily dosage of 125 mg per week, which progressively decreased. At first the attacks stopped, but then reoccurred after 10 days; thus the patient was
admitted to our Headache Centre. However, a few days later, while still under steroids, the patient rapidly developed manic symptoms and had to be admitted to a psychiatric isolation ward. Treatment with quetiapine 300–600 mg per day was started, and after 10 days the manic symptoms disappeared; cluster attacks occurred occasionally under this monotherapy.

Conclusions To our knowledge, this is the first report on the onset of manic symptoms during a cluster episode. Since the patient had some endogenous depressive episodes in the past, the diagnosis of manic-depressive illness was made according to the International Classification of Disease, 10th edition (ICD-10). The manic episodes were probably induced by steroids or by steroid withdrawal. We conclude that cluster headache patients with a history of affective diseases should not be treated with steroids but with quetiapine or lithium, which are effective in both conditions.

HYPNIC HEADACHE WITH A SPORADIC PATTERN

F. Mainardi,1 C. Lisotto,1 F. Maggioni,1 F. Paladin,1 G. Zanchin1
1Headache Centre, Neurological Unit, SS Giovanni and Paolo Hospital, Venice, Italy; 2Headache Unit, San Vito al Tagliamento Hospital, San Vito al Tagliamento, Pordenone, Italy; 3Headache Centre, Department of Neurosciences, University of Padua, Padua, Italy; e-mail: fnainardi@iol.it

Hypnic headache (HH) is a primary headache disorder, classified in the fourth chapter of ICHD-II, which occurs exclusively during sleep and usually begins after the age of 60 years [1]. The natural evolution of HH is not well known, but it is assumed that it tends to be chronic unremitting. A follow-up of at least 2 years is described for only 25 patients among the 85 cases reported in the literature; according to the outcome data obtained from these patients, we recently proposed to distinguish between chronic and episodic HH [2].

A 63-year-old woman complained of a dull, severe headache in the vertex, which developed only during sleep and awakened the patient, without any accompanying signs or symptoms; the headache completely resolved 30 minutes after awakening. She referred the first episode two years before our visit and its recurrence with a very low rate (one attack every six months, for a total of four episodes, the last one just before the observation). Due to the short duration of the attack, the patient did not take any drug. A detailed interview revealed the presence of two more forms of primary headache (migraine without aura and infrequent episodic tension-type headache). General and neurological examinations, laboratory tests, and brain MRI with gadolinium were normal.

To our knowledge, this is the first case of a headache fulfilling ICHD-II criteria for HH with an infrequent pattern, and it supports our previous observations regarding the possibility of an episodic evolution of this rare primary headache.

PRIMARY STABBING HEADACHE IN THE ELDERLY: A CASE REPORT

F. Mainardi,1 F. Daunese,2 P. Pagan,1 C. Palestini,1 F. Paladin,1 G. Zanchin1
1Headache Centre, Neurological Unit, 2Radiology Department, SS Giovanni and Paolo Hospital, Venice, Italy; 3Department of Medicine, Adria Hospital, Adria, Rovigo, Italy; 4Headache Centre, Department of Neurosciences, University of Padua, Padua, Italy; e-mail: fnainardi@iol.it

We present the case of a 74-year-old man referred because of the onset in the previous month of a severe head pain occurring as a series of stabs (generally 3–5) in the left parietal area, lasting up to two seconds and recurring with irregular frequency without any accompanying signs or symptoms. He never experienced a recurrent headache before. The pain occurred every hour during the morning, and two or three times in the afternoon. The stabs presented with an average frequency of four days per week. His medical history revealed the presence of ischemic heart disease with atrial fibrillation and hypertension. Because of his heart condition, a cardiac pacemaker was implanted and he regularly took anticoagulants and hypotensive drugs. The general and neurological investigations were normal. A brain CT scan with contrast medium revealed no alteration; it was not possible to perform a brain MRI because of the presence of the heart pacemaker. We suggested indomethacin at the dose of 50 mg daily. From the second day of therapy the stabs disappeared. He is still headache-free after 3 months of follow-up.

Primary stabbing headache is classified in ICHD-II within chapter 4 “Other Primary Headaches”. The short-lasting duration and the irregularity of its frequency justify the low rate of consultation, despite the relative diffusion of the condition, which occurs in 35% of the general population, according to recent data. In the same population-based study, the peak was reached in the third decade; the onset in the elderly is rarely reported [1].

The peculiarities of our case are: i) the sudden onset in the elderly; ii) the prompt response to low indomethacin dose. Further studies are warranted to better specify the diagnostic criteria for this form of primary headache and its treatment.

A MIGRAINE-LIKE HEADACHE

F. Mainardi,1 M. Trucco,1 A. Campioni,1 F. Maggioni,1 F. Paladin,1 G. Zanchin1
1Headache Centre, Neurological Unit, SS Giovanni and Paolo Hospital, Venice, Italy; 2Headache Unit, Neurological Division, Santa Corona Hospital, Pietra Ligure, Italy; 3Headache Centre, Department of Neurosciences, University of Padua, Padua, Italy; e-mail: fnainardi@iol.it

The cornerstone of migraine diagnosis, in the absence of pathognomonic biological or imaging markers, are the anamnestic data, with particular regard to the clinical features of the headache, and the general and neurological examinations. Neuroimaging or laboratory tests are useful to exclude a secondary origin, when: i. the characteristics of the headache do not fulfil ICHD-II criteria for the diagnosis of migraine; ii. the general or neurological examinations are abnormal; iii. the anamnestic data show the presence of alarm features, the so-called red flags. A 37-year-old woman presented with a one-month history of daily, severe, diffuse headache with phonophobia, photophobia, nausea, and vomiting. She attributed these symptoms to migraine, a condition she suffered from since her twenties with an average frequency of 2 attacks per month. She decided to undergo a medical consultation because of the lack of response to the usual therapy (tripants and NSAIDs) and the progressive worsening of the symptoms. General and neurological examinations did not reveal any abnormalities. A brain CT scan showed the presence of several metastases in both hemispheres with a dislocation of the mid-line structures. Further investigations demonstrated a primary ovarian neoplasm. The patient died two months later. The possibility of a secondary origin was suggested by the accelerating pattern of a previous well-known headache and the lack of response to treatment, both of them to be considered as red flags. The peculiarity of this case is essentially represented by the normal general and neurological examinations despite the dramatic neuroimaging picture.
Secondary headaches fulfilling ICHD-II criteria for the diagnosis of a primary headache are described also for other forms (e.g. cluster headache, TACs) [1–2]. The adherence to major TACs ICHD-II criteria and a normal general and neurological visit are necessary, but not sufficient to exclude a secondary process. Thus, the appearance of a “red flag” in a headache patient should always prompt a re-evaluation to exclude the presence of a secondary cause.

TRIPTAN OVERUSE AND EPISODIC SEROTONIN SYNDROME
1F. Mainardi, 2A. Palmieri, 1F. Daines, 1C. Lisotto, 1F. Paladin, 4G. Zanchin
1Headache Centre, Neurological Unit, SS Giovanni and Paolo Hospital, Venice, Italy; 2Headache Unit, Service of Neurology, Hospital of San Donà di Piave, San Donà di Piave, Venice, Italy; 3Headache Unit, San Vito al Tagliamento Hospital, San Vito al Tagliamento, Pordenone, Italy; 4Headache Centre, Department of Neurosciences, University of Padua, Padua, Italy; e-mail: fmainardi@iol.it

Serotonin syndrome (SS) is a rare pathological condition related to the concomitant use of drugs that increase 5-HT availability; the pathophysiology of SS seems to be ascribed to the stimulation in the brain-stem of 5-HT1A receptors and the inhibition of 5-HT1A dopaminergic transmission, secondary to serotonergic hyperactivity. SS includes several neurological and autonomic manifestations that follow administration or an increased dosage of serotonergic drugs, and is clinically defined in the presence of at least three of the following signs/symptoms: mental status changes, myoclonus, hyperreflexia, tremor, fever, diaphoresis, shivering, and diarrhoea [1]. Because of their actions, triptans have been implicated in the pathogenesis of SS, in particular, if taken with drugs which increase 5-HT levels. We describe the case of a 61-year-old woman, who presented at a first visit a headache fulfilling ICHD-II criteria for probable chronic migraine without aura and probable triptan overuse headache. She treated her attacks with triptans, taking an average 29–30 doses per month for at least 6 months; sometimes (once a week) she had to take triptans twice daily. Furthermore, she took mirtazapine 30 mg/day for a depressive syndrome. She referred episodes of intense sweating, mental confusion, shiver, tremor, and inconstant diarrhoea, lasting 3–4 hours and leaving her prostrate. She complained of such episodes a few hours after taking a second dose of triptan. She first reported these symptoms five months before our observation, but she attributed them to her depressive status. Symptoms disappeared after the withdrawal of mirtazapine and a detoxifying treatment (follow-up 3 months), whereas the headache frequency remained unchanged; therefore, the final diagnosis was chronic migraine without aura.

The peculiarities of this case are: i. the temporal pattern and the spontaneous remission of each episode, indicating a recurrent and mild form of SS; ii. the correlation between taking a double dose of triptans and the onset of SS symptoms, documented by a diary; iii. the concomitant use of mirtazapine, a drug rarely implicated in generating this syndrome.

CONTRIBUTION OF NEUROBIOLOGICAL AND PSYCHOLOGICAL TRAITS IN MEDICATION-OVERUSE HEADACHE (MOH) DEVELOPMENT: A CASE REPORT
1V. Rispoli, 2R. Iannachero, 3E. De Caro

1Department of Pharmacobiological Science University “Magna Graecia” of Catanzaro, Catanzaro, Italy; 2Regional Headache Centre, “Pugliese-Ciaccio” Hospital, Catanzaro, Italy; e-mail: rispoli@unicz.it

Even though it is not yet clear whether the misuse and/or abuse of analgesics or triptans in migraine may be involved in headache chronicity, chronic pain and pain relief are considered the most important features in inducing a habitual behaviour as therapeutic need. It is well known that complex brain areas, as well as different neurotransmitter systems and complex responses participate in the biology of the reward brain system. Comorbidity for psychiatric disorders, such as anxiety and depression, as well as negative life events, exacerbate headache and quality of life in patients suffering from headache [1]. Stressful periods, can induce disruption in these internerval interactions and result in a craving for drugs to relieve the pain and bad feelings. Serotonin plays an important role in migraine pathogenesis, and drugs such as triptans, 5-HT1B/1D agonists, are the first choice for acute migraine therapy. Recent findings support the hypothesis that serotonin could contribute to the development of mechanisms underlying the reward system in the brain, inducing a compulsive habit for consumption of antimigraine analgesics [2]. The present paper would like to contribute to clarifying the above described mechanisms. For this purpose, a case report is introduced and discussed.

A 45-year-old woman complained of primary migraine for many years. The headache occurred two, sometimes three times a week. Prodromic symptoms, such as tension in the orbital region and nausea, preceded the headache. For about two years, the patient abused of analgesics (NSAIDs), and during the last year she took triptans (9 to 10 times a month during the last three months) and analgesics. Despite the drug treatment, headache recurred more frequently, and the characteristics of the pain changed, from being sharp and starting abruptly to often presenting in one hemiscape and spreading subsequently to the entire head. The clinical story of the patient revealed psychiatric co-morbid disorders for anxiety and depression following a stressful period for job-related problems (mobbing?). A genetic study was carried out to investigate inherited predisposition to thrombophilia and verify the possibility of sinus venous thrombosis. A Factor V gene mutation was found. Moreover, neuroimaging investigations (MRI and intracranial venous MR angiography) did not show any pathological brain conditions but revealed a dominant dilated and tortuous right transverse sinus, whereas the left transverse sinus was hypeplastic. During hospitalization, drug treatment was stopped and prophylactic therapy was started.

In conclusion, this case report suggests that headache chronicity might be caused by biological as well as psychological traits. Correct management of migraine and headaches may contribute to modifying habitual behaviour and reducing consumption of drugs in chronic sufferers.

A CASE OF UNSATISFACTORY HEADACHE MANAGEMENT SUPPORTING THE NEED FOR INFORMATION AND EDUCATION ABOUT HEADACHE DISORDERS
E. Tasciotti, B. Cappa, D. Camatoni, M. Evangelista
Institute of Anaesthesitics, Intensive Care and Pain Therapy, Catholic University “Sacro Cuore”, Rome, Italy; e-mail: edotasciotti@hotmail.com

Introduction
With this case report we want to emphasize how important it is, and how much work still needs to be carried out in terms of patient education and divulgation of information about headaches.
Case A 41-year-old man suffered from headache (the first episode occurred about 15 years ago). This affection became worse in frequency, intensity and refractory to the rescue dose in the last 12 months, compromising his job. The characteristics of this headache were: daily frequency, right-sided localization, beginning in the posterior region of the head, absence of aura except for tension located in the cervico-occipital area over the paravertebral muscles, associated with pain in the point of emergency of Arnold’s nerve; bi-laterally lasting ≥24 hours. Pain intensity was measured with Visual Analogue Scale (VAS). Phonophobia and photophobia were so strong during the crises that they forced the patient to abandon his activity. Under prescription, the patient had taken 500 mg effervescent tablet as rescue dose. Consecutively, because the headaches did not resolve, he took 10 mg of rizatriptan RPD, which he defined has being unsatisfactory for pain relief. The patient did not receive any information about the rescue dose nor prophylactic drugs from the previous doctors, even though he had been suffering from headache for the past 15 years and was experiencing increased headache frequency.

