LINEAR CONNECTIONS FOR REPRODUCING KERNELS ON VECTOR BUNDLES

DANIEL BELTÎTĂ AND JOSÉ E. GALÉ

18 July 2013

Abstract. We construct a canonical correspondence from a wide class of reproducing kernels on infinite-dimensional Hermitian vector bundles to linear connections on these bundles. The linear connection in question is obtained through a pull-back operation involving the tautological universal bundle and the classifying morphism of the input kernel. The aforementioned correspondence turns out to be a canonical functor between categories of kernels and linear connections. A number of examples of linear connections including the ones associated to classical kernels, homogeneous reproducing kernels and kernels occurring in the dilation theory for completely positive maps are given, together with their covariant derivatives.

1. Introduction

The theory of reproducing kernels and of their applications to the study of Lie group representations has undergone an impressive development over the years; see for instance the excellent monograph [Ne00] and the references therein. The questions addressed in the present paper belong to the apparently not yet explored differential geometric aspects of this theory. More specifically we show that, under mild assumptions, the smooth reproducing kernels on an infinite-dimensional Hermitian vector bundle give rise to linear connections on that bundle, and this

The second-named author has also been supported by Project E-64, D.G. Aragón, Spain.
correspondence sets up a functor between suitably defined categories of reproducing kernels and linear connections, respectively. This functor also turns out to be canonical in some sense (Theorem 4.3). In the case of the tautological vector bundle over the Grassmann manifold associated to a complex Hilbert space, the universal connection corresponds to the so-called universal reproducing kernel that we pointed out in the earlier paper [BG11]. We also discuss a number of specific examples including the classical Hardy and Bergman kernels and others on infinite-dimensional manifolds.

The circle of ideas approached here is motivated by the interest in understanding certain physical models ([Od88], [Od92]) as well as the geometric realizations for certain representations of groups of invertible elements in $C^*$-algebras; see for instance [BR07], [BG08], [BG09] or [Ne13]. Such realizations, of Borel-Weil type, were constructed by using suitable reproducing kernels on homogeneous vector bundles and a rich panel of differential geometric features of operator algebras turned out on this occasion. The ideas were developed in a categorial framework in [BG11], where the geometric features of reproducing kernels have been reinforced in relation with the geometry of tautological vector bundles taken as universal objects. We were thus naturally led to investigating the differential geometric features of reproducing kernels. The geometric significance of such kernels had been also pointed out for instance in [BH98] and more recently, in the very fine paper [Hi08].

Section 2 is devoted to the reductive structures in the framework of Banach-Lie groups. We briefly discuss here the linear connections induced by the reductive structures and we then present some examples related to the $C^*$-algebras and which are important for producing geometric realizations for representations of certain Banach-Lie groups. The reproducing kernels on Banach vector bundles that we deal with in this paper are discussed in Section 3. Our main constructions of linear connections out of reproducing kernels are presented in Section 4. We compute their covariant derivative in terms of the input reproducing kernel (Theorem 4.2), and we also study their functorial properties (Theorem 4.3). And finally, a panel of significant examples of reproducing kernels is discussed in Section 5. Namely, we look at the usual type of operator-valued reproducing kernels, including the classical reproducing kernels of Hardy or Bergmann type, the homogeneous reproducing kernels that we earlier used in the geometric representation theory of Banach-Lie groups, or the kernels that are implicit in the dilation theory of completely positive maps on $C^*$-algebras. In Appendix A we provide some auxiliary properties of connections on Banach bundles and we emphasize the operation of pull-back, which plays a key role throughout this paper.

Let us mention that in the present paper we only show how to define the linear connection induced by a reproducing kernel and study the very basic properties of the correspondence between these two types of objects. Topics like the deep significance of such connections for the complex structures or $C^*$-Hermitian structures on infinite-dimensional vector bundles, the analysis of the linear connections associated with reproducing kernels arising in representations of semisimple Lie groups in function spaces, or applications to Cowen-Douglas operators will be treated in forthcoming papers.
2. REDUCTIVE STRUCTURES FOR BANACH-LIE GROUPS

In this section we introduce the abstract notion and example which, as inherent in universal bundles, will enable us in Section 4 to define connections associated with reproducing kernels on general vector bundles.

2.1. Linear connections induced by reductive structures. We first make the definition of the reductive structures we are interested in. Several versions of this notion showed up in the literature of differential geometry in infinite dimensions; see for instance [MR92], [ACS95], [CG99], and the references therein. Nevertheless it seems to us that, maybe due to the fact that the existing literature was largely motivated by problems involving operator algebras, one considered mainly reductive structures on homogeneous spaces of groups of invertible elements in unital associative Banach algebras. See however [Nee02, Def. 4.1] for the related general notion of a normed symmetric Lie algebra. We next introduce the reductive structures on the natural level of generality, which does not require Banach algebras or $C^*$-algebras but rather Banach-Lie groups.

**Definition 2.1.** A reductive structure is a triple $(G_A, G_B; E)$ where $G_A$ is a real Banach-Lie group with Lie algebra $\mathfrak{g}_A$, $G_B$ is a Banach-Lie subgroup of $G_A$ with Lie algebra $\mathfrak{g}_B$, and $E: \mathfrak{g}_A \to \mathfrak{g}_A$ is a continuous linear map with the following properties: $E \circ E = E$; $\text{Ran } E = \mathfrak{g}_B$; and for every $g \in G_B$ the diagram

$$
\begin{array}{ccc}
\mathfrak{g}_A & \xrightarrow{\text{Ad}_{G_A}(g)} & \mathfrak{g}_A \\
E & \downarrow{} & \downarrow{} \\
\mathfrak{g}_A & \xrightarrow{\text{Ad}_{G_A}(g)} & \mathfrak{g}_A
\end{array}
$$

is commutative.

A morphism of reductive structures from $(G_A, G_B; E)$ to $(\tilde{G}_A, \tilde{G}_B; \tilde{E})$ is a homomorphism of Banach-Lie groups $\alpha: G_A \to \tilde{G}_A$ such that $\alpha(G_B) \subseteq \tilde{G}_B$ and the diagram

$$
\begin{array}{ccc}
\mathfrak{g}_A & \xrightarrow{\text{Ad}_{G_A}(g)} & \mathfrak{g}_A \\
E & \downarrow{} & \downarrow{} \\
\mathfrak{g}_A & \xrightarrow{\text{Ad}_{G_A}(g)} & \mathfrak{g}_A
\end{array}
$$

is commutative. For instance, a family of automorphisms of any reductive structure $(G_A, G_B; E)$ is provided by $\alpha_g: x \mapsto gxg^{-1}, G_A \to G_A (g \in G_B)$.

We will see in Theorem 2.2 below that if $\rho$ is a uniformly continuous representation from $G_B$ on a Hilbert space $\mathcal{H}_B$, then any reductive structure for $G_A$ and $G_B$ as above gives rise to a connection on the homogeneous vector bundle $\Pi: D = G_A \ltimes G_B \mathcal{H}_B \to G_A/G_B$ induced by $\rho$. Recall that $G_A \ltimes G_B \mathcal{H}_B$ is the cartesian product $G_A \times G_B$ quotient the equivalence relation

$$(g, h) \sim (g', h')$$

iff there exists $w \in G_B$ such that $g' = gw, h' = \rho(w^{-1})h$, endowed with its canonical structure of Banach manifold; see [KM97]. In order to make the statement, we first note that, on account of Remark A.2, the tangent bundle $\tau_D: TD \to D$ can be described as the mapping

$$
\tau_D: (G_A \ltimes \text{Ad}_{G_A} \mathfrak{g}_A) \times (G_B \ltimes \text{Ad}_{G_B} \mathfrak{g}_B) (\mathcal{H}_B \oplus \mathcal{H}_B) \to G_A \times G_B \mathcal{H}_B
$$
given by $[((g, X), (f, h))] \mapsto [(g, f)]$.

**Theorem 2.2.** Let $(G_A, G_B, E)$ be a reductive structure and $\rho: G_B \to \mathcal{B}(\mathcal{H}_B)$ be a uniformly continuous representation. Then the homogeneous vector bundle $\Pi: D = G_A \times_{G_B} \mathcal{H}_B \to G_A/G_B$ has a linear connection $\Phi_E : TD \to TD$ given by $[((g, X), (f, h))] \mapsto [((g, E(X)), (f, h))] = [((g, 0), (f, d\rho(E(X))f + h))]$.