The patient underwent algological examination: finger pressure caused pain at the paravertebral cervical muscles conserving flex extension and laterality of the first trigeminal branch. The trigger point was on the right trapezoidal muscle.

Chronic sinusitis was found in the patient, who worked in an area subject to climatic variations. He was allergic to acetylsalicylic acid. Instrumental diagnosis, x-rays of the head and cervical spine in two separate moments (23/02/06), showed a reduction of physiological cervical lordosis, which resulted in osteoarthritis. The patient was prescribed the following therapy: Fluxartan 5 mg at 9 p.m. Laroxyl 5 mg gtt at 9 p.m. Sirdalud 1/2 tablet bid

Rizatriptan RPD 10 mg s.i., when needed. Therapeutic efficacy was and is still being evaluated monthly by VAS.

Results The described therapy was followed continuously considering the high tolerability of the prophylactic drugs. After 4 weeks, the monthly frequency of crisis decreased to three, with VAS=7 and the patient responded to rizatriptan taken at the beginning of the crisis. After 8 weeks, the frequency decreased to 2 crises, VAS=5, and the patient responded to rescue dose. Currently, the patient is drug free and refers two headache crises per month. He has returned to work and now considers his social life normal.

Conclusions This case represents the paradigm of an incorrect treatment for headache symptoms, regarding both the most suitable strategy to use and when to take the symptomatic drug. It is evident how a symptomatic strategy for daily headache exposed the patient to drug overuse and to an unsuccessful therapy causing social and working problems. It should be mentioned that the lack/absence of correct information regarding early prophylaxis also contributed to the unsuccessful resolution of headache pain.

HEMIPLEGIC MIGRAINE WITH PROLONGED SYMPTOMS IN ATYPICAL STURGE-WEBER SYNDROME

M.A. Tavoni, N. Zamponi, E. Cesaroni, L. Poffati, C. Cardinali Riuniti University Hospitals, Paediatric Neurology Department, Children’s Hospital “G. Salesi”, Ancona, Italy; e-mail: npisalesi@ao-salesi.marche.it

Introduction The Sturge-Weber Syndrome (SWS) is a rare disease characterized by an encephalotrigeminal or leptomeningeal angiomatosis and facial vascular nevus (port-wine stain). It is part of a phenotypic spectrum, which includes other syndromes with capillary angiomatosis malformations in various sites, such as Klippel Trenaunay Weber Syndrome with malformations not only of the capillaries, veins, arteries, and lymphatic vessels, but also of soft tissues and bone hypertrophy, obesity, high blood pressure, and epileptic seizures, who presented at 14-years of age with pulsating unilateral headache with visual disorders and acute - prolonged left hemiparesis. None of the episodes were preceded or accompanied by loss of consciousness or ictal tonic jerks. The EEG was normal during the headache episode. MRI showed the typical Sturge-Weber angiomatosis without ischemic lesions.

Results and discussion Our case report suggests a Sturge-Weber atypical syndrome that could be responsible for symptomatic migraine-like headache. According to criteria of the ICHD-II classification 2004, this syndrome could be clinically diagnosed with probable migraine with aura (subtype 1.6.2) with atypical features. Vasomotor modifications in venous flow in relation with pial angiomatosis are probably at the origin of these migraine-like episodes. Chronic oligoemia and the pre-existent metabolic cortex damage caused by hypoperfusion would worsen the clinical symptomatology [2].

Epileptic seizures between the prodromic and pain phase of migraine attack are rarely reported in paediatric age and in patients affected by SWS. Probably, the migraine attacks, like the seizures, are to be considered another expression of brain damage as a result of microvascular disturbances.

A CASE OF POSTERIOR SCLERITIS: HEADACHE ATTRIBUTED TO OCULAR INFLAMMATORY DISORDER

A case of posterior scleritis is described. Posterior scleritis is an uncommon form of scleral inflammation, which can be confused with several inflammatory and non-inflammatory ocular diseases or ocular tumors. Anterior scleritis can be associated with this condition. It may be idiopathic or associated with systemic disease, particularly connective tissue disorders [1]. In the International Headache Society Classification [2] it is included in the chapter “Headache attributed to ocular inflammatory disorder” (11.3.4). Periorcular pain, pain on movement and decreased vision are the most frequent symptoms [1]. Pain can also be referred to the forehead, maxilla, or sinuses and is described as penetrating in character. Redness of the affected eye can be observed. Ultrasonography is the key investigative necessary to make the diagnosis of posterior scleritis [1]. CT scan and fundus fluorescein angiography can also be used.

Case history We report a case of a 26-year-old woman who began to complain of right-sided ocular and periorcular pain, exacerbated by ocular movements, irradiating to the ipsilateral temple and zygoma, not associated with visual disturbances. Admitted to our Emergency Department, she underwent an ophthalmological consultation, which showed a normal fundus ocular and visual acuity. Trigeminal neuralgia was suspected and she was then treated unsuccessfully with analgesics. Seven days later, she underwent a second ophthalmological and a neurological consultation, which were both normal. After one week, she experienced a worsening of facial pain associated with conjunctival injection, eyelid edema, and developed a central scotoma. She was then admitted to our clinic. Fundus ocular showed in the right eye a hyperemic optic disc with blurred margins. Blurred vision in the right eye with a central scotoma was referred. The remaining neurological examination was normal. A third ophthalmological consultation showed a visual acuity of 1/10 in the right eye (10/10 in the left) with conjuncti-
val injection. Fundus oculi confirmed the above reported findings and some retinal folds; ultrasonography revealed scleral thickening and exudative retinal detachment, suggesting a posterior scleritis. Chest X-ray, routine blood tests, brain MRI with gadolinium and cerebrospinal fluid examination were normal.

The patient was treated with methylprednisolone i.v. 1 g/day for 10 days with complete regression of pain and clear improvement of visual disturbances. Ultrasonography performed 10 days after the end of treatment showed a reduction of scleral thickening, fluid in the Tenon capsule, and regression of retinal detachment. Visual acuity was 6/10 in the right eye. A month after discharge the patient began to complain of left periorcular pain, without visual loss. Ultrasonography showed posterior scleritis in the left eye; she fully recovered after a further course of steroid treatment.

Discussion

Posterior scleritis is a common form of scleritis and should be suspected in patients who present with ocular pain and visual loss. It is one of the most commonly misdiagnosed conditions in ophthalmology, especially when, as in our case, pain is not associated with visual disturbances or ocular signs at the onset of symptoms.

HEADACHE AND ISOLATED PARALYSIS OF THE 12TH CRANIAL NERVE AS A PRESENTING SYMPTOM OF DISSECTION OF THE INTRAPETROSAL TRACT OF THE INTERNAL CAROTID ARTERY

S. Tenaglia, A. Baldi, P. Sarchielli, P. Calabresi

Headache Centre, Neurologic Clinic, Department of Medical Surgical Specialties and Public Health, University of Perugia, Perugia, Italy; e-mail: baldianto@libero.it

Case description

A 60-year-old man came to our attention for the onset of symptomatology characterized by continuous, left-sided, fronto-orbital headache of moderate intensity, associated with photophobia, which did not regress after taking common analgesics. After about three days, the patient presented with a worsening of the headache, which was of stronger intensity and with the appearance of dysphagia and dysarthria.

The neurological examination revealed a deficit of the left XIIth cranial nerve. Brain CT, brain MRI, Echo-colorDoppler of the supra-aortic vessels and the superficial temporal arteries were normal. Cavernous carotid fistulas constitute 20%–40% of all dural AVFs [2], and are formed by an abnormal communication between the carotid artery and cavernous sinus.

Venous hypertension subsequent to shunt formation results in retrograde venous drainage into the ophthalmic venous system, which is responsible for the ocular symptoms, cortical venous reflux, and tendency to haemorrhage.

Headache is rarely a presenting symptom, but when present, it is associated with ophthalmoplegia. The differential diagnosis is with other forms of painful ophthalmoplegia.

Discussion

Carotid artery dissection is an important cause of stroke in the young. Headache and facial pain, often associated with Horner’s syndrome, constitute a common onset symptom and may precede stroke by a few days [1]. Headache associated with deficit of the hypoglossal nerve is not a common onset symptom, and only a few cases are described in the literature [2]. More frequently, this symptomatology may be secondary to diseases of the jugular foramen, and in this case, is associated with paralysis of other cranial nerves (IXth and Xth).

In the case described, brain MRI excluded intracranial diseases. Echo-colorDoppler of the supra-aortic vessels could not visualise the dissection, in that it involved the intrasosseous segment of the internal carotid artery, thus warranting a specific study of the complete intracranial course of this artery.

PAINFUL RECURRENT BILATERAL OPHTHALMOPLEGIA SECONDARY TO BILATERAL CAROTID Cavernous fistula

A. Baldi, F. Coppola, C. Rossi, P. Sarchielli, P. Calabresi

Neurologic Clinic, Department of Medical Surgical Specialties and Public Health, University of Perugia, Perugia, Italy; e-mail: baldianto@libero.it

Case description

A 68-year-old woman presented to us one week after onset of symptoms characterized by a stabbing headache of strong intensity, in the retro-orbital and left fronto-temporal regions, with nausea, photophobia and phonophobia associated with diplopia. The neurological examination revealed paresis of the left VIth cranial nerve, tactile hypoaesthesia, and left-sided pain of the first division of the trigeminal nerve.

Brain CT revealed slight enhancement with gadolinium in the left cavernous sinus. Blood tests, Echo-colorDoppler ultrasound of the supra-aortic vessels and the superficial temporal arteries were normal. The patient was treated with prednisone 50 mg/day for one week and subsequently 25 mg/day. After 48 hours the headache regressed, but the diplopia persisted.

After two months, the patient also presented diplopia on right gaze, eyelid edema, conjunctival injection in the right eye, associated with unilateral retro-orbital pain. The neurological examination revealed: proptosis, eyelid edema, conjunctival chemosis, partial deficit of the right IIIrd cranial nerve, and deficit of the left VIth cranial nerve.

Brain MRI was repeated and in the norm. Subsequently, brain angio-MRI was performed, which revealed a bilateral dural fistula of the cavernous sinuses and the occipital foramen.

The lesion was treated with embolization via the left transjugular approach.

Discussion

Dural arteriovenous fistulas (AVFs) are a rare condition, with a rate of incidence of 0.16 per 100,000 inhabitants/year; with respect to other intracranial vascular malformations they can be acquired, often as a consequence of cerebral venous thrombosis, previous head trauma, aneurysmal rupture, and local and systemic infections [1].

Cavernous carotid fistulas constitute 20%–40% of all dural AVFs [2], and are formed by an abnormal communication between the carotid artery and cavernous sinus. Venous hypertension subsequent to shunt formation results in retrograde venous drainage into the ophthalmic venous system, which is responsible for the ocular symptoms, cortical venous reflux, and tendency to haemorrhage.

Headache is rarely a presenting symptom, but when present, it is associated with ophthalmoplegia. The differential diagnosis is with other forms of painful ophthalmoplegia. Neuroimaging studies are normal or furnish indirect signs (often non-specific) of fistula presence; the only certain diagnostic investigations are brain angio-MRI [1].

In the case of carotid-cavernous fistulas, among the various therapeutic options endovascular embolization is the least invasive method, and when possible, the transvenous access can lead to complete obliteration of the fistula [1].

PAINFUL OPHTHALMOPLEGIA WITH CSF ALTERATIONS: A
CASE REPORT
A. Mercurio, G. Caranci, M. Altieri, V. Di Piero
Headache Centre, Department of Neurological Sciences, University of
Rome “La Sapienza”, Rome, Italy; e-mail: vittorio.dipiero@uniroma1.it

Introduction Painful ophthalmoplegia (PO) is a syndrome character-
ized by the occurrence of periorbital pain and ophthalmopleparesis, with
or without the involvement of other cranial nerves, caused by several
different etiologies.

Case history A 46-year-old man was admitted to our ward, with a
severe dull and steady pain in the right orbit and in the surrounding
area of the forehead, associated a few days later with the appearance of
diplopia and right eyelid ptosis. The neurological examinations showed
a paresis of both the right third and fourth cranial nerves. Physical and
laboratory examinations, trigeminal reflexes, cerebral MRI, arterial
and venous MR angiography were all normal.

A CSF sample showed an elevated protein content (93 mg/dL), with a
positive Pandy reaction and alteration of blood-brain barrier indices,
and was negative for the presence of common infectious agents. Two
days after the clinical admission, the headache disappeared, and the
third and fourth nerve palsy improved significantly, with full recovery
from diplopia a few days later. The increase in CSF proteins persisted
during 2 weeks (73 mg/dL) and 1 month (64 mg/dL).

There were several causes of PO: vascular, inflammatory, infections,
dismetabolisms, neoplasia, trauma, recurrent demyelinizing neu-
ropathy and ophthalmoplegic migraine (OM). OM may be suspect-
et when a severe headache is associated with ophthalmopleparesis, nor-
mal MRI investigations and a benign course [1]. In our case this
diagnosis could be hypothesized. In this regard, it is noteworthy that
the IHS criteria (1988) required a single episode (probably because of
its rarity), while ICHD-II criteria require its recurrence [1]. In our
patient, the CSF abnormalities, the single episode and the “non-
migrainous” features of the headache, except for the severity, are
consistent with an uncommon viral infection. Because OM is more
a syndrome than a specific disease, this case suggests that if a diag-
nosis of OM is suspected, the possibility of a benign inflammatory
disease should be considered, in particular, when ICHD-II criteria
are not fully satisfied [1].