**Proof.** First we check that the equality in the image of $\Phi$ holds. Take an arbitrary element $(u, Y) \in G_B \ltimes_{\Ad_{G_B}} g_B$. Since

$$d\rho(Y) = \rho(u^{-1})d\rho(\Ad_{G_B}(u)Y)\rho(u),$$

it follows from the matrix expression of $T\rho(u, Y)$ in Remark 2.2 that

$$T\rho(u, Y)^{-1} = \begin{pmatrix} \rho(u^{-1}) & 0 \\ -\rho(u^{-1})d\rho(\Ad_{G_B}(u)Y) & \rho(u^{-1}) \end{pmatrix},$$

for every $u \in G_B$ and $Y \in g_B$. Hence, if $(g, X) \in G_A \ltimes_{\Ad_{G_A}} g_A$ we have

$$(g, E(X)) \cdot (u, Y) = (gu, \Ad_{G_B}(u^{-1})E(X) + Y)$$

and $T\rho(u, Y)^{-1} \cdot (f, h) = (\rho(u^{-1})f, -\rho(u^{-1})d\rho(\Ad_{G_B}(u)Y)f + \rho(u^{-1})h)$.

Then the equality of equivalence classes in the definition of $\Phi_E$ follows just taking $u = 1_B$ and $Y = -E(X)$.

Analogously, it is not difficult to check that the mapping $\Phi_E$ is well defined. In effect, for $(g, X)$ and $(u, Y)$ as above we have

$$[((g, E(\Ad(u^{-1})X) + Y), (T\rho)(u, Y)^{-1}(f, h))$$

$$= ((g u, \Ad(u^{-1})E(X) + Y), (T\rho)(u, Y)^{-1}(f, h))$$

$$= ((g, E(X)) \cdot (u, Y), (T\rho)(u, Y)^{-1}(f, h))$$

$$\sim ((a, E(X)), (f, h)),$$

where we have used in the first equality the commutativity of the diagram in Definition 2.1.

The fact that $\Phi$ is smooth follows since $(g, X, f, h) \mapsto (g, E(X), f, h)$ is a smooth map on $G_A \times g_A \times \mathcal{H}_B \times \mathcal{H}_B$, and the corresponding quotient map

$$(G_A \times g_A) \times (\mathcal{H}_B \times \mathcal{H}_B) \to (G_A \ltimes_{\Ad} g_A) \ltimes_{(G_B \ltimes_{\Ad} g_B)} (\mathcal{H}_B \oplus \mathcal{H}_B) = TD$$

is a submersion (see e.g., [KM97], Th. 37.12).

Finally, the connection properties are readily checked. 

**Definition 2.3.** The connection $\Phi_E$ constructed in Theorem 2.2 will be called the **linear connection induced by the reductive structure** $(G_A, G_B; E)$.

**Remark 2.4.** In the definition of the connection $\Phi_E$, the expression

$$\Phi_E [([(g, X), (f, h))]) = [((g, E(X)), (f, h))]$$

reflects the fact that $\Phi_E$ is a linear connection on the $\Pi: G_A \times_{G_B} \mathcal{H}_B \to G_A/G_B$ induced by the principal connection $E$ on the principal bundle $G_A \to G_A/G_B$. Complementarily, the presentation

$$\Phi_E [([(g, X), (f, h))]) = [((g, 0), (f, d\rho(E(X))f + h))]$$
emphasizes on the fact that the range of the connection $\Phi_E$ lies in the vertical subbundle of $T(G_A \times G_B \mathcal{H}_B)$.

We will now show that the reductive structures and pull-backs of connections are compatible, in the sense that connections induced by reductive structures are invariant under the pull-back action. Specifically, let $\alpha: G_A \rightarrow \tilde{G}_A$ be a morphism of reductive structures from $(G_A, G_B, E)$ to $(\tilde{G}_A, \tilde{G}_B, \tilde{E})$. Let $\bar{\rho}_B: \tilde{G}_B \rightarrow \mathcal{B}(\mathcal{H}_B)$ a uniformly continuous representation and define $\rho_B := \bar{\rho}_B \circ \alpha|_{G_B}$. Thus we can construct the homogeneous vector bundles $\Pi: \tilde{D} = \tilde{G}_A \times_{\tilde{G}_B} \mathcal{H}_B \rightarrow \tilde{G}_A/\tilde{G}_B$ carrying the linear connections $\Phi_E$ and $\tilde{\Phi}_E$, respectively, induced by the corresponding reductive structures (see Definition 2.3).

Set $\Theta = (\delta, \zeta)$ where

\[
\zeta: gG_B \mapsto \alpha(g)\tilde{G}_B, \ G_A/G_B \rightarrow \tilde{G}_A/\tilde{G}_B
\]

and

\[
\delta: [(g, f)] \mapsto [(\alpha(g), f)], \ G_A \times_{G_B} \mathcal{H}_B \rightarrow \tilde{G}_A \times_{\tilde{G}_B} \mathcal{H}_B.
\]

It is readily seen that the pair $\Theta = (\delta, \zeta)$ is a morphism of the bundle $\Pi$ into $\tilde{\Pi}$. Let $\Theta^*(\tilde{\Phi}_E)$ denote the pull-back of the connection $\tilde{\Phi}_E$ through $\Theta$, in accordance with Definition A.7.

**Proposition 2.5.** In the above setting, $\Theta^*(\tilde{\Phi}_E) = \Phi_E$.

**Proof.** The tangent map $T\delta: TD \rightarrow T\tilde{D}$ is given by

\[
T\delta: \left[\left(\left(\left((g, X), (f, h)\right)\right)\right)\right] \mapsto \left[\left(\left((\alpha(g), d\alpha(X)), (f, h)\right)\right)\right], \ TD \rightarrow T\tilde{D}.
\]

Therefore, by Definition 2.2 we get

\[
\left(\left(\left(\left((T\delta) \circ \Phi_E\right)\left(\left(\left(\left((g, X), (f, h)\right)\right)\right)\right)\right)\right)\right) = T\delta \left(\left(\left(\left((g, E(X)), (f, h)\right)\right)\right)\right)
\]

\[
= \left(\left(\left(\left((\alpha(g), d\alpha(E(X)), (f, h))\right)\right)\right)\right)
\]

\[
= \left(\left(\left(\left((\alpha(g), E(d\alpha(X)), (f, h))\right)\right)\right)\right)
\]

\[
= \left(\left(\left(\left(\tilde{\Phi}_E \left(\left(\left((\alpha(g), d\alpha(X)), (f, h))\right)\right)\right)\right)\right)\right)
\]

\[
= \left(\left(\left(\left(\Phi_E \circ T\delta\right) \left(\left(\left((g, X), (f, h))\right)\right)\right)\right)\right),
\]

for every $g \in G_A, X \in \mathfrak{g}_A, f, h \in \mathcal{H}_B$, where the third equality follows since $\alpha$ is a morphism of reductive structures. Thus $\Theta^*(\tilde{\Phi}_E) = \Phi_E$ by Definition A.7. \hfill \Box

In the following remark we sketch a method for computing the covariant derivative for the linear connection induced by a reductive structure in the particular case when the construction of the homogeneous vector bundle involves the restriction of a representation of the larger group. This computation in the finite-dimensional situation can be found in [BR90]. In the special case when $G_A$ is the group of invertible elements of some associative Banach algebra, the Maurer-Cartan form introduced below was also constructed in [MR92] subsect. 3.1.

**Remark 2.6.** Let $(G_A, G_B; E)$ be a reductive structure and denote $m = \text{Ker} E$, so that $\mathfrak{g}_A = \mathfrak{g}_B + m$ and $\text{Ad}_{G_A}(G_B)m = m$.

1. There exists a natural isomorphism of vector bundles $T(G_A/G_B) \simeq G_A \times G_B m$ (see for instance the proof of [BG08 Cor. 5.5]), where the latter homogeneous
bundle is defined by using the adjoint action of $G_B$ on $m$. It follows that the function
\[ \beta : G_A \times_{G_B} m \to g_A, \quad \beta([[g, X]]) = \text{Ad}_{g_A}(g)X \]
can be thought of as a $g_A$-valued differential 1-form $\beta \in \Omega^1(G_A/G_B; g_A)$, to be called the Maurer-Cartan form of the reductive structure under consideration. This vector-valued differential form essentially comes from an embedding of the tangent vector bundle $T(G_A/G_B)$ into the trivial vector bundle $(G_A/G_B) \times g_A$ over $G_A/G_B$. Specifically, we have $T(G_A/G_B) \simeq G_A \times_{G_B} m \to G_A \times_{G_B} g_A$ and also the $G_A$-equivariant trivialization of vector bundles $G_A \times_{G_B} g_A \simeq (G_A/G_B) \times g_A$, $[[g, X]] \mapsto (gG_B, \text{Ad}_{g_A}(g)X)$.

(2) A similar trivialization can be set up for any homogeneous vector bundle whose construction involves the restriction of a representation of the larger group. More precisely, if $\rho : G_A \to \mathcal{B}(E)$ is a uniformly continuous representation on some Banach space $E$, then we have the (inverse to each other) isomorphisms of vector bundles over $G_A/G_B$,
\[ G_A \times_{G_B} E \simeq (G_A/G_B) \times E \]
given by $[[g, v]] \mapsto (gG_B, \rho(g)v)$ and $(gG_B, v) \mapsto [[g, \rho(g)^{-1}v]]$, respectively. Since there exist one-to-one correspondences between the smooth $E$-valued functions or differential forms on $G_A/G_B$ and the sections or differential forms with values in the trivial vector bundle $(G_A/G_B) \times E \to G_A/G_B$, we can use the above isomorphisms of vector bundles in order to define the covariant derivative of $E$-valued functions
\[ \nabla : C^\infty(G_A/G_B; E) \to \Omega^1(G_A/G_B; E) \] (2.1)
as the covariant derivative induced by the reducible structure $(G_A, G_B; E)$ and the representation $\rho$.

(3) For every $F \in C^\infty(G_A/G_B; E)$ we denote by $(d\rho \circ \beta).F \in \Omega^1(G_A/G_B; E)$ the differential form defined for every $z \in G_A/G_B$ and $X \in T_z(G_A/G_B)$ by
\[ ((d\rho \circ \beta).F)(X) = (d\rho(\beta_z(X)))(z), \]
where $\beta_z := \beta|_{T_z(G_A/G_B)} : T_z(G_A/G_B) \to g_A$ and $d\rho : g_A \to \mathcal{B}(E)$ is the derived representation. The method of proof of [BR90, Prop. 1.1], which extends directly to the present infinite-dimensional case (see also [KM97, Th. 37.23(9) and Th. 37.30–31]), leads to the following conclusion. If $\rho : G_A \to \mathcal{B}(E)$ is a representation as above, then the covariant derivative (2.1) can be computed for every $F \in C^\infty(G_A/G_B; E)$ by the formula $\nabla F = dF - (d\rho \circ \beta).F$, that is,
\[ \nabla F([[g, X]]) = (dF([[g, X]])) - \rho(g)d\rho(X)\rho(g)^{-1}F(gG_B) \]
for all $g \in G_A$ and $X \in m$, which follows by also using the expression of $\beta$ given in item (1) above and the fact that $d\rho(\text{Ad}_{g_A}(g)X) = \rho(g)d\rho(X)\rho(g)^{-1}$ for all $g \in G_A$, $X \in g_A$.

2.2. Some reductive structures related to $C^*$-algebras. Next we give some key examples of reductive structures and morphisms between them.

Example 2.7 (Lie group representations). Let $(G_A, G_B; E)$ be a reductive structure and let $\rho_A : G_A \to \mathcal{B}(\mathcal{H}_A)$ be a uniformly continuous unitary representation such that $\rho_A|_{G_B}$ has a non-trivial invariant closed subspace $\mathcal{H}_B \subset \mathcal{H}_A$. Denote $\rho_B(g) := \rho_A(g)|_{\mathcal{H}_B}$ for every $g \in G_B$ and define
- $\tilde{G}_A = U(\mathcal{H}_A)$, the unitary operators on $\mathcal{H}_A$;
Let $G_B = U(H_A) \cap \{p\}'$, the subgroup of $U(H_A)$ formed by the operators commuting with the orthogonal projection $p$ on $H_B$ (that is, the operators that leave $H_B$ invariant);

- $E\colon \tilde{G}_B = u(H_A) \to \tilde{g}_B = u(H_A) \cap \{p\}'$, where $u(H_A) = \{X \in B(H_A) : X^* = -X\}$ and for $X \in B(H_A)$ we take $E(X) := pXp + (1 - p)X(1 - p)$.

Then the mapping $\rho_A \colon G_A \to \tilde{G}_A$ is a morphism of reductive structures from $(G_A, G_B; E)$ to $(\tilde{G}_A, \tilde{G}_B; \tilde{E})$.

**Example 2.8** (conditional expectations on $C^*$-algebras). Let $A$ be a unital $C^*$-algebra with a unital $C^*$-subalgebra $B$ for which there exists a conditional expectation $E : A \to B$. This means that $E$ is a linear projection on $A$ with $\text{Ran} \ E = B$ and norm one. By Tomiyama’s theorem we have moreover that

$$E(b_1 ab_2) = b_1 E(a)b_2 \text{ and } E(b^*) = E(b)^* \quad (a \in A; b_1, b_2 \in B),$$

and additionally $E(1_A) = 1_B (= 1_A)$. Let $G_A$ denote for $A \in \{A, B\}$ the Banach-Lie group of invertibles in $A$ endowed with its norm topology. Then the Lie algebra of $G_A$ is $\mathfrak{g}_A = \mathfrak{A}$, with the element $X$ of $\mathfrak{g}_A$ obtained by derivation of the path $e^{tX}$ at $t = 0$. Since in this $C^*$ case we have that $\text{Ad}(g)a = gag^{-1}$ for every $g \in G_A$ and $a \in A$, the expectation $E$ satisfies the conditions of Definition 2.1 so that $(G_A, G_B; E)$ is a reductive structure.

If for two triples $(A, B; E)$, $(\tilde{A}, \tilde{B}; \tilde{E})$ as above we also have a bounded $*$-homomorphism $\phi : A \to \tilde{A}$ satisfying $\phi \circ E = \tilde{E} \circ \phi$ then $\alpha := \phi|G_A$ defines a morphism between the reductive structures $(G_A, G_B; E)$ and $(G_{\tilde{A}}, G_{\tilde{B}}; \tilde{E})$.

The reductive structures $(U_A, U_B; E|_{u_A})$ and $(U_{\tilde{A}}, U_{\tilde{B}}; \tilde{E}|_{u_{\tilde{A}}})$ defined by the unitary groups have a similar property, where we recall that the unitary group $U_A = \{u \in A \mid uu^* = u^*u = 1\}$ is a Banach-Lie group whose Lie algebra is $\mathfrak{u}_A = \{x \in A \mid x^* = -x\}$, and similarly for the other unitary groups involved here.

**Example 2.9** (completely positive maps). Let $A$ be a unital $C^*$-algebra and $H_0$ be a complex Hilbert space. Recall that a unital linear mapping $\Psi : A \to B(H_0)$ is said to be completely positive if the linear mapping

$$\Psi_n := \Psi \otimes \text{id}_{M_n(\mathbb{C})} : M_n(A) = A \otimes M_n(\mathbb{C}) \to M_n(B(H_0))$$

is positive (i.e., it maps positive elements to positive elements) for all $n \geq 1$. It is well known that every conditional expectation is a completely positive map.

By the Stinespring dilation procedure, for a given completely positive map $\Psi : A \to B(H_0)$, there are a Hilbert space $H$, an isometry $V : H \to H_0$ and a unital $*$-representation of $C^*$-algebras $\lambda : A \to B(H)$, which is induced by the left multiplication in $A$, such that

$$\Psi(a) = V^* \lambda(a) V \quad (a \in A).$$

Then the representation $\lambda$ is called a Stinespring dilation or representation associated with $\Psi$. Details can be found for instance in [Pa02].
Example 2.10 (universal bundles). Let \( \mathcal{H} \) be a complex Hilbert space. The Grassmann manifold of \( \mathcal{H} \) is

\[
\text{Gr}(\mathcal{H}) := \{ \mathcal{S} \mid \mathcal{S} \text{ closed linear subspace of } \mathcal{H} \}.
\]

It is well known that it has the structure of a complex Banach manifold (see also [DG01]). The set \( \mathcal{T}(\mathcal{H}) := \{(\mathcal{S}, x) \in \text{Gr}(\mathcal{H}) \times \mathcal{H} \mid x \in \mathcal{S}\} \subseteq \text{Gr}(\mathcal{H}) \times \mathcal{H} \) is also a complex Banach manifold, and the mapping \( \Pi_{\mathcal{H}} : (\mathcal{S}, x) \mapsto \mathcal{S}, \mathcal{T}(\mathcal{H}) \to \text{Gr}(\mathcal{H}) \) is a holomorphic Hermitian vector bundle on which \( U(\mathcal{H}) \) acts holomorphically (non-transitively on the base \( \text{Gr}(\mathcal{H}) \) if \( \dim \mathcal{H} \geq 2 \); see [Up85] Ex. 3.11 and 6.20. We call \( \Pi_{\mathcal{H}} \) the universal (tautological) vector bundle associated with the Hilbert space \( \mathcal{H} \). A canonical connection can be defined on that bundle, which relies on the preceding examples. To see this, let us consider the connected components of \( \text{Gr}(\mathcal{H}) \).