HEADACHE IN A PATIENT WITH CEREBRAL SINUS
THROMBOSIS AND SPONTANEOUS INTRACRANIAL
HYPOTENSION

E. Mampresò, F. Maggioni, A.P. Bartina, C. Perin, F. Mainardi,
G. Zanchin
Headache Centre, Department of Neurosciences, University of Padua,
Padua, Italy; Department of Neurologia, SS Giovanni and
Paolo Hospital, Venice, Italy; e-mail: edoardo.mampresò@unipd.it

Cerebral venous sinus thrombosis (CVST) is an uncommon, life-
threatening condition that mostly affects middle-aged women. The
principal, and also earliest symptom is headache (80%–90%), followed
by other neurological symptoms. The headache has no specific charac-
teristics, is most often diffuse, progressive, severe and associated
with other signs of intracranial hypertension. It can also be unilateral
and sudden, and sometimes mimick migraine, primary thunderclap
headache, cerebrospinal fluid (CSF) hypotension or subarachnoid
haemorrhage (ICH-2004). CVST recognizes a wide variety of risk
factors and causes. In 20%–35% of cases, where aetiology remains
unknown, CVST is classified as idiopathic.

Intracranial hypotension (ICH) syndrome is a very infrequent clinical
condition. Its most common symptoms are orthostatic headache asso-
ciated with nausea and/or vomiting, diplopia, hearing disturbances
(hypoacusia, tinnitus), neck pain, visual deficit and vertigo.

We report the case of a 43-year-old female who presented with
headache, which began three days before, characterised initially by
pressing/tightening, and later on, pulsating quality localised at the
vertex, of mild intensity, without accompanying symptoms, associated with
mild nausea and tinnitus and occurring only on standing. Brain CT scan
showed less evident cortical sulci, small basal cisterns, small ventricular
cavities, without parenchymal alterations. Neurological examination
showed brisk reflexes and bilateral Babinski sign; fundus oculi was nor-
mal. Brain MRI with contrast and angio-MRI showed thrombosis of the
transverse and sigmoid sinuses and of the internal jugular vein on the left
side, along with alterations suggestive of ICH (pachymeningeal contrast
enhancement and Arnold-Chiari-like descent of cerebellar tonsils).

The clinical history was unremarkable, in particular for thromboembolic risk
factors. Complete blood count, thrombophilia tests, and neoplastic
markers were normal, as were ECG, chest X-rays, somatosensory
evoked potentials, and epiarotic vessels and transcranial Echo Doppler.

Spinal MRI with contrast showed signs of CSF leak (deliquoration) in
the dorsal spine. Then, the clinical history was specifically reassessed
and no possible causes of CSF leak were identified. The patient was
referred to the Anticoagulation therapy: an anago-MRI performed 18 days
later showed a partial recanalization. At discharge and at two months
follow-up the patient was asymptomatic.

Cases of CVST in patients with ICH secondary to CSF leak are found in
the literature, but only 4 cases of CVST have been associated with spon-
taneous ICH. Based on these observations, and on our case, it could be
possible that compensatory venous sinus dilution and consequent hemat-
ologic stasis conditions associated with ICH may predispose to CVST.

MIGRAINE WITH VISUAL AURA ASSOCIATED WITH ARTE-
RIOVENOUS MALFORMATION

G. Alberti, A. Giorgetti, G.M. Patruno, A. Romorini
Neurology Service, Magenta Hospital, Milan, Italy; Neurology Unit,
Neurology Department, Legnano Hospital, Legnano, Milan, Italy;
e-mail: alessandro.romorini@ao-legnano.it

Objective To describe two cases of migraine with aura associated with
cerebral arteriovenous malformation (AVM).

Case 1: A 57-year-old woman complained of headache of unusual
severity. She had a history of migraine since age 17, characterized by
an aura of scintillating scotoma for 20–30 minutes on the right side.
Thereafter, a strictly unilateral (left-sided in all cases) throbbing
headache with nausea, vomiting and photophobia occurred. Pain was
mild and responsive to simple analgesics. MRI showed an arteriove-
nous malformation in the left occipital lobe.

Case 2: A 22-year-old woman had a history of migraine since age 15
with visual aura of scotoma and fortification (zig-zag patterns) on the
left side, occasionally accompanied by numbness in the left hand and
face. Her mother had a history of migraine. Three times she had tongue
biting; EEG showed epileptiform discharges. She started valproate
therapy and the visual aura terminated. The aura always occurred on
the left suggesting a possible right-sided structural lesion. MRI showed
a right parietal AVM.

Discussion Arteriovenous malformation is a congenital anomaly that
consists of abnormal arteries and veins without the presence of a cap-
illary bed. The majority of patients initially show intracranial haemor-
rhage, while others may present symptoms of seizures, headaches and
progressive neurological deficits. In the general population, AVMs are
an extremely infrequent cause of headache. Headache occurs in
10%–50% of patients with AVM. The headache may be typical of
migraine. Migraine headaches have a complex pathophysiology, and
(both vascular and neural mechanisms) have been proposed. One
possible scenario begins with brain initiated events evolving to cortical
spreading depression (CSD). Susceptibility to CSD appears to be
generically determined. Structural lesions may cause the initial event.

296
When a patient with migraine manifests symptoms always on the same side, neuroimaging workup is warranted. This should aid in the early diagnosis of cerebral AVM in order to start treatment before the occurrence of cerebral haemorrhage.

TRIGEMINAL NEURALGIA AS PRESENTING SYMPTOM OF ARNOLD CHIARI TYPE I MALFORMATION: A CASE REPORT

G. Caranci, A. Mercurio, M. Altieri, V. Di Piero
Headache Centre, Department of Neurological Sciences, University of Rome “La Sapienza”, Rome, Italy; e-mail: vittorio.dipierro@uniroma1.it

Introduction Clinical presentation of Arnold Chiari type I malformation is highly variable. About 13% of patients are asymptomatic; headache may be the sole clinical manifestation of the malformation; however, it is one of the most frequent. No headache type seems to be particular to the malformation; both short- and long-lasting headaches are described [1].

Case history A 36-year-old woman presented with throbbing-stabbing pain in the left supraorbital region, which started 3 years earlier. Pain occurred three or four times a day; a paroxysmal pain was severe, and lasted 7–10 seconds. There were no warning symptoms; trigger factors were coughing, sneezing, defecation, and nodding movement. There were no accompanying symptoms but mild nausea. Between attacks, she was completely pain-free. She was treated with NSAIDs and carbamazepine without any improvement. Neurological examination and laboratory blood tests were normal. MRI showed an Arnold Chiari type I malformation with downward herniation of the cerebellar tonsils through the foramen magnum into the upper cervical spinal canal. A CT scan of the maxillary and frontal sinuses was normal. Neurosurgical intervention was suggested.

Discussion Our patient satisfied all the criteria for a symptomatic neuralgia probably caused by the Arnold Chiari type I malformation. In this view, we excluded other types of headaches, such as rhinosinusitis, short-lasting unilateral neuralgiform headache attacks with conjunctival injection and tearing (SUNCT), supraorbital neuralgia and idiopathic trigeminal neuralgia. The otolaryngologic examination and CT scan excluded the possibility of rhinosinusitis. Due to the location, duration and frequency of the pain described, it could be compatible with a SUNCT, however, the neurovegetative disturbances, such as conjunctival injection and lacrimation, were absent. Regarding the supraorbital neuralgia, it lacked tenderness over the nerve in the supraorbital notch, and there was no pain in the medial aspect of the forehead in the area supplied by the supraorbital nerve. Unlike trigeminal neuralgia, there were no trigger points, a very rare location only in the first branch, and the lack of any response to high carbamazepine dosage [1].

Conclusions To our knowledge, this is the first case with Arnold Chiari Type I malformation and symptomatic trigeminal neuralgia exclusive-ly in the first branch. It is probable that the pain is caused by an anatomical compression on the trigeminal nucleus, and that the difference in pressure found in the intracranial and intraspinal compartments, evoked by the Valsalva manoeuvre, emphasises this compression, setting off the short-lasting sharp pains [2].

HEADACHE ATTRIBUTED TO BRAIN ABSCESS: A CASE REPORT

A. Giorgetti, M. Conti
1Department of Neurology and 2Department of Neurosurgery, Legnano Hospital, Legnano, Milan, Italy; e-mail: andrea.giorgetti@ao-legnano.it

Brain abscess is a focal suppurative process in the brain parenchyma that still contributes to high mortality rates. Outcome is closely related to correct and early management. In order to evaluate early management, we have reviewed the brain abscesses treated in our Department of Neurosurgery during the last five years, choosing to describe one case among these. We present a 38-year-old male who was admitted to the Emergency Department (ED) complaining of a frontal headache and fever (37.5°C), unresponsive to treatment with NSAIDs. The patient described weakness and numbness of the right limb, which resolved in 20–30 minutes. After CT scan resulted normal, the patient was discharged. The day after, the patient returned to the ED complaining of two new episodes, characterized by weakness and numbness involving the right limb with spontaneous resolution in ten minutes, while an intense, diffuse bilateral headache persisted. The patient was admitted to our department. The neurological examination was unremarkable. However, within five days the patient showed right hemiparesis; the inflammatory index was elevated and MRI revealed a productive, expanding lesion with marked edema in the left parietal region. The modality of treatment was surgical excision with catheter drainage-aspiration of the left parietal abscess. Outcome was excellent: the patient recovered promptly from the hemiparesis, and there was progressive attenuation of headache until it disappeared. Brain abscesses are severe infections with lethal outcome in the case of delay in diagnosis and treatment. Predisposing factors are sepsis of adjacent organs and bacteriaemia. The most frequent clinical manifestations are fever and headache. Headache is usually the most frequently encountered symptom. When under observation our patient continuously complained of bilateral, constant headache with increasing intensity to severe grade, aggravated by straining and accompanied by nausea. A new type of headache associated with general feeling of illness and/or fever should direct attention toward an intracranial infection.

IS THE TREATMENT OF HEADACHE BY SPONTANEOUS CERVICAL CSF LEAK WITH LUMBAR EPIDURAL BLOOD PATCH A RATIONAL CHOICE?

E. Ferrante, I. Arpino, A. Citterio, A. Savino
1Neurosciences and 2Emergency Departments, Niguarda Cà Granda Hospital, Milan, Italy; e-mail: enricoferrante@libero.it

Background Spontaneous intracranial hypotension (SIH) generally results from spinal spontaneous CSF leakage [1]. Treatment is usually conservative. Sometimes an autologous EBP at the site of CSF leakage may be necessary [2].

Objective To evaluate the spread of blood injected into the epidural space during lumbar epidural blood patch (LEBP) for treatment of spontaneous cervical CSF leakage (SCCSFL) by MRI.

Materials and methods We report one case of SCCSFL [among the 32 with this condition evaluated between 1992 and the present].

Results A 45-year-old man presented sudden, intense, gravitative frontal headache. Neurological examination, routine blood tests, and brain CT scan were normal. Brain MRI showed diffuse pachymeningeal enhancement. Gadolinium spinal MRI showed CSF epidural collection from C2 to D3. After one month of bed rest, orthostatic headache was still present. The patient was treated with autologous lumbar EBP (25 mL) at the L2-L3 level. The blood was mixed with 0.05 mL of gadolinium. During and after injection, he remained in the Trendelenburg position (TP) approximately 30° for 1 hour. Spinal post-patch MRI showed gadolinium mixed with blood in the epidural space from the lumbar to cervical level (C2-C3). He subsequently remained in the TP for 22 hours. He was asymptomatic within 24 hours after LEBP. At 6-month follow-up he was asymptomatic.

Discussion and conclusions We demonstrate that EBP, even though injected at the level of the lumbar spine (i.e., far from the site of CSF...