For every \( \mathcal{S} \in \text{Gr}(\mathcal{H}) \) denote by \( p_{\mathcal{S}} : \mathcal{H} \to \mathcal{S} \) the corresponding orthogonal projection. Take \( \mathcal{S}_0 \in \text{Gr}(\mathcal{H}) \) and put \( p := p_{\mathcal{S}_0} \). The connected component of \( \mathcal{S}_0 \in \text{Gr}(\mathcal{H}) \) is given by

\[
\text{Gr}_{\mathcal{S}_0}(\mathcal{H}) := \{ u_{\mathcal{S}_0} \mid u \in U(\mathcal{H}) \} = \{ \mathcal{S} \in \text{Gr}(\mathcal{H}) \mid \dim \mathcal{S} = \dim \mathcal{S}_0, \dim \mathcal{S}^\perp = \dim \mathcal{S}_0^\perp \}
\]

\[
\simeq U(\mathcal{H})/U(p) \simeq U(\mathcal{H})/(U(\mathcal{S}_0) \times U(\mathcal{S}_0^\perp))
\]

where \( U(p) := \{ u \in U(\mathcal{H}) \mid u_{\mathcal{S}_0} = \mathcal{S}_0 \} \). (See for instance [Up85] Prop. 23.1 or [BG09] Lemma 4.3.)

By restricting \( \Pi_{\mathcal{H}} \) to \( \mathcal{T}_{\mathcal{S}_0}(\mathcal{H}) := \{(\mathcal{S}, x) \in \mathcal{T}(\mathcal{H}) \mid \mathcal{S} \in \text{Gr}_{\mathcal{S}_0}(\mathcal{H})\} \) we obtain the Hermitian bundle \( \Pi_{\mathcal{H},\mathcal{S}_0} : \mathcal{T}_{\mathcal{S}_0}(\mathcal{H}) \to \text{Gr}_{\mathcal{S}_0}(\mathcal{H}) \). The map

\[
U(\mathcal{H}) \times_{U(p)} \mathcal{S}_0 \ni [(u, x)] \mapsto (u_{\mathcal{S}_0}, ux) \in \mathcal{T}_{\mathcal{S}_0}(\mathcal{H})
\]

is a diffeomorphism of vector bundles between \( U(\mathcal{H}) \times_{U(p)} \mathcal{S}_0 \to U/U(p) \), where the representation of \( U(p) \) on \( \mathcal{S}_0 \) is just the tautological action, and \( \Pi_{\mathcal{H},\mathcal{S}_0} : \mathcal{T}_{\mathcal{S}_0}(\mathcal{H}) \to \text{Gr}_{\mathcal{S}_0}(\mathcal{H}) \). See [BG09] Prop. 4.5.

On the other hand, we have a conditional expectation

\[
E_p : B(\mathcal{H}) \to \{ p \}', \quad X \mapsto E_p(X) := pXp + (1 - p)X(1 - p),
\]

where \( \{ p \}' = \{ X \in B(\mathcal{H}) \mid Xp = pX \} \). By restricting \( E_p \) to the Lie algebra \( \mathfrak{u}(\mathcal{H}) := \{ X \in B(\mathcal{H}) \mid X^* = -X \} \) of \( U(\mathcal{H}) \) and applying Theorem 2.2 to the reductive structure \( (U(\mathcal{H}), U(p); E_p |_{\mathfrak{u}(\mathcal{H})}) \), we obtain the following canonical connection on the universal bundle \( \mathcal{T}(\mathcal{H}) \to \text{Gr}(\mathcal{H}) \). Recall that \( \text{Gr}_{\mathcal{S}_0}(\mathcal{H}) \), for \( \mathcal{S} \) running over \( \text{Gr}(\mathcal{H}) \), are the connected components of \( \text{Gr}(\mathcal{H}) \).

**Definition 2.11.** In the framework of Example 2.10 the universal (linear) connection on the tautological bundle \( \Pi_{\mathcal{H},\mathcal{S}_0} : \mathcal{T}_{\mathcal{S}_0}(\mathcal{H}) \to \text{Gr}_{\mathcal{S}_0}(\mathcal{H}) \) is the mapping

\[
\Phi_{\mathcal{S}_0} : T(\mathcal{T}_{\mathcal{S}_0}(\mathcal{H})) \to T(\mathcal{T}_{\mathcal{S}_0}(\mathcal{H}))
\]

given by

\[
[(u, X), (x, y)] \mapsto [[(u, Xp(X)), (x, y)] = [[(u, 0), (x, E_p(X)x + y)]],
\]

for \( u \in U(\mathcal{H}) \), \( X \in \mathfrak{u}(\mathcal{H}) \), and \( x, y \in \mathcal{S}_0 \). Then the universal connection \( \Phi_{\mathcal{H}} \) on the tautological bundle \( \Pi_{\mathcal{H}} : \mathcal{T}(\mathcal{H}) \to \text{Gr}(\mathcal{H}) \) is defined by

\[
\Phi_{\mathcal{H}}((u, X)) := \Phi_{\mathcal{S}_0}((u, X))
\]

for every \( (u, X) \in T(\mathcal{T}(\mathcal{H})) \) with \( (u, X) \in T(\mathcal{T}_{\mathcal{S}_0}(\mathcal{H})) \), \( \mathcal{S}_0 \in \text{Gr}(\mathcal{H}) \).
Remark 2.12. The expression of the connection $\Phi_H$ on the sub-bundle $\Pi_{H,S_0}$ depends obviously on the realization of $\Pi_{H,S_0}$ as a homogeneous vector bundle, given by the diffeomorphism $T_{S_0}(H) = T_S(H) \equiv U(H) \times_{U(p_S)} S$, for $S$ running over the component $\text{Gr}_{S_0}(H)$. However, we can say that $\Phi_{S_0}$ is unique in the sense that it is invariant under the action of $U(H)$:

Let $\alpha \in U(H)$ so that $S_1 := \alpha S_0 \in \text{Gr}_{S_0}(H)$. Then there is the natural diffeomorphism

$$U(H) \times_{U(p_{S_0})} S_0 \to U(H) \times_{U(p_{S_1})} S_1, \quad [(u,x_0)] \mapsto [(\alpha u \alpha^{-1}, \alpha x_0)],$$

which induces the diffeomorphism $T_\alpha : T(T_{S_0}(H)) \equiv T(T_{S_1}(H))$, between the corresponding homogeneous tangent bundles, given by

$$T_\alpha : [(u,X),(x_0,y_0)] \mapsto [(\alpha u \alpha^{-1}, \alpha X \alpha^{-1}, \alpha x_0, \alpha y_0)].$$

Then it is readily seen that, on the level of connections, $\Phi_{S_1} = T_\alpha \circ \Phi_{S_0} \circ (T_\alpha)^{-1}$, which is to say, $\Phi_H$ is $U(H)$-equivariant.

In the sequel, and particularly in what concerns Theorem 4.3 whenever we deal with connections on $T(T(H))$ we will be assuming that an element $S_0$ has been fixed in every connected component $\text{Gr}_{S_0}(H)$ of $\text{Gr}(H)$, and that the connection $\Phi_{S_0}$ is referred to that element as indicated above.

Universal connections on finite-dimensional bundles were studied in several papers including for instance [NR61], [NR63], [Sch80], and [PR86].

It turns out that the Grassmannian objects that we are considering here fit also well in the setting given in the above Example 2.9. In fact, the compression mapping

$$\Psi_{S_0} : X \mapsto p \circ X \circ \iota_{S_0}, \quad B(H) \to B(S_0),$$

where $\iota_{S_0}$ is the inclusion $S_0 \to B(H)$, is a unital completely positive mapping satisfying $\Psi_{S_0} \circ E_p = \Psi_{S_0}$ and the vector bundle defined by $(B(H), \{p^V, E_p; \Psi_{S_0}\})$ as in Example 2.9 coincides with $\Pi_{H,S_0}$.

We now provide a formula for the covariant derivative corresponding to the universal connection on a tautological bundle, which will be needed in the proof of a more general result of this type, given in Theorem 4.2 below. Related finite-dimensional formulas are implicit in [Le68, Ch. III] and [PR86], but we should mention that the approach to the following result is quite different in a couple of respects, beyond the obvious fact that we are working here in infinite dimensions. More specifically, our starting point is a connection defined as a splitting of the tangent space of the tautological vector bundle, rather than the corresponding covariant derivative as in the aforementioned references. Secondly, the following statement and proof emphasize the role of the orthogonal projections on closed subspaces in order to compute the covariant derivative. As the orthogonal projections are just the basic pieces of the universal reproducing kernels (see Example 3.7 below), we thus have an illustration of the main theme of the present paper, namely that the reproducing kernels give rise to linear connections of the bundles where these kernels live. That is nontrivial even in the case of the tautological bundles associated with finite-dimensional Hilbert spaces, and yet we were unable to find any reference for that relationship in the earlier literature.

Proposition 2.13. Let $S_0 \in \text{Gr}(H)$. If $\sigma \in \Omega^0(\text{Gr}_{S_0}(H), T_{S_0}(H))$ is a smooth section, then there exists a unique smooth function $F_\sigma \in C^\infty(\text{Gr}_{S_0}(H), H)$ such that
\( \sigma(\cdot) = (\cdot, F_\sigma(\cdot)) \) and we have

\[
\nabla \sigma(X) = (S, p_S(dF_\sigma(X))), \quad S \in \text{Gr}_{S_0}(H), X \in T_S(\text{Gr}_{S_0}(H)),
\]

where \( p_S \) is the orthogonal projection from \( H \) onto \( S \).

**Proof.** We use the tautological representations

\[
U(S_0) \times U(S_0^\perp) \xrightarrow{\iota^R} B(S_0) \text{ and } U(S_0) \times U(S_0^\perp) \xrightarrow{\iota^L} U(H) \xrightarrow{\iota} B(H)
\]

for constructing the homogeneous vector bundles

\[
\Pi_0: D_0 := U(H) \times U(S_0) \times U(S_0^\perp) \xrightarrow{\iota} U(H)/(U(S_0) \times U(S_0^\perp)) \text{ and } \Pi_1: D_1 := U(H) \times U(S_0) \times U(S_0^\perp) \xrightarrow{\iota} U(H)/(U(S_0) \times U(S_0^\perp)).
\]

Then Remark 2.6(2) provides a \( U(H) \)-equivariant diffeomorphism

\[
\delta_{S_0}: U(H) \times U(S_0) \times U(S_0^\perp) \xrightarrow{\text{iso}} U(H)/(U(S_0) \times U(S_0^\perp)) \times H
\]

which together with the natural diffeomorphism

\[
\zeta_{S_0}: U(H)/(U(S_0) \times U(S_0^\perp)) \rightarrow \text{Gr}_{S_0}(H)
\]

provide an isomorphism between \( \Pi_1 \) and the trivial bundle \( \text{Gr}_{S_0}(H) \times H \rightarrow \text{Gr}_{S_0}(H) \). Also, \( \Pi_0 \) is a \( U(H) \)-homogeneous subbundle of \( \Pi_1 \) and the pair \( (\delta_{S_0}, \zeta_{S_0}) \) restricts to an isomorphism from \( \Pi_0 \) onto the tautological bundle \( \pi_{H,S_0}: T_{S_0}(H) \rightarrow \text{Gr}_{S_0}(H) \).

Now for \( j = 0,1 \) let \( \Phi_j : T(D_j) \rightarrow T(D_j) \) denote the linear connection induced by the reductive structure \( (U(H), U(S_0) \times U(S_0^\perp); E_{\text{PSO}}) \) and \( \nabla_j \) be the corresponding covariant derivative. It easily follows by Theorem 2.2 that \( \Phi_1|_{T(D_0)} = \Phi_0 \), and then Proposition 3.4 shows that \( \nabla_1 \) agrees with \( \nabla_0 \). By taking into account the aforementioned isomorphisms of homogeneous vector bundles, it then follows that the covariant derivative \( \nabla \) in the tautological vector bundle \( \pi_{S_0,H} \) agrees with the covariant derivative \( \nabla \) in the larger trivial bundle \( \text{Gr}_{S_0}(H) \times H \rightarrow \text{Gr}_{S_0}(H) \), both these covariant derivatives being the ones induced by the reductive structure \( (U(H), U(S_0) \times U(S_0^\perp); E_{\text{PSO}}) \). Consequently it suffices to compute the action of \( \nabla \) on the sections of the subbundle \( \pi_{S_0,H} \), and to this end we use Remark 2.6(3).

If we write the operators on \( H \) as \( 2 \times 2 \) block matrices corresponding to the orthogonal decomposition \( H = S_0 + S_0^\perp \), then

\[
m = u(H) \cap \text{Ker } E_{\text{PSO}} = \left\{ \begin{pmatrix} 0 & R \\ -R^* & 0 \end{pmatrix} \mid R \in B(S_0, S_0^\perp) \right\}
\]

hence for every \( V \in m \) we have \( VS_0 \subseteq S_0^\perp \). Therefore, if we denote by

\[
\beta: T(\text{Gr}_{S_0}(H)) \simeq T(U(H)/(U(S_0) \times U(S_0^\perp))) \rightarrow u(H)
\]

the Maurer-Cartan form for the reductive structure \( (U(H), U(S_0) \times U(S_0^\perp); E_{\text{PSO}}) \), as in Remark 2.6(3), then for every \( X \in T_{S_0}(\text{Gr}_{S_0}(H)) \) we have \( (d\rho_1 \circ \beta)(X)S_0 \subseteq S_0^\perp \). On the other hand for \( \sigma(\cdot) = (\cdot, F_\sigma(\cdot)) \in \Omega^0(\text{Gr}_{S_0}(H), T_{S_0}(H)) \) as in the statement we have \( (\nabla \sigma)(X) = (S_0, (\nabla F_\sigma)(X)) \in \{S_0\} \times S_0 \), hence the equality provided by Remark 2.6(3)

\[
dF_{\sigma}(X) = (\nabla F_{\sigma}(X)) + (d\rho_1 \circ \beta)(X)F_\sigma(S_0)
\]

actually gives the decomposition corresponding to the orthogonal direct sum \( H = S_0 + S_0^\perp \). Therefore \( (\nabla F_{\sigma})(X) = p_{S_0}(dF_{\sigma}(X)) \), and this proves the assertion for \( S = S_0 \) since we have seen above that \( \nabla \) agrees with \( \nabla \).
The formula for the covariant derivative $\nabla$ at another point $S \in \text{Gr}_{S_0}(\mathcal{H})$ then follows by using the transitive action of $U(\mathcal{H})$ on $\text{Gr}_{S_0}(\mathcal{H})$ and the $U(\mathcal{H})$-equivariance property of the Maurer-Cartan form $\beta$, and this completes the proof.

The above Examples 2.9–2.10 will be revisited in Section 5.

3. Reproducing kernels and their classifying morphisms

In this section we begin the developments that will lead up in the next section to the canonical correspondence between the admissible reproducing kernels and the linear connections. More specifically, we will establish the basic properties of the classifying morphisms, which are bundle morphisms into the universal bundles over the Grassmann manifolds of the reproducing kernel Hilbert spaces.

3.1. Reproducing kernels on Hermitian bundles. Geometric models for representations of unitary groups of $C^*$-algebras were obtained in [BR07] by using reproducing kernels associated with suitable homogeneous vector bundles. An approach to these topics in the framework of category theory was carried out in [BG11], which enables us to recover reproducing kernels on Hermitian vector bundles from the universal reproducing kernels on the tautological vector bundles; see Example 3.7 and Theorem 3.9 below.

Definition 3.1. Let $Z$ be a Banach manifold. A Hermitian structure on a smooth Banach vector bundle $\Pi: D \to Z$ is a family $\{(\cdot | \cdot)_z\}_{z \in Z}$ with the following properties:

(a) For every $z \in Z$, $(\cdot | \cdot)_z: D_z \times D_z \to \mathbb{C}$ is a scalar product ($\mathbb{C}$-linear in the first variable) that turns the fiber $D_z$ into a complex Hilbert space.

(b) If $V$ is any open subset of $Z$, and $\Psi_V: V \times \mathcal{E} \to \Pi^{-1}(V)$ is a trivializations (whose typical fiber is the complex Hilbert space $\mathcal{E}$) of the vector bundle $\Pi$ over $V$, then the function $(z, x, y) \mapsto (\Psi_V(z, x) | \Psi_V(z, y))_z, V \times \mathcal{E} \times \mathcal{E} \to \mathbb{C}$ is smooth.

A Hermitian bundle is a bundle endowed with a Hermitian structure as above.

Definition 3.2. Let $\Pi: D \to Z$ be a Hermitian bundle. A reproducing kernel on $\Pi$ is a continuous section of the bundle $\text{Hom}(p_2^*\Pi, p_1^*\Pi) \to Z \times Z$ such that the mappings $K(s, t): D_t \to D_s$ $(s, t \in Z)$ are bounded linear operators and such that $K$ is positive definite in the following sense: For every $n \geq 1$ and $t_j \in Z$, $\eta_j \in D_{t_j} (j = 1, \ldots, n)$,

$$\sum_{j,l=1}^n (K(t_l, t_j)\eta_j \mid \eta_l)_{t_l} \geq 0.$$  \hfill (3.1)

Here $p_1, p_2: Z \times Z \to Z$ are the natural projection mappings.