REferred FACIAL PAIN AS A SYMPTOM OF NON-METASTATIC LUNG CANCer: A CASE REPORT AND REVIEW OF THE LITERATURE

A. Palmieri

Headache Unit, Service of Neurology, Hospital of San Donà di Piave, San Donà di Piave, Venice, Italy; e-mail: antonio.palmieri@assili10.veneto.it

Introduction

Facial pain is a common clinical symptom caused by a wide variety of underlying conditions, including neurological, odonto-

Case Report

A 39-year-old woman presented with a 2-month history of pain localized in the left jaw, with extension into the ipsilateral orbit and temple. The pain was continuous, moderate to severe in intensity, and possibly associated with tearing, eye redness, and mild nausea. She had been smoking 1 pack of cigarettes a day, for at least 20 years. An odontological visit, a brain MRI and a carotid Doppler ultrasound were normal. The pain was unresponsive to a number of analgesics as well as carbamazepine, gabapentin, and pregabalin. About 2 weeks before presentation the patient developed cough and poor appetite. The neu-

Discussion

Referred facial pain is a rare symptom of nonmetastatic malignant lung lesions, and was first described by Des Prez and then spontaneously ceased before starting chemotherapy. The

A CASE OF ATYPICAL INTRACTABLE FACIAL PAIN SECONDARY TO METASTATIC LUNG CANCER

S. Ruffatti, F. Maggioni, F. Mainardi, E. Dainese, C. Lisotto, G. Zanchin

Headache Centre, Department of Neuroscience, University of Padua, Padua, Italy; 2Headache Centre, Neurological Unit, SS. Giovanni and Paolo Hospital, Venice, Italy; 3Headache Unit, San Vito al Tagliamento Hospital, San Vito al Tagliamento, Pordenone, Italy; e-mail: silvia.ruffatti@unipd.it

Introduction Persistent idiopathic facial pain is defined by the International Headache Society Classification (ICHD-II) (chapter 13.18.4) as a pain in the face, present daily and persisting for all or most of the day, confined at onset to a limited area on one side of the face, deep and poorly localised. According to the classification, pain around the ear or temple may precede the detection of an ipsilateral lung carcinoma [1]. Nearly 30 cases of intractable facial pain sec-

Case history

A 70-year-old woman presented to the clinic with a 15-

month history of constant, right-sided facial pain, with paroxysms of the upper teeth, irradiating to the auricular and temporal areas. Six months after the onset of pain she underwent CT scan and EEG, which were both normal. She was unsuccessfully treated with amitriptyline (40 mg per day) and gabapentin (up to 2000 mg per day). She had additional complaints of poor appetite with weight loss of 4 kg in the last 6 months and a 9-month history of persistent cough with recent onset of chest pain on the right side. Auscultation of the lungs revealed abnormal breath sounds on the right hemithorax; neurological examination revealed a sensory loss on the right side of the face. Routine blood tests were normal. Chest X-ray revealed a mass in the right hilar region, confirmed by chest CT. She underwent bronchoscopy with lung biopsy; the histological examination revealed pulmonary adenocarcinoma. Brain MRI with gadolinium revealed small multiple supratentorial and infratentorial brain lesions, none of them localized near the right trigem-

Discussion

Facial pain secondary to lung cancer is usually described as a unilateral constant ache, ipsilateral to the lung mass, frequently involving the auricular area, and often associated with signs suggesting a lung cancer (weight loss, digital clubbing, cough, etc.). The pain seems to be due to invasion of the vagus nerve [2]. Our case referred to a metastatic lung cancer, but none of the lesions seen on brain MRI could possibly explain the pain referred by the patient and probably occurred at a distance from the onset of pain. It is important to consid-

Introduction In recent years the quality of medical research in the field of headaches has reached levels of excellence that have amazingly broadened our panorama of knowledge and justified the development in the international publishing field of specialized journals.

Discussion Confinia Cephalalgica was born at the Neurological Institute C. Mondino in Pavia, at the end of the 1980s. At the beginning, it was the official journal of the Italian Society for the Study of Headaches, and then it became the official journal of the University Centres for Adaptive Disorders and Headache. The journal is published 3 times a year and contains original articles, clinical cases of interest, impossible cases, reviews, editorials, therapeutic and historical notes, book reviews and congress reports. The goal of the journal is to constitute a forum for integrating different ideas and expertise through an open dialogue among experts from different disciplines in order to contribute to the advancement and development of knowledge in the field of headaches. The editorial board has always supported the role of the journal as a tool for communication and cultural exchange on headache themes, among Italian-English communities in the world and between Italy and others countries with neolatin language and culture. Not less important is its role as the expression of the patient associations (ALCE Group – CIRNA Foundation) that financially supported the journal. During the last ten years (1997–2006), the journal published upon invitation or by direct submission more than 120 papers, furnished by 354 authors. The journal publishes integrated scientific information, promoting a multidisciplinary environment that involves first of all neurologists, but also philosophers and psychiatrists, physiologists and men of literature. After the restyling of the journal cover in 2004, beginning this year, Confinia Cephalalgica is editing, except for special events, only in an online version (free download at the website www.cefilea.it).

Conclusions Although the paper version will be missed, the new electronic online version is looked at as a challenge, with the desire to be of valuable assistance for physicians and researchers. Thus, the future challenge will be the confrontation and exchange of headache information on the Web.

**HEADACHES: THERAPEUTIC ASPECTS**

**TOPIRAMATE IN MIGRAINE PROPHYLAXIS: AN OPEN STUDY**

R. Iannacchero, F. Peltrone, U. Cannistrà, E. De Caro
Regional Headache Centre, “Pugliese-Ciaccio” Hospital, Catanzaro, Italy; e-mail: rosarioiann@tiscali.it

Introduction Patients who suffer frequent severe migraine or chronic daily headaches are often prescribed prophylactic drugs. A number of beta-blockers, calcium-channel blockers, serotonin agonists, and anti-depressants have been tested as prophylactic agents. Topiramate is a new antiepileptic agent that has GABA agonist properties and has few side effects when used in low doses.

Objective and methods The aim of this study was to examine the effects of topiramate on the frequency and intensity of migraine attacks during prolonged use. Patients who demonstrated 3 to 10 migraine attacks per month; in addition to migraine, also had chronic daily headaches from a variety of causes, and all patients had failed treatment with a number of prophylactic agents.

Results We present 35 patients, who kept a daily diary that recorded the frequency, severity of headaches, and the amount and type of rescue medication used. Over a 3–9 months follow-up, 11 patients (30%) had a very significant improvement in headache frequency (headaches decreased by over 60%), and 11 patients had a moderate improvement in headaches (decrease of 40%–60%). Three patients discontinued therapy due to side effects (lightheadedness, tinnitus, and numbness in hands) and eight patients did not report any improvement despite having been on therapy for over 12 weeks. The remainder of patients had only 8 weeks of therapy.

Conclusions Our open uncontrolled study in patients with resistant headaches suggests that topiramate may be a useful prophylactic medication with limited side effects. A large placebo-controlled study is needed, however, before the results are generalized.

**PROPHYLAXIS OF HEMICRANIA CONTINUA WITH TOPIRAMATE: REPORT OF 2 CASES**

1. A. Palermo, 1G. Giglia, 1A. Sandullo, 1G. Cosentino, 2F. Brighina, B. Fierro
1Department of Neurology, Ophthalmology, Otorhinolaryngology and Psychiatry, University of Palermo, Palermo, Italy; 2General Medicine Clinic, Sciacca, Agrigento, Italy; e-mail: fbrighina@unipa.it

Introduction Hemicrania Continua (HC) is an uncommon and under-recognized primary headache disorder. It is characterized by a strictly unilateral continuous headache of moderate intensity with possible exacerbations, and it is associated with ipsilateral autonomic features, such as ptosis, miosis, conjunctival injection, lacrimation or rhinorhoea, that tend to be less pronounced than those seen with cluster headache [1]. The pathophysiology of HC is poorly understood. HC has generally a prompt and enduring response to indomethacin 25–300 mg daily, although 25%–50% of treated patients develop gastrointestinal side effects and unresponsive forms have been described. Patients who cannot tolerate indomethacin pose a difficult management challenge as no other drug is consistently effective in HC. Recently, Matharu et al. [2] reported 2 patients affected by atypical forms of HC that showed good response to topiramate.

Case reports Here we describe two patients who fulfill both the IHS diagnostic criteria for HC. The physical and neurological examinations and brain magnetic resonance imaging with gadolinium were normal in both patients.

The patients demonstrated a very good response to indomethacin but both developed the most common side effect, gastritis, that led us to stop this treatment. Thus, these patients were started on topiramate with slow titration to 100 mg b.d, and they had a complete benefit with the prophylactic treatment with topiramate after 30 days. The dose of topiramate required to give complete relief of pain was somewhat less than that usually needed for the antiepileptic effect of the drug. There were no side effects during the treatment with topiramate.

Discussion and conclusions Topiramate has multiple mechanisms of action, which include: blockade of the voltage-mediated sodium channels, enhancement of GABA-mediated chloride influx to GABA antagonist of the glutamate kainate/AMPA receptor and carbonic anhydrase inhibition. The mechanisms(s) of action responsible for the beneficial effect in various headache syndromes is currently unknown. Whatever the mechanism, if the favourable response observed in our patients can be confirmed in other cases, it would broaden the therapeutic armamentarium available for the treatment of this severe and sometimes incapacitating condition.

**EFFICACY AND TOLERABILITY OF LEVETIRACETAM IN EPISODIC AND CHRONIC MIGRAINE**

1G. Dalla Volta, 1S. Griffini, 1P. Zavarise, 1A. Pizzini
1Neurology Unit, Clinical Institute, Brescia, Italy; 2Stroke Unit, Vascular Neurology; Civilian Hospital, Brescia, Italy; e-mail: dalla@numerica.it

Background Because of its effect in stabilizing neuronal hyperexcitability, the antiepileptic drug levetiracetam is a promising molecule for the prophylaxis of migraine.
Methods Twenty-five patients with episodic migraine without aura (at least 4 attacks per month of moderate-severe intensity; Group 1) and 18 patients with chronic migraine (no drug abuse; Group 2) were treated with levetiracetam 500 mg/day for 5 days, increased to 1000 mg/day in two administrations, after 5 days. Number of days with headache/month, accompanying symptoms (mild-moderate vs severe), use of symptomatic drugs for migraine attacks (number of drugs), and side effects of levetiracetam were recorded at baseline and at the end of the 3-month treatment period in both groups.

Results One patient in Group 1 did not complete the study because of intolerable side effects (somnolence and asthenia). Patients in Group 1 reported a mean reduction in the number of days/month with headache from 8.4 at baseline to 4.1. In Group 2, 12 patients were nolonger classified as chronic (from 23.8 to 10.3 days/month, mean values), four patients had an improvement of their chronic headache (from 23.8 to 16.2 days/month, mean values) and two had no improvement at the end of the treatment period. Severe accompanying symptoms became mild-moderate in 83% of patients in Group 1 and in 62% of patients in Group 2. Drug intake for acute attacks per month changed from 12.3 at baseline to 5.2 drugs in Group 1 and from 32 to 13 drugs in Group 2. Side effects were somnolence (6 patients - 5 patients), asthenia (4 and 3), postural instability (2 and 0) in Groups 1 and 2, respectively.

Conclusions This study confirms the role of levetiracetam as a potential preventive treatment for migraine.

COMBINED NEUROMUSCULAR RELAXING AND SHIATSU TREATMENT INTEGRATED WITH MELATONIN IN TENSION-TYPE HEADACHE

A. Lera, M. Bernardini
Headache Centre DSM Giulianova, ASL Teramo, Teramo, Italy; e-mail: antonio.lera@asltoraso.it

Objective The aim of this study was to evaluate a combined neuromuscular relaxing and Shiatsu programme integrated with melatonin in the treatment of tension-type headache. We tried to consider a possible positive role of physical activity in reducing the frequency and intensity of headache attacks and, in particular, in decreasing activity limitations at a working, social and family level, and therefore, to evaluate the overall improvement in the patients’ quality of life.

Patients and methods Before enrolment in the study, 20 middle-aged female subjects underwent psychodiagnostic evaluation with the following scales: MIDAS, MSQOL, MQoLQ, HIT, and MSQ. We utilised the MIDAS scale in this study because it is an objective measure of the severity of a headache attack; it specifies the level of inability and is suitable for identifying the appropriate therapy on the basis of the severity level of each patient. MIDAS scores for our patients were between 6 and 10, which indicated no need for pharmacological therapy, excluding headaches with mild (level 1) and severe inability (levels 3–4). The study group, consisting of 10 females aged 35–60 years, underwent combined neuromuscular, relaxing and shiatsu treatment every week, integrated with melatonin retard formulation, 1 tablet per day, for the entire length of the study. For the combined treatment there was a successive prolongation phase: at first, every 15 days for an additional three months, then every month for a further three months. A control group of the same number of subjects did not carry out any treatment programme. At the end of nine months, both the study and control groups underwent another psychodiagnostic evaluation.

Results Comparison of the MIDAS scores between the first and last evaluations showed a decrease of six points in 10% of cases, five points in 20%, four points in 15%, two points in 25%, with no change in 30% of cases in the study group. No statistical difference was observed in the comparison of the same group of MIDAS scores in the control group, indicating a positive result only for the combined neuromuscular relaxing and Shiatsu programme integrated with melatonin.

Conclusions On the basis of our results, we can assert that in the study group, which underwent combined neuromuscular relaxing and Shiatsu treatment integrated with Melatonin retard formulation, the quality of life as evaluated by the MIDAS scale was improved significantly. This combination programme seems to have a positive role in reducing the frequency of headache attacks and in alleviating their severity.

EFFECTS OF DENTAL MALOCCLUSION CORRECTION ON PAIN FROM CHRONIC TENSION-TYPE HEADACHE

L. Di Ianni, E. Tafuri, A. Fabrizio, A. Savini, G. Sidonio, G. Affaitati, R. Lerza, P. De Bignonta, A. Messetti, M.A. Giambertano
Headache Centre, “G. D’Annunzio” University of Chieti, Chieti, Italy; e-mail: lidianni@interfree.it

Introduction Dental malocclusion is a very frequent finding in patients with chronic tension-type headache. The aim of this study was to investigate how malocclusion contributes to both the subjective (number and intensity of attacks) and objective (pain thresholds in muscles of the cervical and upper shoulder regions) painful psychosomatic pathology of this type of headache.

Methods Twenty-five patients (18 women and 7 men, aged 18–36 years) were studied. They had been suffering from chronic tension-type headache for at least 1 year prior to examination (diagnosis performed according to IHS criteria) and also presented dental malocclusion. Their headache pain was located in the occipital, parietotemporal and, in 11 cases, also fronto-orbital regions, bilaterally. In all of them pain thresholds to electrical stimulation were measured bilaterally in the trapezius, sternocleidomastoid and splenius muscles before and 30 days after application of the bite to correct dental malocclusion. Measurements were performed in the pain-free interval. Number and maximal intensity (VAS scale) of headache attacks were also recorded in the month of treatment and compared with those relative to the 30 days preceding treatment.

Results Before treatment, pain thresholds in all muscles were significantly lower when compared to thresholds recorded in corresponding sites of 20 non-headache sufferers (p<0.001) (hyperalgesia). In the month of application of the bite there was a significant reduction in the number of headache attacks (p<0.003) but not of their peak intensity; pain thresholds on day 30 were still lower than normal (p<0.05) but significantly increased with respect to pre-treatment values (p<0.008 for trapezius, p<0.004 for sternocleidomastoid, p<0.007 for splenius). A significant linear correlation was found between the decrease in headache pain and the increase in threshold (p<0.01).

Conclusions In patients with chronic tension-type headache, dental malocclusion contributes directly to the triggering of the painful attacks, probably through sensitization of muscles of the cervical/upper shoulder regions.

EFFICACY OF A WORKPLACE COGNITIVE AND PHYSICAL PROGRAMME ON PSYCHOSOMATIC SYMPTOMS IN A WORKING COMMUNITY WITH HEADACHE, NECK AND SHOULDER PAIN: A LONGTIDUDINAL CONTROLLED STUDY

1. F. Mongini, 1. E. Rota, 2. G. Ciccone, 2. C. Galassi, 2. L. Ferrero, 2. A. Ugolini Headache-Facial Pain Section, Department of Clinical Pathophysiology, University of Turin, Turin, Italy; 2. Unit of Cancer Epidemiology, San Giovanni Battista Hospital, Turin, Italy; e-mail: franco.mongini@unito.it

Objective Our purpose was to examine the effect of a workplace cognitive and physical programme on psychosomatic symptoms in a working community. Materials and methods Three hundred and eighty-four employees of the city of Turin, whose working activities involved public contact (registry and tax office), were divided into two groups: study group (n=192) and controls (n=192). In all subjects data regarding headache, neck and shoulder pain, if present, were collected in a standardized fashion. Each subject underwent a physical examination and muscle palpation of pericranial and cervical muscles. The presence of 28 symptoms, mainly psychosomatic in nature, (such as colitis, gastritis, swallowing difficul-
ties, digestive difficulties, phobias, sleep disorders, palpitations, dizziness, cramps, etc.) were also assessed. These items that belong to those generally investigated when taking a medical history showed in previous studies a significantly higher prevalence in pain patients in respect to a normal population. An instruction programme was then administered to the study group: it consisted of brief shoulder and neck exercises, a relaxation exercise and instructions on how to reduce hyperfunction of the craniofacial and cervical muscles during the day. After six months, all subjects were re-examined in the same way as at baseline and the presence of psychosomatic symptoms was assessed again. In the two groups, the difference between the data at baseline and those at the end was calculated and the data compared (Student's test).

Results In the study group, the mean amount of psychosomatic symptoms decreased significantly (p<0.002) from baseline (7.27±5.19 SD) to the end (5.73±4.77 SD). In the control group no significant difference was observed (baseline: 6.65±5.07 SD; end: 6.55±4.93 SD; p=0.78).

Discussion The data demonstrate that the administration of a simple cognitive instruction programme can significantly decrease psychosomatic symptoms in a working community. This finding, in contrast, may be the direct consequence of the cognitive programme, or may be partially due to the beneficial effects of such programme on the headache, neck and shoulder pain in the study population.

Conclusions A cognitive instruction programme can significantly reduce the presence of psychosomatic symptoms in extensive population samples.

EFFECTIVENESS OF AN INTEGRATED APPROACH IN THE PROPHYLACTIC TREATMENT OF CHRONIC TENSION-TYPE HEADACHE

1,2,3 B. Ciccone, 1,2,3 G. Griso, 1,2,3 S. Lenzuolo
1 Headache Clinic, Medicine of the Future, Acerra, Naples, Italy;
2 Medical Diagnostics Clinic, Mercogliano, Avellino, Italy;
3 Athena Clinic, Saviano, Naples, Italy;
e-mail: b.cicone@libero.it

Introduction Retrospective study of patients from our clinics, suffering from chronic tension-type headache (CTTH), diagnosed in accordance with the criteria of the ICHD-II classification, code 2.3 (OMS G4.2).

Objective The purpose of this study was to demonstrate the effectiveness of an integrated pharmacological and non pharmacological approach compared with an approach that was exclusively pharmacological.

Materials and Methods We selected 14 patients suffering from CTTH, 14 F, mean age 33 years (range 15–59) ±14.1 years, who used an integrated prophylactic therapy, compared with 14 patients suffering from CTTC, 1 M and 13 F, mean age 33 years (range 13–50) ±11.7 years, treated solely with medication. The study was carried out over a period lasting from 60 to 180 days. The patients using the integrated approach received daily medication in addition to a weekly session of relational systemic psychotherapy consisting of individual and familial meetings (7 patients) or osteopathic treatment consisting of craniosacral therapy and visceral manipulation (7 patients). The patients in the control group underwent only daily pharmacological prophylactic treatment.

The clinical diary regarding the headache of each patient was reviewed to determine the number of crises per month and to monitor the percentage decrease of the crises.

Results The patient group following the pharmacological prophylaxis had only an average decrease of 64% in the number of headaches per month.

The patient group using the integrated approach with weekly psychotherapy had an average decrease of 88%, while the patients who underwent craniosacral/visceral manipulation treatment had an average decrease of 92%. Comparison of the two treatments indicated a statistically significant decrease (p<0.005).

Discussion and conclusions The integrated approach in patients with CTTH is more effective than the pharmacological approach alone, as it affects treatment motivation, therapeutic reliability, compliance and the consequent improvement of quality of life.

RATIONAL EMOTIVE BEHAVIOUR THERAPY (REBT) IN TENSION HEADACHE

1 A. Mascaro, 1 I. Salvaggio, 1 E. Adducci, 1 S. Barbì, 1 L. Zappia, 1,2 G. Di Trapani
1 Department of Anaesthesiology and Intensive Care and 2 Department of Neurology, Catholic University Medical School, Rome, Italy; e-mail: iclar@rm.unicatt.it

Introduction During the last few years, many studies have demonstrated how an emotional condition can influence pain. This aspect is especially evident for headache, in which the connection between emotionality, pain, intensity and frequency is very important. In the Centre for Pathophysiology and Pain Therapy of the Catholic University Medical School of Rome, we studied a Rational Emotive Behaviour Therapy (REBT) that underscores the importance of patients’ cognitive processes in the genesis and feeding of emotive and behavioural disturbances.

Materials and Methods From September 2004 to April 2006, after informed consent, we studied 60 patients (35 females and 25 males, mean age 35 years). Their tension headaches (ICHD-II criteria, 2004) were bilateral with occipital localization, without aura, vomiting, photophobia and phonophobia; they had eight crises per month and visual analogue scale (VAS) score=7.

Their clinical history, objective and neurological examinations excluded a secondary headache. We had an indepth conversation with each patient, and we noticed that everyone was depressed or anxious or hostile; we gave them some forms to fill out and a headache diary to complete before and after the start of therapy. They were divided into two randomised groups of 30 patients. The first group was treated with cognitive, emotional and behavioural techniques; the second group was treated with pharmacological therapy with amitriptyline 30 mg/day, alprazolam 0.25 mg/day and celecoxib 200 mg, if needed. They were treated for 6 months.

Results In the first group, treated with cognitive psychotherapy, VAS decreased from 7 to 3, the crises decreased from 8 to 2, and the emotional condition improved with a reduction of depression, anxiety and hostility. In the second group, treated with pharmacological therapy, VAS decreased from 7 to 2, and the crises decreased from 8 to 3.

Conclusions From our results we observed that patients treated with cognitive psychotherapy showed improvement in VAS scores and their emotional condition, and reduction in the number of monthly crises, while patients treated with pharmacological therapy also had improved VAS scores and reduction in the number of crises, but with no modifications of their emotional condition.

GYMNASTIC-PHYSICAL ACTIVITY: PERFECT SHAPE FUNCTION IN MIGRAINE AND CLUSTER HEADACHE

1 A. Lera, 1 M. Bernardini, 1 C. Germani
1 Headache Centre DSM Giulianova, ASL Teramo, Teramo, Italy; 2 Institute of Experimental Research for Motor Sciences Life Quality Project, S. Benedetto del Tronto, Ascoli Piceno, Italy; e-mail: antonio.lera@aslteramo.it

Objective The aim of this study was to evaluate the effects of a programme of gymnastic-physical activity (Perfect Shape System) on the quality of life in a group of subjects suffering from migraine and cluster headache. We tried to consider a possible positive role of physical activity in reducing the frequency and intensity of headache attacks and, in particular, in decreasing inability at a working, social and family level, and therefore, improving overall the patients’ quality of life.

Patients and methods Before enrolment in the study, forty subjects suffering from primary headaches (30 with migraine and 10 with cluster headache) underwent clinical evaluation with the following scales: MIDAS, MSQOL, MSQOL-Q, HIT, and MSQ. We utilised the MIDAS scale in this study since it is an instrument which objectively measures the severity of a headache attack; it specifies the inability level and is suitable for identifying the appropriate therapy on the basis of the
The use of complementary and alternative medicine (CAM) in cluster headache (CH) is a phenomenon about which little is known. This study was undertaken to evaluate the rates, pattern, satisfaction and presence of predictors of CAM use in a clinical population of patients with CH. One hundred CH patients attending three headache clinics were asked to undergo a physician-administered structured interview designed to gather information on CAM use. Past use of CAM therapies was reported by 29% of the patients surveyed, with 10% having used CAM in the previous year. Only 8% of the therapies used were perceived as effective, while a partial effectiveness was reported in 28% of CAM treatments. The most common source of recommendation of CAM was a friend or relative (54%). Approximately 62% of CAM users had not informed their medical doctors of their CAM use. The most common reason for deciding to try a CAM therapy was that it offered a "potential improvement of headache" (44.8%). Univariate analysis showed that CAM users had a higher lifetime number of conventional medical treatments, and, in particular, the Perfect Shape programme, seems to contribute in a positive way to reducing the frequency of headache attacks and to alleviating their severity. However, there were no relevant changes in terms of quality of life parameters between the different forms of primary headaches.

**USE OF COMPLEMENTARY AND ALTERNATIVE MEDICINE BY PATIENTS WITH CLUSTER HEADACHE: RESULTS OF A MULTI-CENTRE HEADACHE CLINIC SURVEY**

1,2P. Rossi, 1P. Tovelli, 1C. Di Lorenzo, 2G. Sances, 1G.C. Manzoni, 2C. Tassorelli, 2G. Nappi

The use of complementary and alternative medicine (CAM) in cluster headache (CH) is a phenomenon about which little is known. This study was undertaken to evaluate the rates, pattern, satisfaction and presence of predictors of CAM use in a clinical population of patients with CH. One hundred CH patients attending three headache clinics were asked to undergo a physician-administered structured interview designed to gather information on CAM use. Past use of CAM therapies was reported by 29% of the patients surveyed, with 10% having used CAM in the previous year. Only 8% of the therapies used were perceived as effective, while a partial effectiveness was reported in 28% of CAM treatments. The most common source of recommendation of CAM was a friend or relative (54%). Approximately 62% of CAM users had not informed their medical doctors of their CAM use. The most common reason for deciding to try a CAM therapy was that it offered a “potential improvement of headache” (44.8%). Univariate analysis showed that CAM users had a higher income, had a higher lifetime number of conventional medical doctor visits, had consulted more headache specialists, had a higher number of CH attacks per year with disease and had a significantly higher proportion of chronic CH vs episodic CH. A binary logistic regression analysis was performed and two variables remained as significant predictors of CAM use, the income level (OR=3.08, 95% CI=1.64–6.7, p<0.0001) and the number of attacks per year with disease (OR=3.08, 95% CI=1.64–6.7, p<0.0001). Our findings suggest that CH patients, in their need of and quest for care, seek and explore both conventional and CAM approaches, even if only a very small minority finds them satisfactory. Conventional MDs and CAM practitioners should be made aware of this redefinition of the role of modern biomedicine, given that they are in a unique position to provide patients with help and guidance.

**STANDARDIZED APPROACH TO PATIENTS WITH MIGRAINE IN A HEART-BRAIN CENTRE: 6-MONTH EXPERIENCE**

1G. Dalla Volta, 1B. Troianiello, 1S. Griffini, 1P. Zavarise, 1A. Pezzini, 1A.M. Lanzone, 1R. Albino, 1M. Guindani
2Neurology Unit, Clinical Institute, Brescia, Italy; 2Stroke Unit, Vascular Neurology, Civilian Hospital, Brescia, Italy; 2St. Rocco Cardiology Clinic, Brescia, Italy; 2Clinical Institute S. Anna, Brescia, Italy; e-mail: dalla@numericait.com

Background Because a pathogenic relationship between patent foramen ovale (PFO) and migraine with aura is assumed, percutaneous closure of PFO has been recently proposed as an effective treatment. However, definitive criteria to identify a priori migraine patients who will benefit from PFO closure and those whose migraine will not be influenced by this treatment are lacking. We propose the standardized approach to these patients in use at the Heart-Brain Centre of the Clinica St Rocco of One, Brescia.

Methods During a 6-month period, 120 patients with migraine with aura, 48 patients with migraine without aura, and 18 patients with cluster headache were evaluated. All subjects underwent a contrast-enhanced transcranial Doppler (TCD) investigation to detect the presence/absence of PFO. This was diagnosed in 62.5% of cases with aura, 37.5% of those without aura, and 38.8% of cluster headache. In the case of a positive finding, a standardized work-up including brain MRI, thrombophilic tests (proteins C and S, antithrombin III, APCR, antithrombin antibodies, total plasma homocysteine, vitamin B12 and folate levels, G1691A polymorphism of factor V, G20210A polymorphism of factor II, C677T polymorphism of MTHFR), ultrasound evaluation of the deep veins of the legs and the carotid-vertebral arteries was carried out. Transesophageal echocardiography was performed in cases of PFO-positivity with curtain effect, MRI evidence of ischemic lesions (MRI+), or evidence of a prothrombotic state (T+). This allowed the identification of co-existent atrial septal aneurysm (ASA).