For every $\xi \in D$ we set $K_{\xi} := K(\cdot, \Pi(\xi))\xi: Z \to D$, which is a section of the bundle $\Pi$. For $\xi, \eta \in D$, the prescriptions

$$(K_\xi \mid K_\eta)_{\mathcal{H}^K} := (K(\Pi(\eta), \Pi(\xi))\xi \mid \eta)_{\Pi(\eta)},$$ \hfill (3.2)

define an inner product $(\cdot \mid \cdot)_{\mathcal{H}^K}$ on $\text{span}\{K_\xi: \xi \in D\}$ whose completion gives rise to a Hilbert space denoted by $\mathcal{H}^K$, which consists of sections of the bundle $\Pi$ (see
We also define the mappings
\[ \hat{K}: D \to \mathcal{H}^K, \quad \hat{K}(\xi) = K\xi, \]
\[ \zeta_K: Z \to \text{Gr}(\mathcal{H}^K), \quad \zeta_K(s) = \hat{K}(D_s), \]
where the bar over \( \hat{K}(D_s) \) indicates the topological closure.

In the following two lemmas we establish some basic properties of the above mappings.

**Lemma 3.3.** In the setting of Definition 3.2, if \( K \) is a smooth section of the bundle \( \text{Hom}(p_2^*\Pi, p_1^*\Pi) \), then the mapping \( \hat{K}: D \to \mathcal{H}^K \) is smooth.

**Proof.** Since both \( K: Z \times Z \to \text{Hom}(p_2^*\Pi, p_1^*\Pi) \) and \( \Pi: D \to Z \) are smooth mappings, it follows by (3.2) that the function
\[ D \times D \to \mathbb{C}, \quad (\xi, \eta) \mapsto (\hat{K}(\xi) | \hat{K}(\eta))_{\mathcal{H}^K} \]
is smooth. Then the assertion follows by [Ne10] Th. 7.1. \( \square \)

**Lemma 3.4.** In the setting of Definition 3.2, the following assertions are equivalent at each \( s \in Z \):

(i) The operator \( \hat{K}|_{D_s}: D_s \to \mathcal{H}^K \) is injective and has closed range.

(ii) The operator \( K(s, s) \in \mathcal{B}(D_s) \) is invertible.

**Proof.** The property that \( \hat{K}|_{D_s}: D_s \to \mathcal{H}^K \) is injective and has closed range is equivalent to the fact that there exists \( c > 0 \) such that for every \( \xi \in D_s \) we have \( \|\hat{K}(\xi)\|_{\mathcal{H}^K} \geq c\|\xi\|_{D_s} \), which is further equivalent to \( (K\xi | K\xi)_{\mathcal{H}^K} \geq c^2\|\xi\|^2_{D_s} \), that is, \( (K(s, s)\xi | \xi)_{D_s} \geq c^2\|\xi\|^2_{D_s} \). The latter condition is equivalent to the fact that \( K(s, s) \) is invertible on \( D_s \), since \( K(s, s) \) is always a bounded nonnegative self-adjoint operator on the complex Hilbert space \( D_s \), as a consequence of (3.1) in Definition 3.2 for \( n = 1 \). \( \square \)

**Definition 3.5.** A reproducing kernel \( K \) on the Hermitian bundle \( \Pi: D \to Z \) is called admissible if it has the following properties:

(a) The kernel \( K \) is smooth as a section of the bundle \( \text{Hom}(p_2^*\Pi, p_1^*\Pi) \).

(b) For every \( s \in Z \) the operator \( K(s, s) \in \mathcal{B}(D_s) \) is invertible.

(c) The mapping \( \zeta_K: Z \to \text{Gr}(\mathcal{H}^K) \) is smooth.

**Example 3.6.** Assume \( \Pi: D \to Z \) is a Hermitian bundle whose fibers are finite dimensional (for instance, \( \Pi \) is a line bundle). If a reproducing kernel \( K \) on \( \Pi \) satisfies the conditions (a)–(b) in Definition 3.5 then it also satisfies the condition (c) hence it is an admissible reproducing kernel.

To prove this, let \( s_0 \in Z \) arbitrary. Since the bundle \( \Pi \) is locally trivial and its fibers are finite-dimensional, it follows by an application of Lemma 3.4 that there exist a positive integer \( n \geq 1 \) and an open neighborhood \( Z_0 \) of \( s_0 \in Z \) such that \( \dim \zeta_K(s) = \dim D_s = n \) for every \( s \in Z_0 \). Then we can use [BG11] Th. 5.5 to obtain that the mapping \( \zeta_K: Z \to \text{Gr}(\mathcal{H}^K) \) is continuous.

Next, for arbitrary \( s_0 \in Z \), \( K(s_0, s_0) \in \mathcal{B}(D_{s_0}) \) is an invertible operator. By considering a local trivialization of \( \Pi \) near \( s_0 \) with the typical fiber \( D_{s_0} \) and using the fact that \( K: Z \times Z \to \text{Hom}(p_2^*\Pi, p_1^*\Pi) \) is continuous, it follows that there exists an open neighborhood \( Z_0 \) of \( s_0 \in Z \) such that for arbitrary \( s, t \in Z_0 \) the operator \( K(s, t) \in \mathcal{B}(D_s, D_s) \) is invertible. Let us define \( \tilde{K}_0: Z_0 \to \mathcal{B}(D_{s_0}, \mathcal{H}^K) \),
\[ \tilde{K}_0(s) = \tilde{K} \circ K(s, s_0). \]
Since \( K : Z \times Z \to \text{Hom}(p_1^* \Pi, p_2^* \Pi) \) is smooth by hypothesis, \( \dim D_{s_0} < \infty \), and \( \tilde{K} : D \to \mathcal{H}^K \) is smooth by Lemma 3.3, it follows that the mapping \( \tilde{K}_0 : Z_0 \to B(D_{s_0}, \mathcal{H}^K) \) is smooth.

Moreover, for arbitrary \( s \in Z_0 \), the operator \( K(s, s_0) \in B(D_{s_0}, D_s) \) is invertible, hence \( \text{Ran} (\tilde{K}_0(s)) = \tilde{K}(D_s) = \zeta_K(s) \). Consequently we have a smooth mapping \( \tilde{K}_0 : Z_0 \to B(D_{s_0}, \mathcal{H}^K) \) with the property that \( \text{Ran} (\tilde{K}_0(\cdot)) : Z_0 \to \text{Gr}(\mathcal{H}^K) \) is continuous. It then follows (see for instance [MS97, Subsect. 1.8 and 1.5]) that the mapping \( \text{Ran}(\tilde{K}_0(\cdot)) \) is smooth, that is, \( \zeta_K|_{Z_0} : Z_0 \to \text{Gr}(\mathcal{H}^K) \) is smooth. Since \( Z_0 \) is a suitably neighborhood of the arbitrary point \( s_0 \in Z \), the proof is complete.

We refer to Proposition 1.2 for examples of admissible reproducing kernels on Hermitian bundles with infinite-dimensional fibers, however we will briefly discuss right now the simplest instance of such a kernel, namely the universal reproducing kernel (cf. [BG11]). It lives on the universal bundle of a complex Hilbert space, which is a basic example of Hermitian vector bundle.

**Example 3.7.** If \( \mathcal{H} \) is a complex Hilbert space, then the universal bundle \( \Pi_{\mathcal{H}} \) has a natural Hermitian structure given by \( (x \mid y)_S := (x \mid y)_{\mathcal{H}} \) for all \( S \in \text{Gr}(\mathcal{H}) \) and \( x, y \in S \). This Hermitian bundle carries a natural reproducing kernel \( Q_{\mathcal{H}} \) defined by

\[ Q_{\mathcal{H}}(S_1, S_2) := p_{S_1} |_{S_2} : S_2 \to S_1 \quad \text{for} \quad S_1, S_2 \in \text{Gr}(\mathcal{H}). \]

Fix an element \( S_0 \in \text{Gr}(\mathcal{H}) \). Then by restriction we obtain the Hermitian vector bundle \( \Pi_{S_0} : T_{S_0}(\mathcal{H}) \to \text{Gr}_{S_0}(\mathcal{H}) \) as a subbundle of \( \Pi_{\mathcal{H}} \). Denote by \( Q_{S_0} \) the restriction of the kernel \( Q_{\mathcal{H}} \) to the bundle \( \Pi_{S_0} \). For every \( S \in \text{Gr}_{S_0}(\mathcal{H}) \) there exists \( u \in \mathcal{U} \) (see Example 2.10) such that \( uS_0 = S \) and \( uS_0^\perp = S_0^\perp \). Then \( up_{S_0} = psu \), that is, \( ps = up_{S_0}u^{-1} \). Thus for all \( u_1, u_2 \in \mathcal{U} \) and \( x_1, x_2 \in S_0 \) we have

\[ Q_{S_0}(u_1S_0, u_2S_0)(u_2x_2) = p_{u_1S_0}(u_2x_2) = u_1psu_2^{-1}u_2x_2. \]

See [BG11, Def. 4.2 and Rem. 4.3] for some more details.