Discussion and conclusions Based on these findings, PFO closure can be considered in cases with co-existent ASA when at least one of the following conditions is present: curtain pattern on TCD, MRI+, or T+. It can also be considered in those cases without co-existent ASA in which MRI+ or T+ are present. Although the management of PFO in patients with migraine is still a matter of debate, the proposed standardized approach can be of help in selecting patients who will benefit from percutaneous closure in clinical practice.

**EPIDURAL BLOOD PATCH IN THE TRENDLEBURG POSITION TO TREAT HEADACHE BY SPONTANEOUS CSF LEAK**

1E. Ferrante, 1L. Arpino, 1A. Citro, 1R. Wetzl, 1A. Savino, 1R. Sterzi
2Neurosciences and 3Emergency Departments, Niguarda Cà Granda Hospital, Milan, Italy; e-mail: enricoferrante@libero.it

Background Spontaneous intracranial hypotension (SIH) generally results from spontaneous spinal CSF leakage [1]. Treatment is usually conservative but epidural blood patch (EBP) has emerged as the most important nonsurgical treatment for SCFSL [2].

Objective To evaluate the efficacy of epidural blood patch (EBP) in the Trendelenburg position in the treatment of headache by spontaneous CSF leakage (SCSF).

Materials and methods We observed 30 patients with SCFSL between 1992 and 2005. Eleven patients (6 women and 5 men; age range 31–66 years, mean age 40) received EBP. All patches were performed in the lumbar region, using 15 to 30 mL (mean 23 mL) of autologous CSF.
All patients had orthostatic headaches. Other manifestations were nausea, vomiting, mild neck stiffness, tinnitus, blurred vision, diplopia and bilateral upper limb numbness. CT myelography, spinal MRI or brain MRI or radionuclide cisternography showed CSF leak sites in 6 out of 11 patients; 2 sites were at the cervical level, the others at the lumbar level. In 10 out of 11 patients, brain MRI showed diffuse pachymeningeal gadolinium enhancement (neuroimaging of intracranial hypotension). All patients failed an initial conservative treatment, which consisted of bed rest and hydration, over a period of 1 to 13 months. All treated patients became asymptomatic, 1 responded only after 3 EBP, and 1 had a residual mild headache during the Valsalva manoeuvre for 2 months. Until now, none has had a relapse.

Discussion and conclusions Our data confirm the efficacy of EBP in the SCFSFL headache and suggest also the importance of a prolonged Trendelenburg position especially when the leak site is at the cervical level and the autologous blood patch in the lumbar region is performed.

**HEADACHE IN CHILDHOOD AND ADOLESCENCE**

**CLIMATIC VARIATIONS AND MIGRAINE IN CHILDHOOD**

D. Moscato, M.I. Peracchi
Headache Centre, Saint Charles Hospital, Rome, Italy; e-mail: dmoscat@tin.it

The incidence of migraine in childhood has increased in recent years. Up to now that increase has been attributed to the worsening of children’s conditions: the job of both parents, the long distance to school, the high number of separations, divorces etc. [1, 2].

Regardless, the environmental situation, unexpected climatic variations, and elevated levels of pollutants, may also have had a specific influence on migraine.

We tried to estimate the influence of these factors in a group of 120 children (72 F. 48 M, age range 5–17 years) affected by migraine without aura (n=112) and migraine with aura (n=8), assessed from 1995 to 2005. For these patients the headache triggers were evaluated (Table 1).

No significant variations were found in the percentage of stress as a trigger factor, whereas the number and percentages of patients referring atmospheric variations and solar exposure as a triggering factor increased over time.

**Table 1 Trigger Factors**

| 1995 | 1997 | 1999 | 2001 | 2003 | 2005 | Total |
|------|------|------|------|------|------|-------|
| Emotional stress, % | 90 | 90 | 80 | 90 | 100 | 70 | 83 |
| Physical stress, % | 50 | 30 | 30 | 40 | 60 | 30 | 40 |
| Environment stress, % | 70 | 80 | 90 | 50 | 90 | 60 | 73 |
| Lights, % | 30 | 50 | 40 | 60 | 30 | 40 | 48 |
| Smell, % | 40 | 20 | 40 | 60 | 30 | 40 | 33 |
| Smoke, % | 20 | 40 | 20 | 40 | 10 | 20 | 25 |
| Food, % | 20 | 20 | 20 | 10 | 00 | 10 | 15 |
| Climatic Variations, % | 40 | 50 | 60 | 60 | 70 | 80 | 60 |
| Solar exposure, % | 10 | 20 | 40 | 60 | 90 | 70 | 48 |

These preliminary data need to be confirmed by further studies. Among triggers examined, solar exposure as a controllable trigger should be avoided or limited to reduce its influence in inducing migraine attacks.

**TENSION-TYPE HEADACHE IN CHILDREN**

A. Forabosco, T. Grandi, M. Malavasi
University of Modena and Reggio Emilia, School of Dentistry, Modena, Italy; e-mail: forabosco.andrea@unimo.it

Introduction Tension-type headache is a common problem among children in primary school. Dental malocclusion can often be the cause of this form of primary headache [1].

Materials and methods Twenty schoolchildren who had already received a diagnosis of primary headache treated with analgesic substances came to our clinic. An orthodontic evaluation and orthopanoramic X-ray film were performed. All patients were found suffering from malocclusion. Limitation of the functional mandible’s movements, teeth abrasions, and hypertrophy of the mandibular elevator muscles were present. To treat muscular problems originating from the stomatognathic system, an occlusal splint was performed. Intensity [using a graphic rating scale (GRS)] and frequency (daily, weekly, monthly) of headache before treatment (T0), after one month (T1), after three months (T2) and after six months (T3) were recorded. Wilcoxon test was applied for statistical evaluation.

Results All patients showed a considerable reduction of their symptoms. A significant improvement of the intensity and the frequency of headache attacks was registered after treatment (p<0.0001).

Discussion and conclusions The high occurrence of malocclusion in the subjects with tension-type headache seems to play an important role in the genesis of headache. At present, the treatment for patients who suffer from these disorders has increasingly required the need for a collaborative team approach. An orthodontic treatment should be suggested, both for an improvement of the headache and the functional aspects, but the results may not be significant before 2 years [2]. An application of a plate bite, without any drug therapy, can be the treatment of choice to reduce the symptomatology in children suffering from tension-type headaches.

**HEADACHE AND QUALITY OF LIFE IN A CHILD AND ADOLESCENT COHORT**

D. Brovia, S. Cesl, M.M. Cainazzo, L.A. Pini
1School of Specialization in Medical Toxicology, 2School of Specialization in Childhood Neuropsychiatry, University of Modena and Reggio Emilia, Modena, Italy; Toxicology and Clinical Pharmacology, University Hospital of Modena, Modena, Italy; e-mail: pinila@unimore.it

Introduction Up to 10% of children between the ages of 5 and 15 have migraines [1], while an even higher number of adolescents have migraines [2].

The primary aim of this study was to evaluate the quality of life in young patients, using the PED-MIDAS, the QLH-Y Questionnaire and...
Children’s Depression Inventory (CDI) scales. A secondary end-point was to examine changes in clinical picture and diagnoses related to headache treatment.

Methods and patients The study included 70 patients (32 F, 38M; age range: 5–15 years, mean age 12.34±1.91 years) visited in the Moderna Headache Centre between January 2002 and June 2004. At the initial visit, each patient underwent complete history-taking and general and neurological examinations in the presence of a parent. A second follow-up visit was performed in the period January-June 2005; headaches were diagnosed according to the International Headache Society criteria (ICHD-II).

Questionnaire At the follow-up visit, the patients were asked to check MIDAS, QLH-Y and CDI Questionnaires in the presence of a trained doctor. They were urged to express their own judgements, but they could ask a parent for advice.

Results All 70 patients completed the study. Mean illness duration was 44.31 months. Forty-two patients had migraine without aura, 10 had migraine with aura, 18 had tension-type headache (16 with episodic tension-type headache (ETTH) and 2 with chronic tension-type headache (CTTH)). Sixty-eight out of 70 patients confirmed the first diagnosis. The frequency of headache was related to the degree of disability, while the intensity was moderate-severe in almost all patients in spite of disability scores.

Pathological values found in Children’s Depression Inventory (CDI) at the follow-up visit showed that almost 50% of patients had a bad perception of themselves with devaluation and often with feelings of desolation, and thus referred disobedience, asthenia and a negative body image. According to the QLH-Y data, our patients seemed to experience stress, fatigue and somatic symptoms. The most used drug for headache attack was acetaminophen.

Discussion The results of this study suggest that the prevalence of migraine without aura and ETTH decreases with increasing age. Optimal care for children and adolescents with headache can be realized with collaboration among primary care practitioners and headache specialists; behavioural treatment is a foundation for provision of such care.

HEADACHE AND EPILEPSY IN CHILDREN

E. Tozzi, R. Savini, I. Florio, A. Di Fonzo, B. Giobbi Paediatric Clinic, University of L’Aquila, L’Aquila, Italy; e-mail: etozzi@univaq.it

Introduction The association between headaches and epileptic seizures is a well-known phenomenon. The headache could be pericentral and interictal, in 50% of epileptic patients [1]. The incidence of interictal headache is not clear, while the intensity is moderate-severe in almost all patients in spite of disability scores.

Materials and methods Forty-three children aged 4–18 years, 22 males and 21 females, affected by epilepsy and suffering from headache, were studied in order to verify the correlation between pericentral and interictal headache. Headache was diagnosed according to ICHD-II criteria, and epilepsy according to ILAE 1989 criteria.

Results In 20 children, the headache started before epilepsy began and in 5 children after epilepsy began. In 26 children, the diseases were contemporary. There was no correlation between the region of EEG anomalies and the side of pain. Only 3 children, suffering from BVSWE, and 5, suffering from generalized epilepsy, showed headache in the vertex region.

In 11 children (25%), there was a temporal relationship between headache and epilepsy. In 4 patients with seizures while sleeping, the headache occurred upon awakening, in 3 children with occipital epilepsy the headache was postictal, and in 4 children with photosensitive epilepsy the headache was precordial and was triggered by photic stimuli (TV, play station). The preictal headache was defined by children as stabbing, the postictal headache as migraine-like.

Conclusions Migrainous-like headache is prevalent among epileptic children during the peri-ictal and interictal periods. In fact, migraine-like headache was found in 50% of patients with photosensitive epilepsy and migraine in 100% of children with rolandic epilepsy.

PREVALENCE OF MIGRAINE IN FAMILIES OF CHILDREN WITH PANAYIOTOPOULOS SYNDROME

P. Mariotti, P. De Rose, F. Perrino, D. Martinelli, R. Chiera, S. Staccioli, A. Sacco, G. Vasco, D. Lettori, D. Battaglia Unit of Child Neuropsychiatry, Polyclinic “A. Gemelli”, Catholic University, Rome, Italy; e-mail: pmariotti@rm.unicatt.it

Introduction Early-onset benign occipital seizure susceptibility syndrome or the “Panayiotopoulos type” of childhood epilepsy with occipital paroxysms (PS) is a partial form of epilepsy that occurs in 13% of children aged 3–6 years with one or more non-febrile seizures [1]. Although many authors have studied the relationship between headache and PS, there do not seem to be any clear results [1].

Aim The aim of our study was to determine the relationship between migraine and PS in childhood and the prevalence of family history of migraine and epilepsy in patients with PS.

Patients and methods This was a retrospective study conducted at the Child and Adolescent Neuropsychiatry Unit of our University Hospital, in patients recruited between 1999 and 2006, diagnosed as PS on the basis of the ILAE Task Force on Classification and Terminology criteria. Anamnestic, clinical, and instrumental data were collected to clarify the semiology and the frequency of the seizures. All patients underwent a video-EEG during wake and sleep cycles with HP and ILS, and a brain MRI. All patients were given the specific record for headache in children and adolescent patients of the Italian Child and Adolescent Neuropsychiatry Society Group. The diagnosis of migraine was based on the criteria of The International Classification of Headache Disorders, 2nd edition (ICHD-II).

Migraine prevalence in children with PS and in their families was compared with a member of the general population of the same age group.

Results We evaluated 20 patients with PS, 11 males and 9 females, mean age at the end of follow-up=8.5 years, range 4 to 14 years. Among these, 7/20 (35%) had migraine (six migraine without aura and one with visual aura). Regarding family history: 13/20 cases (65%) were positive for migraine, 5/20 (25%) for epilepsy, 4/20 (20%) for both, and 4/20 for febrile seizures. All children with migraine also had a family history of migraine. The headache usually started in the same year in 2/7 cases (29%) or after the diagnosis of epilepsy in 5/7 (71%).

Conclusions So far, no study has shown a clear relationship between a family history of migraine and PS. In particular, Panayiotopoulos says “there is no family history of similar disorders of benign childhood seizure susceptibility, epilepsies or migraine” in children with PS [2].
To our knowledge, this is the first retrospective study to report a prevalence of 65% for migraine, 25% for epilepsy, and 20% for both in family members of affected children. PS and migraine are probably genetically determined. Our study supports the hypothesis of a clinical continuum between migraine and epilepsy, particularly PS that share similar characteristics and a familial spectrum.

HEADACHE AND CARDIO-EMBOLIC STROKE: THE IMPORTANCE OF CLINICAL SUSPICION. REPORT OF A PEDIATRIC CASE

G. Indolfi, S. Trapani, C. Massai, L. Calistri, C. Scalas, M. Resti
Department of Paediatrics, University of Florence, Anna Meyer Paediatric Hospital, Florence, Italy; Children’s Headache Centre, Paediatric Neurology Clinic, Anna Meyer Paediatric Hospital, Florence, Italy; e-mail: g.indolfi@meyer.it

A 14-year-old boy, with an underlying history of asymptomatic ostium secundum atrial septal defect and a family history negative for vascular diseases or coagulation disorders, was admitted to the emergency department of a general hospital because of a severe headache and visual disturbance that began during a school examination. As brain CT scan and fundoscopic examination were normal, he was dismissed with the diagnosis of migraine with aura and asymptomatic therapy. Twelve hours later for the persistence of the same complaints, he was newly admitted: physical examination showed right homonymous hemianopsia and a systolic ejection murmur, but no other abnormalities. EEG showed bioelectric abnormalities on the left temporal and occipital regions and magnetic resonance imaging revealed acute left occipital infarction and normal head and neck vessels. He was then transferred to our tertiary care paediatric hospital; in the following days his clinical conditions were stable. An expanded investigation for an underlying prothrombotic tendency showed increased plasma homocysteine (29 micromol/L) and homozgyosity for the methylenetetrahydrofolate reductase gene C677T polymorphism. Anticoagulant therapy, folic acid and vitamin B12 supplementation was given and the 6-month follow-up was uneventful: right temporal hemianopsia persisted. Atrial septal defect was subsequently closed via percutaneous approach.

Arterial ischemic stroke is being increasingly diagnosed and recognized in childhood. Recognition of clinical stroke may be difficult, particularly in infants and young children. Ischemic events are usually suspected when a child presents with abrupt onset of a hemiparesis but the initial symptom can be a common complaint, such as isolated headache and/or subtle and difficult to recognize focal sensory deficits or visual disturbances. A detailed history focused on the most frequent risk factors, such as congenital thrombophilic states, cardiac diseases, infections, trauma and sickle cell anemia, represents the initial screening for the diagnosis of paediatric stroke since multiple risk factors coexist in individual patients [1]. As demonstrated by our case report, magnetic resonance is the imaging modality of choice to confirm that an acute ischemic event has occurred and to determine the extent and location of acute cerebral injury, the patency of major neck and intracranial arteries and relative cerebral perfusion.

It is crucial to increase clinician awareness of stroke also in children as clinical suspicion can reduce the time lag to diagnosis and to appropriate treatment of this disease [2].

HEADACHE IN ADOLESCENTS: SYMBOLIC MEANING BETWEEN CLINICAL DATA AND INNER PSYCHIC LIFE

D. Ragusa, D. Puma, V. Raeli
Division of Child Neurology and Psychiatry. “G.F. Ingrassia” Hospital, AUSL 6, Palermo, Italy; e-mail: donatellaragusa@inwind.it

Introduction Primary headaches can present occasional and nonspecific anatomical and/or functional anomalies, but although they do not have an aetiological and pathophysiological role in producing painful attacks, they can influence the symptomatic course through the symbolic meaning that they have for the patients and their family. We present and analyse three cases of adolescents with these characteristics.

Case 1: A twelve-year-old boy with a story of migraine-type attacks occurring every weekend for the last three months; brain MRI showed a pineal cyst and for this reason he underwent neurosurgical consultation and another MRI with gadolinium; during the clinical evaluation, migraine appeared the day before every examination and afterwards, he was migraine-free for long periods.

Case 2: An eleven-year-old boy suffering from tension-type headache and depressive symptoms: his father was operated on for cerebral aneurysm, the boy’s EEG showed positive occipital sharp waves, evoked by all IPS frequencies; undergoing MRI, which was normal, and clinical interviews regarding the family’s fears, in the last two years, the boy no longer suffered from headache.

Case 3: A fourteen-year-old girl presented with very frequent and severe migraine-type attacks for about two months; she had been wearing an orthodontic appliance for over two years. The decision to remove the orthodontic appliance resulted in the disappearance of the headache.

Discussion The nonspecific anomalies, considered as symbols, found in these three clinical cases are “dumb elements” [1], but they represent an important meaning in the patients’ inner psychic life and may induce the manifestation of some developmental emotional problems. In the first case, pineal cyst may represent a need of dependence in the relationship between the patient and his busy family, and may induce the manifestation of some developmental emotional problems. In the second case, the abnormal EEG and the father’s history of cerebral aneurysm produced in the boy an identity problem with a father who was always absent. The clinical and psychological therapy and normal brain MRI examination disintegrated the “symbol” with the disappearance of the headache. The removal of the orthodontic appliance allowed the patient to become independent without being forced to accept a self-image that the mother imposed.

Conclusions The three cases, with their different data and life events, confirm that nonspecific signs need attention, because their symbolic meaning may be significant and influence the course of pain.

PRESENT AND PAST PSYCHOPATHOLOGY IN CHILDHOOD MIGRAINE: A STUDY WITH THE CHILD BEHAVIOUR CHECKLIST

F. Salvadori, V. Gelmi, F. Muratori
Division of Child Neuropsychiatry, Scientific Institute Stella Maris, Department of Neurosciences, University of Pisa, Pisa, Italy; e-mail: francesco.salvadori@inpe.unipi.it
A strong association has been observed between migraine and psychiatric problems such as depression and anxiety. In the 7–16 year group, children of the MG had significantly higher mean CBCL scores — i.e., nearer to the clinical threshold — than those of the CG in several scales: total problems (p<0.01), internalizing (p<0.001), somatic (p<0.001), anxious/depressive (p<0.01), thoughts (p<0.05) and attention problems (p<0.01). At 4–6 years, significantly higher scores between the MG and the CG were found in the total problems scale (p<0.001), internalizing (p<0.001), somatic (p<0.001), anxious/depressive (p<0.01), attention (p<0.01), social problems (p<0.01) and withdrawn (p<0.05). At 0–3 years, significantly higher scores between the MG and the CG were found in the total problems scale (p<0.01), internalizing (p<0.05), somatic (p<0.001), and anxious/depressive (p<0.01). In a longitudinal perspective we did not demonstrate statistically significant differences between 7–16 and 4–6 year age periods. Comparing the age periods of 4–6 years and 0–3 years, significant differences were found in total problems (p<0.01), internalizing (p<0.001), somatic (p<0.01) and also in externalizing (p<0.01) and aggressive syndrome scale (p<0.01), but not in the anxious/depressive scale.

Discussion

Our study suggests the association between migraine, depression and anxiety during childhood and adolescence. The internalizing component (depression and anxiety) may represent a persistent factor that feeds the migraine. The demonstration of an internalizing score in a headache patient, by means of the CBCL, could be of the utmost importance to prevent migraine from becoming chronic.

Conclusions

Migraine may begin during childhood/adolescence with a symptomatology, which may have its roots in previous behavioural problems. Even if they rarely reach the clinical threshold with the CBCL questionnaire, children who develop migraine are different from healthy children for the higher rate of behavioural problems. Migraine could be considered the expression of a previous vulnerability.

HEADACHE IN CHILDHOOD AND ADOLESCENCE

DEPRESSION AND CHRONIC HEADACHE IN CHILDHOOD AND ADOLESCENCE

M.A. Iavoni, O. Papa, E. Cesaroni, C. Cardinali

Riunite University Hospitals, Pediatric Neurology Department, Children’s Hospital “G. Salesi”, Ancona, Italy; e-mail: npisalesi@ao-salesi.marche.it

Introduction

The role and importance of the psychiatric and psychological aspects in determining and influencing the resurgence and evolution of chronic headache in childhood and adolescence have been the object of numerous studies. Many authors have tried to analyse the possible correlations between depression, anxiety disorders and headache.

Objective

The aim of our study was to analyse the possible correlations between chronic headache and depressive disorder with or without anxiety disorder.

Materials and methods

Sixty-two children (38 males, 24 female; mean age 9 years, 5 months; range: 6–13 years) were enrolled from 493 subjects seen from 2003 to 2005 among the outpatients from the Departments of Headache and Psychology of the “Ospedali Riuniti “G. Salesi” Children’s Hospital. Fifty-two patients affected with chronic headache were subdivided into 3 subgroups: chronic tension-type headache (CTTH), chronic daily headache (CDH) and mixed headache (CTTH and headache); 10 patients affected from episodic tension-type headache (ETTH) were identified according to IHCD-II 2004 criteria. The patients under investigation were evaluated by the juvenile headache flow-chart (haematological, clinicians, neurophysiologic and neuroimaging exams) and by a psychodiagnostic protocol that we use in our centre.

Results

Following the DSM IV criteria the subjects of the two groups were subdivided in:
Chronic headache is frequently associated with depressive disorders. Twenty-five children (mean age 11 years, n = 26) were recruited. In 23 children, migraine without aura was diagnosed according to the International Headache Society criteria (IHS-II, 2004), while the remaining 2 children had migraine with aura. Results Before treatment, our patients showed 8±5.7 (mean±standard deviation) pain attacks per month. The children received a mean topiramate dose of 1.3 mg/kg/day, ranging from 0.5 to 1.8 mg/kg/day, for a period of 3.2±1.2 months. Treatment was effective (reduction in attack number ≥ 50%) in 19 out of 25 children (76%). In particular, 3 patients (12%) became free from migraine episodes. One patient (4%) interrupted the treatment for adverse side effects (excessive drowsiness). Seven patients in which the initial treatment was effective underwent a worsening in migraine frequency after topiramate interruption and needed a further treatment after 4.3±2.8 months. Six patients had a reduction in the frequency of pain episodes greater than 75%, while in one child the therapy was ineffective. Two patients had a third treatment at 3 and 4 months, respectively, after interrupting the second topiramate cycle. The therapy was ineffective in both patients. Adverse events were observed in 6 out of 25 children (24%). They consisted of drowsiness (3 patients), anxiety (1 patient), weight loss (2 patients), and behavioural disturbances (3 patients).

Discussion and conclusions Our results suggest that topiramate is a useful and safe tool in paediatric migraine prophylaxis. Even low doses allowed us to control migraine in most of our paediatric patients, thus improving their quality of life.

MELATONIN, 3 MG, IS EFFECTIVE FOR MIGRAINE PREVENTION ALSO IN SCHOOL-AGED PATIENTS

M. Carotenuto, F. Tagliente, F. Ruja, A. Pascotto
Department of Developmental Neurology and Psychiatry, Second University of Naples, Naples, Italy; e-mail: marco.carotenuto@unina2.it

Background Hypothalamic dysfunction may be present in migraine and in circadian periodicity of headache attacks, more specifically, the amplitude of certain circadian rhythms. In the past years, melatonin has been considered a useful tool for migraine prevention. The aim of our study was to investigate the efficacy and safety of topiramate in the prevention of paediatric migraine.

Materials and methods Twenty-five children (mean age 11 years, range 5–16 years; 10 females, 15 males) were recruited. In 23 children, migraine without aura was diagnosed according to the International Headache Society classification (IHS-II, 2004), while the remaining 2 children had migraine with aura.

Results Before treatment, our patients showed 8±5.7 (mean±standard deviation) pain attacks per month. The children received a mean topiramate dose of 1.3 mg/kg/day, ranging from 0.5 to 1.8 mg/kg/day, for a period of 3.2±1.2 months. Treatment was effective (reduction in attack number ≥ 50%) in 19 out of 25 children (76%). In particular, 3 patients (12%) became free from migraine episodes. One patient (4%) interrupted the treatment for adverse side effects (excessive drowsiness). Seven patients in which the initial treatment was effective underwent a worsening in migraine frequency after topiramate interruption and needed a further treatment after 4.3±2.8 months. Six patients had a reduction in the frequency of pain episodes greater than 75%, while in one child the therapy was ineffective. Two patients had a third treatment at 3 and 4 months, respectively, after interrupting the second topiramate cycle. The therapy was ineffective in both patients. Adverse events were observed in 6 out of 25 children (24%). They consisted of drowsiness (3 patients), anxiety (1 patient), weight loss (2 patients), and behavioural disturbances (3 patients).

Discussion and conclusions Our results suggest that topiramate is a useful and safe tool in paediatric migraine prophylaxis. Even low doses allowed us to control migraine in most of our paediatric patients, thus improving their quality of life.

Efficacy of Topiramate in Paediatric Migraine Prophylaxis

E. Conicella, F. Vigevano, M. Valeriani
DEA and HD Headache Centre, Division of Neurology, “Bambino Gesù” Paediatric Hospital, IRCCS, Rome, Italy; e-mail: m.valeriani@tiscali.it

Introduction Migraine is the most common type of primary headache in childhood and often hampers common daily routines.

Objective The aim of our study was to investigate the efficacy and safety of topiramate in the prevention of paediatric migraine.

Materials and methods Twenty-five children (mean age 11 years, range 5–16 years; 10 females, 15 males) were recruited. In 23 children, migraine without aura was diagnosed according to the International Headache Society classification (IHS-II, 2004), while the remaining 2 children had migraine with aura.