Let \( \Pi : D \to Z \) and \( \Pi : \tilde{D} \to \tilde{Z} \) be Hermitian vector bundles. A **quasimorphism** of \( \Pi \) into \( \Pi \) is a pair \( \Theta = (\delta, \zeta) \), where \( \delta : D \to \tilde{D} \) and \( \zeta : Z \to \tilde{Z} \) are (not necessarily smooth) mappings such that:

(i) \( \zeta \circ \Pi = \Pi \circ \delta; \)

(ii) for every \( z \in Z \) the mapping \( \delta_z := \delta|_{D_z} : D_z \to \tilde{D}_{\zeta(z)} \) is a bounded linear operator.

**Definition 3.8 ([BG11]).** Let \( \Pi : D \to Z \) and \( \Pi : \tilde{D} \to \tilde{Z} \) be Hermitian vector bundles with a quasimorphism \( \Theta = (\delta, \zeta) \) from \( \Pi \) to \( \Pi \). Assume that \( \tilde{K} \) is a reproducing kernel on \( \Pi \). The **pull-back of the reproducing kernel** \( \tilde{K} \) through \( \Theta \) is the reproducing kernel \( \Theta^* \tilde{K} \) on \( \Pi \) defined by

\[ (\forall s, t \in Z) \quad \Theta^* \tilde{K}(s, t) = \delta_s^* \circ \tilde{K}(\zeta(s), \zeta(t)) \circ \delta_t. \tag{3.3} \]

For later use, we now recall from [BG11] the universality theorem for reproducing kernels.

**Theorem 3.9.** Let \( \Pi : D \to Z \) be a Hermitian vector bundle endowed with a reproducing kernel \( K \). If we define \( \delta_K := (\zeta_K \circ \Pi, \tilde{K}) : D \to \mathcal{T}(\mathcal{H}^K) \), then we have the vector bundle quasimorphism \( \Delta_K := (\delta_K, \zeta_K) \) from \( \Pi \) into the universal bundle \( \Pi_{\mathcal{H}^K} \) and moreover \( K = (\Delta_K)^* Q_{\mathcal{H}^K} \).
Proof. See [BG11] Ths. 5.1 and 6.2.

We will call the quasimorphism \( \Delta_K \) constructed in Theorem 3.9 the classifying quasimorphism associated with the kernel \( K \). In order to define the notion of linear connection induced by a reproducing kernel, we need to elucidate when the first component of a classifying quasimorphism is a fiberwise isomorphism. This is done in the next subsection.

3.2. Quantization maps and kernels. Motivated by the significant physical interpretation given in [Od88] and [Od92] (see also [MP97] and [BG11]) to maps from manifolds into the projective space of a complex Hilbert space, we use the following terminology.

Definition 3.10. Let \( Z \) be a Banach manifold and \( \mathcal{H} \) be a complex Hilbert space. Any smooth mapping \( \zeta: Z \to \text{Gr}(\mathcal{H}) \) is termed a quantization map from \( Z \) to \( \mathcal{H} \).

In the framework of Definition 3.10, set \( D_\zeta := \{ (s, x) \in Z \times \mathcal{H} : x \in \zeta(s) \} \).

Then \( D_\zeta \) is a Banach manifold and the projection \( \Pi_\zeta: (s, x) \mapsto s, \quad D_\zeta \to Z \) defines a vector bundle, with local trivializations 
\[
(\Pi_\zeta)^{-1}(\Omega_s) \simeq \Omega_s \times \zeta(s)
\]
for suitably small open subsets \( \Omega_s \subseteq \zeta^{-1}(\text{Gr}_s(\mathcal{H})) \), where \( s \in Z \) and the fiber at \( s \in Z \) is identified to \( \zeta(s) \). Put now 
\[
\psi_\zeta(s, x) := (\zeta(s), x), \quad s \in Z, x \in \zeta(s) \subseteq \mathcal{H},
\]
so that \( (\psi_\zeta, \zeta) \) is a vector bundle morphism from \( \Pi_\zeta: D_\zeta \to Z \) to the universal bundle \( T(\mathcal{H}) \to \text{Gr}(\mathcal{H}) \). In fact, by identifying \( D_\zeta \) with \( \{(s, (\zeta(s), x)) \} | s \in Z, x \in \zeta(s) \} \) one has that \( \Pi_\zeta: D_\zeta \to Z \) is isomorphic to the pull-back of the universal bundle \( T(\mathcal{H}) \to \text{Gr}(\mathcal{H}) \) through the mapping \( \zeta \).

We provide the bundle \( \Pi_\zeta: D_\zeta \to Z \) with the Hermitian structure induced from \( \mathcal{H} \) and with the reproducing kernel given by 
\[
K_\zeta(s, t) := p_{\zeta(s)}|_{\zeta(t)}: \zeta(t) \to \zeta(s) \quad (s, t \in Z).
\]
Clearly, \( K_\zeta(s, s) = \text{id}_{\zeta(s)} \) for every \( s \in Z \). In fact, \( K_\zeta \) is admissible. Firstly, \( \zeta \) is smooth by assumption. Moreover, for every \( S_0 \in \text{Gr}(\mathcal{H}) \) the restriction \( K_\zeta \) on \( \zeta^{-1}(\text{Gr}_{S_0}(\mathcal{H})) \) can be seen as \( Q_{\mathcal{H}, S_0} \circ (\zeta, \zeta) \) and then we can apply to \( Q_{\mathcal{H}, S_0} \) the same argument of part (a) in the proof of Proposition 5.2 below to deduce that \( K_\zeta \) is smooth.

Thus to every quantization map \( \zeta \) there corresponds an admissible reproducing kernel \( K_\zeta \), and it is natural to investigate the correspondence in the opposite direction.

In the following result the bundle \( \Pi_{\zeta_K}: D_{\zeta_K} \to Z \) is endowed with the Hermitian structure and the reproducing kernel \( K_{\zeta_K} \) introduced above.

Theorem 3.11. Let \( \Pi: D \to Z \) be a Hermitian vector bundle with an admissible reproducing kernel \( K \). Then the following assertions hold.
(i) The mapping \( \hat{K} := (\Pi, \hat{K}) \colon D \to \mathcal{D}_{\zeta K} \) is a diffeomorphism and we have the commutative diagram
\[
\begin{array}{ccc}
D & \xrightarrow{\hat{K}} & \mathcal{D}_{\zeta K} \\
\Pi \downarrow & & \downarrow \Pi^{\zeta K} \\
Z & \xrightarrow{\text{id}_Z} & Z
\end{array}
\]
which gives an isomorphism \( \Delta_{\zeta K} := (\hat{K}, \text{id}_Z) \) of smooth vector bundles from \( \Pi \) onto the pull-back of the tautological bundle \( \Pi_{\mathcal{H}K} \) through \( \zeta K \).

(ii) The quasimorphism \( \Delta_K = (\delta_K, \zeta_K) \) of Theorem \ref{thm:main} is smooth and factorizes according to the commutative diagram
\[
\begin{array}{ccc}
\delta_K : D & \xrightarrow{\hat{K}} & \mathcal{D}_{\zeta K} \\
\downarrow \Pi & & \downarrow \Pi^{\zeta K} \\
\zeta_K : Z & \xrightarrow{\text{id}_Z} & Z
\end{array}
\]
where \( \psi_K := \psi_{\zeta K} \) is as after Definition \ref{def:psi}.

(iii) The pull-back relation \( K = \Delta^*_K \zeta K = \Delta^*_K (\psi_K, \zeta_K)^* Q_hK = \Delta^*_K Q_{\mathcal{H}K} \).

**Proof.** (i) It follows by Lemma \ref{lem:smoothness} that \( \hat{K} \) is smooth, hence also \( \hat{K} \) is smooth.

To prove that \( \hat{K} \) is bijective, first suppose that \( \xi, \eta \in D \) and \( \hat{K}(\xi) = \hat{K}(\eta) \). This means that \( \Pi(\xi) = s = \Pi(\eta) \), with \( s \in Z \), and therefore \( \xi, \eta \in D_s \). Since \( \hat{K} \) is injective on \( D_s \) by Lemma \ref{lem:injectivity} we deduce that \( \xi = \eta \). Now, take an element \( (s, x) \) with \( s \in Z \) and \( x \in \zeta_K(s) = \hat{K}(D_s) \), where the equality of these two subsets holds because \( \hat{K}(D_s) \) is closed by Lemma \ref{lem:closed}. Thus there exists \( \xi \in D_s \) such that \( x = \hat{K}(\xi) \) and therefore \( (s, x) = (\Pi(\xi), \hat{K}(\xi)) \). We have proved that \( \hat{K} \) is both injective and surjective. In conclusion, \( \hat{K} \) is a bijection between the bundles \( D \) and \( \mathcal{D}_{\zeta K} \), and the fact that \( \Delta_{\zeta K} \) is a vector bundle morphism follows readily.