Results Before treatment, our patients showed 8±5.7 (mean±standard deviation) pain attacks per month. The children received a mean topiramate dose of 1.3 mg/kg/day, ranging from 0.5 to 1.8 mg/kg/day, for a period of 3.2±1.2 months. Treatment was effective (reduction in attack number ≥ 50%) in 19 out of 25 children (76%). In particular, 3 patients (12%) became free from migraine episodes. One patient (4%) interrupted the treatment for adverse side effects (excessive drowsiness). Seven patients in which the initial treatment was effective underwent a worsening in migraine frequency after topiramate interruption and needed a further treatment after 4.3±2.8 months. Six patients had a reduction in the frequency of pain episodes greater than 75%, while in one child the therapy was ineffective. Two patients had a third treatment at 3 and 4 months, respectively, after interrupting the second topiramate cycle. The therapy was ineffective in both patients. Adverse events were observed in 6 out of 25 children (24%). They consisted of drowsiness (3 patients), anxiety (1 patient), weight loss (2 patients), and behavioural disturbances (3 patients).

Discussion and conclusions Our results suggest that topiramate is a useful and safe tool in paediatric migraine prophylaxis. Even low doses allowed us to control migraine in most of our paediatric patients, thus improving their quality of life.
suprachiasmatic nucleus and melatonin have been suggested to play a role in the pathogenesis [1]. Altered melatonin levels have been found in cluster headache, migraine with and without aura, menstrual migraine, and chronic migraine. Melatonin may have many metabolic effects, such as anti-inflammatory effects (melatonin and indomethacin share similar chemical structure), reducing the up-regulation of proinflammatory cytokines, and inhibiting nitric oxide synthase activity and dopamine release. Melatonin administration is thus a possible candidate for migraine prevention [2].

Objective The aim of this open trial was to test the hypothesis of the potential effectiveness of melatonin for migraine prophylaxis also in school-aged children.

Patients and methods We performed an open-label trial of melatonin, 3 mg, for migraine prevention. Twenty-three patients (11 M, 12 F) aged 6–15 years (mean 12.8 years, SD±1.38) with episodic migraine with or without aura according to ICHD-II 2004 criteria, were screened for the baseline period. All patients started prophylactic treatment with melatonin, 3 mg, 10 minutes before bedtime for 3 months. A complete clinical interview and examination as well neuropsychological recordings (wake and sleep EEG) were performed for each patient. Study participants experienced between two and six attacks per month. Exclusion criteria included the presence of sleep disorders, as confirmed by the mothers of all subjects who filled out the Sleep Disturbances Scale for Children (SDSC). The SDSC is a sleep questionnaire that consists of 26 items subdivided into 6 sleep disorder subscales according to American Sleep Disorders Association criteria: DIMS (disorders in initiating and maintaining sleep), SDB (sleep disordered breathing), DA (disorders of arousal), SWTD (sleep-wake transition disorders), DES (disorders of excessive somnolence), SHY (sleep hyperhydrosis).

Results Twenty out of 23 patients completed the study (86.9%). That patients (85%, 17/20) who completed the study had at least a 50% reduction in intensity and frequency of headache attacks. Nobody reported an increase in headache frequency. Complete (100%) response was achieved in 12 patients (60%) and no adverse effects were recorded.

Conclusions There is increasing evidence to indicate that the hypothalamus plays a major role in the pathophysiology of several of the primary headache disorders, such as migraine, and hypnic headache [1, 2]. Melatonin, an indole compound derived from serotonin, was reported safe and effective in adult patients [2], but no data were available for school-aged children. This is an original study to assess melatonin, 3 mg, for prophylactic treatment of headache also in childhood.

EMERGENCY IN CHILDREN, BRAIN TUMOUR: CLINICAL CASES
D. Moscato, M.I. Peracchi
Headache Centre, Saint Charles Hospital, IDI Rome, Rome, Italy; e-mail: dnosc@tin.it

Brain tumours in children, due to their characteristic of slow invasive-ness and easy infiltration in the nervous tissue, tend to give specific symptoms only when they are of a large size. We present a few cases which came to our attention last year. Martina is an eight-year-old girl, who came to us due to widespread headache that started three years before. She was a child presenting a conflicting separation since the age of 3, which she responded to initially with hyporexia; she was anxious, agitated, very attached to her mother. The symptoms seemed linked more to the psychological aspects. Neurological testing was negative. During Day Hospital she presented an intense headache crisis, which receded without treatment with NSAIDs. A MRI identified a new formation in the posterior cranial fossa. Surgical intervention revealed an adenoma, 2 months later, the headache had fully disappeared.

Giorgia is 13-years old, suffering from migraine for two years. Her parents are separated, and she is very attached to her mother, who still sleeps with her. In the past 3 months, she has suffered from sleep disturbances, sleep talking and frequent accentuated awakenings, with intense headache almost daily during the same period. Vomiting with coughing was present, but the girl had been following a diet for one month. The neurological examination was negative. Emotional tension was evident in the family. During hospitalisation she experienced slight difficulty in climbing the stairs. TAC shows a 6 cm hypodense formation in the temporal occipital area. Surgical resection of a grade 1 medulloblastoma was followed by one cycle of chemotherapy.

Gianluca is 5-years old, and had been complaining of intense cluster headache for a few months after occipital cranial trauma without loss of consciousness. The headache worsened overtime with an increase in severity. During Day Hospital, 10 days after the trauma, he complained of diffuse violent headache, with crying. Neurological examination was negative except for slight fluctuations on Romberg. CT showed a voluminous new formation in the posterior cranial fossa. He was transferred to the Neurosurgery Unit, where neurological signs began with vomiting, drowsiness, dysmetria, and dysarthria. Surgical resection of a Grade 4 medulloblastoma was followed by chemotherapy and radiotherapy. The following year he relapsed, and was operated on again, followed by another cycle of chemotherapy, but his condition worsened. Sixteen months after being diagnosed, he died.

Conclusions In the cases presented above the specific symptoms of intracranial pressure, vomiting and papilledema stasis without headache, as well as those linked to focality, are absent. Also, the neurological examination yielded no precise indications. The same psychological characteristics could have led to the wrong diagnosis. Observation overtime of the reactions of children to headache during Day Hospital had led us to select neuroimaging testing, which led to the diagnosis. Therefore, we believe that a child with an important headache must always be visited during a crisis.

HEADACHE IN A PAEDIATRIC EMERGENCY DEPARTMENT
1L. Calistri, 2M. Guasti, 2C. Scalas, 3M. de Luca, 4F. Festini, 5S. Masi, 6F. Mannelli
1Headache Centre for Childhood and Adolescence, Paediatric Neurological Clinic, 2Emergency Department, 3Department of Paediatrics, University Hospital “A. Meyer”, Florence, Italy; e-mail: lcalistri@meyer.it

Objective The aim of this study was to determine the prevalence of headache as the chief complaint in patients presenting to a paediatric Emergency Department (ED), to assess its characteristics, to study the spectrum of primary and secondary headache diagnoses and to analyze the diagnostic tests and the treatment applied.

Methods We retrospectively analysed the clinical records of patients presenting to the ED of the Paediatric Hospital A. Meyer of Florence, Italy with the chief complaint of headache from January 1, 2005, to June 30, 2005. All the patients underwent a clinical evaluation/case history, and if necessary also had laboratory or imaging tests performed. The ED records were searched for triage color code, age, gender, location of pain, associated symptoms, case history, physical examination (particularly neurological examination), assessments and specialists’ visits, therapy at the ED, time spent at the ED, and outcome (discharge – hospitalization – further assessments at the Centre for Headache in Childhood and Adolescence).

Nosology was established using the International Classification for Headache Disorders ICDH-II.
Hemorrhagic prolactinomas are rare in children [2]. Patients usually present headache and visual field deficits.

Discussion and conclusions

She has never suffered from headache. Prior to the resection, she needed substitutive hormonal therapy and, since then, has had no headache. Pituitary apoplexy has been documented a rare benign pathology.

The first case presented a painful ophthalmoplegic migraine (ICHD-II, 2004 classification, point 13.17), a very rare condition in young patients, or as Tolosa–Hunt syndrome diagnosed as ophthalmic migraine (ICHD-II, 2004 classification, point 13.16), which also presents with similar features, although with unilateral pain. Neuroimaging, however, documented a rare benign pathology.

In the second case, the patient may be affected by migraine without aura, considering the family history, the type and stability of attacks over time, the resolution with vomiting after the attacks, and the later evolution of the clinical features. The cases reported are characterized by peculiar clinical features. The first one presented a pituitary apoplexy, rare in pediatric age group, and a monolateral visual loss with VEPs abnormalities consistent with an optic neuritis. In the second one, instead, the oligomenorrhea although of a mild pattern was the key-sign for the correct diagnosis of a secondary headache.

SPHENOID MUCOCELE IN CHILDREN: DESCRIPTION OF TWO CASES

P.A. Battistella, L. Bianchin, S. Sartori, A.M. Laverda, R. Faggin, I. Toldo, P. Drigo

Department of Paediatrics, University of Padua, Padua, Italy; e-mail: battist@pediatria.unipd.it

Introduction

Sphenoid mucoceles are very rare, benign cystic lesions (1% of all localizations) [1, 2]. Due to connection with several structures (cavernous sinuses, pituitary, orbits and choanae), clinical manifestations can be extremely variable.

Subjects and methods

Case 1: An 8-year-old male presented with a subcontinuous mild-moderate, bifrontal, pressing headache on awakening for seven days, without any associated symptoms. On the eighth day, an acute left III cranial nerve palsy with exotropia, ptosis and mydriasis appeared. CT scan showed an erosion of the parassellar structures and MRI revealed a lesion of the sphenoid body, hyperintense on both T1-T2 sequences without enhancement. The maxillofacial CT scan confirmed the sphenoid body lesion. Hormone levels, visual fields and acuity were normal. After ten days the headache spontaneously disappeared, but nerve deficit persisted. Endoscopic trans-sphenoidal permitted total removal of the lesion, followed by histological confirmation and complete resolution of the third cranial nerve palsy. He was asymptomatic at the 5-year follow-up.

Case 2: A 12-year-old male since last year suffered from recurrent, pulsating, weekly headache, localized to the right fronto-ocular region, with photophobia and phonophobia, sometimes nausea, rarely vomiting and responsive to NSAIDs. His father suffered from migraine without aura. During the recent admission to our hospital the neurological examination was negative. Brain MRI showed hypointense signal on T1 and hyperintense signal on T2 in the left part of the sphenoid sinus, with partial involvement of the ipsilateral ethmoid and maxillary sinuses. Sinus CT confirmed a left-sphenoidal mucocele, with indication for an endoscopic sphenoidotomy.

Discussion and conclusions

The first case presented a painful ophthalmoplegia which, considering only the clinical picture, could be diagnosed as ophthalmoplegic migraine (ICHD-II, 2004 classification, point 13.17), a very rare condition in young patients, or as Tolosa–Hunt syndrome (ICHD-II, 2004, point 13.16), which also presents with similar features, although with unilateral pain. Neuroimaging, however, documented a rare benign pathology.

In the second case, the patient may be affected by migraine without aura, considering the family history, the type and stability of attacks over time, the resolution with vomiting after the attacks, and the later evolution of the clinical features. The cases reported are characterized by peculiar clinical features. The first one presented a pituitary apoplexy, rare in pediatric age group, and a monolateral visual loss with VEPs abnormalities consistent with an optic neuritis. In the second one, instead, the oligomenorrhea although of a mild pattern was the key-sign for the correct diagnosis of a secondary headache.

TWO CLINICAL CASES OF RED EAR SYNDROME (RES) CONNECTED WITH HEADACHE

C. Termine, C. Pintacrona, G.A. Magro, A. Vecchio
Multispecialty Paediatric University Department, Maternity Unit, AUSL 6, Child Neuropsychiatry Division, Palermo, Italy; e-mail: chiaratermine@virgilio.it

Introduction The Red Ear Syndrome (RES) is characterized by sudden events when the patient feels a kind of uneasiness (sometimes a real painful sensation) mainly localized in one ear, which becomes red and warm. Sometimes it happens in a spontaneous way, sometimes it is caused by triggers, like touching the ears, feeling warm or cold, moving the neck, chewing, drinking, coughing or sneezing. The first description of RES dates back to 1996 thanks to Lance [1] who studied its characteristics in 12 patients, some of them having a past of headache. More recently, Raieli et al. 2002) [2] discovered a closer connection between RES and migraine in eight patients. Here, we present two clinical cases that might confirm what is reported in the recent literature. The first one concerns a little boy of 11 years affected by an almost daily headache bilaterally localized to the forehead, causing heaviness of variable intensity lasting about 30 minutes together with nausea, vertigo, phosphenes, pallor, perspiration and hyporexia. The second case concerns a little boy of 7 years who was observed because of a symptomatology of weekly headaches, localized on the parietotemporal side, characterized by pulsating, variable intensity, and lasting no more than 30 minutes. In both cases, the headaches were accompanied by the reddening of a single ear.

Materials and methods Before admittance a careful clinical history was taken according to our protocol for headache diagnosis, and through an accurate clinical and instrumental neurological examination, following the guidelines of the Italian Headache Society for the Study of Headache (SISC).

Results This diagnostic approach allowed us to place the patients’ symptomatology in a context of headache connected with RES, bypassing the difficulty in classifying the kind of headache they were affected by, as often happens in patients of that age.

Conclusions Our experience is further proof of the observation made by other authors regarding the connection between RES and headache symptomatology. This suggests the possibility that RES, when present in patients suffering from headache, is epidemiologically understated at present, and the debate is still open on the possibility of including RES in an unclassified category of headache disorders according to the IHS classification.