Moreover, since \( \hat{K} : D_s \to \hat{K}(D_s) \) is continuous for every \( s \in Z \), it follows by Lemma \ref{lem:open_mapping} that we can use the open mapping theorem to obtain that \( \hat{K} \) is a fiberwise topological isomorphism. Since \( \hat{K} \) is an admissible reproducing kernel, it follows that the mapping \( \zeta_K : D \to \text{Gr}(\mathcal{H}K) \) is smooth, and then the discussion after Definition \ref{def:psi} provides local trivializations for the bundle \( \Pi^{\zeta K} : \mathcal{D}_{\zeta K} \to Z \). It then follows that \( \hat{K} \) is represented locally (as in [La01, Ch. III, §1, VB Mor 2]) by a smooth mapping with values invertible operators on the typical fiber, and then its pointwise inverse is also smooth. This shows that the inverse mapping of the bijection \( \hat{K} \) is also smooth, hence \( \hat{K} \) is a diffeomorphism.

(ii) Straightforward consequence of (i), since \( \psi_K \circ (\Pi, \hat{K}) = (\zeta_K, \hat{K}) = \delta_K \).

(iii) The proof is similar to the one of Theorem \ref{thm:main} by also using \( (\psi_K, \zeta_K)^* \delta_{\zeta K} = (\psi_K, \zeta_K) \circ (\Pi, \hat{K}), \text{id}_Z \) and \( (\psi_K \circ (\Pi, \hat{K}), \zeta_K) = (\delta_K, \zeta_K) = \Delta_K \).

4. Connections associated with reproducing kernels

**4.1. Linear connections induced by reproducing kernels.** Let \( \Pi : D \to Z \) be a Hermitian vector bundle endowed with an admissible reproducing kernel \( K \). Let \( \Delta_K = (\delta_K, \zeta_K) \) be the classifying quasimorphism for \( K \) constructed in Theorem \ref{thm:main} which is smooth by Theorem \ref{thm:smoothness} since \( K \) is supposed to be admissible. Assume
for a moment that \( S_0 \) in \( \text{Gr}(H^K) \) is such that \( \zeta_K(Z) \subseteq \text{Gr}_{S_0}(H^K) \) (it holds for instance if \( Z \) is connected), and therefore \( \delta_K(D) \subseteq T_{S_0}(H^K) \), so \( \Delta_K \) is a morphism from \( \Pi \) to the universal bundle \( \Pi_{S_0} \) at \( S_0 \subseteq H^K \):

\[
\begin{array}{ccc}
D & \xrightarrow{\delta_K} & T_{S_0}(H^K) \\
\Pi & \downarrow & \downarrow \Pi_{H^K,S_0} \\
Z & \xrightarrow{\zeta_K} & \text{Gr}_{S_0}(H^K)
\end{array}
\]

Let \( E_p \) be the conditional expectation naturally associated to the orthogonal projection \( p := p_{S_0} : H^K \to S_0 \). Then let \( \Phi_{S_0} \) denote the connection induced by \( E_p \) on the bundle \( \Pi_{H^K,S_0} \) as in Definition 2.11 i.e.,

\[
\Phi_{S_0} : \{(u,X),(x,y)\} \mapsto \{(u,0),(x,E_pXx+y)\}.
\]

Since we are assuming that \( K(s,s) \) is invertible on \( D_s \) for all \( s \in Z \), we have that the map \( \delta_K \) is a fiberwise linear isomorphism from \( D_s \) onto \( \hat{K}(D_s) \) and then the following definition is consistent, according to Proposition A.9.

**Definition 4.1.** Under the above conditions, we call connection induced by the admissible reproducing kernel \( K \) the pull-back connection \( \Phi_K \) on \( \Pi \) given by

\[
\Phi_K := (\Delta_K)^*(\Phi_{S_0}).
\]

Note that condition \( \zeta_K(Z) \subseteq \text{Gr}_{S_0}(H^K) \), as prior to the definition, may always be assumed without loss of generality since, otherwise, one can consider partitioning \( D \) into the (open) submanifolds \( \zeta_K^{-1}(\text{Gr}_{S_0}(H^K)) \), define the connection on each of them, and then define the global connection on \( D \) piecewise.

We compute now the covariant derivative for the connection induced by a reproducing kernel in the framework of Definition 4.1.

**Theorem 4.2.** In the setting of Definition 4.1 let \( \nabla_K : \Omega^0(Z,D) \to \Omega^1(Z,D) \) be the covariant derivative for the connection induced by \( K \).

If \( \sigma \in \Omega^0(Z,D) \) has the property that there exists \( \tilde{\sigma} \in \Omega^0(\text{Gr}_{S_0}(H^K),T_{S_0}(H^K)) \) such that \( \delta_K \circ \sigma = \tilde{\sigma} \circ \zeta_K \), then for \( s \in Z \) and \( X \in T_sZ \) we have

\[
(\nabla \sigma)(X) = K(s,s)^{-1}(\langle p_{\zeta_K(s)}(d(\hat{K} \circ \sigma)(X)) \rangle)(s).
\]

An equivalent way of expressing the conclusion of Theorem 4.2 is that for \( s \in Z \), \( t_0 > 0 \), \( \gamma \in C^\infty((-t_0,t_0),Z) \) with \( \gamma(0) = s \) and \( \sigma \in \Omega^0(Z,D) \) we have the formula

\[
(\nabla \sigma)(\gamma(0)) = K(s,s)^{-1}(p_{\zeta_K(s)}(d \bigg|_{t=0} \hat{K}(\sigma(\gamma(t)))\bigg))(s)
\]

which only requires the derivative at \( t = 0 \) of the function \( \hat{K} \circ \sigma \circ \gamma : (-t_0,t_0) \to H^K \) and then to take the orthogonal projection of the derivative on the subspace \( \zeta_K(s) \) of \( H^K \).

**Proof of Theorem 4.2.** Recall that for every \( \xi \in D \) we have

\[
\hat{K}(\xi) = K_\xi = K(\cdot, \Pi(\xi))\xi \quad \text{and} \quad \delta_K(\xi) = (\zeta_K(\Pi(\xi)), \hat{K}(\xi)).
\]

Let \( s \in Z \) and \( X \in T_sZ \) arbitrary.
Since \( \delta_K \circ \sigma = \tilde{\sigma} \circ \zeta_K \), it follows by Proposition \[\text{A.2}\] that \( \delta_K \circ \nabla \sigma = \tilde{\nabla} \sigma \circ T(\zeta_K) \), where \( \tilde{\nabla} \) denotes the covariant derivative for the universal connection on the tautological vector bundle \( \Pi_{\mathcal{H},S_0} : T_{S_0}(\mathcal{H}^K) \to \text{Gr}_{S_0}(\mathcal{H}^K) \). In particular

\[
(\zeta_K(s), \hat{K}((\nabla \sigma)(X))) = \delta_K((\nabla \sigma)(X)) = \tilde{\nabla} \sigma(T(\zeta_K)X). \quad (4.1)
\]

On the other hand, since \( \tilde{\sigma} \in \Omega^0(\text{Gr}_{S_0}(\mathcal{H}^K), T_{S_0}(\mathcal{H}^K)) \), there exists a uniquely determined function \( F_{\tilde{\sigma}} \in C^\infty(\text{Gr}_{S_0}(\mathcal{H}^K), \mathcal{H}^K) \) with \( \tilde{\sigma}(\cdot) = (, F_{\tilde{\sigma}}(\cdot)) \). Then by Proposition \[\text{2.13}\] we obtain

\[
\tilde{\nabla} \sigma(T(\zeta_K)X) = (\zeta_K(s), p_{\zeta_K(s)}(dF_{\tilde{\sigma}}(T(\zeta_K)X))). \quad (4.2)
\]

By using \( \delta_K \circ \sigma = \tilde{\sigma} \circ \zeta_K \) again, we obtain \( F_{\tilde{\sigma}} \circ \zeta_K = \hat{K} \circ \sigma : Z \to \mathcal{H}^K \), hence by differentiation we obtain

\[
dF_{\tilde{\sigma}} \circ T(\zeta_K) = d(\hat{K} \circ \sigma). \quad (4.3)
\]

It now follows by (4.1)–(4.3) that

\[
\hat{K}((\nabla \sigma)(X)) = p_{\zeta_K(s)}(d(\hat{K} \circ \sigma)(X)) \in \mathcal{H}^K.
\]

Both sides of the above equality are sections in the bundle \( \Pi : D \to Z \), and moreover \( (\nabla \sigma)X \in D_{\sigma} \). By evaluating the left-hand side at the point \( s \in Z \) we obtain the value \( K(s, s)((\nabla \sigma)X) \in D_{\sigma} \). Hence by evaluating both sides of the above equality at \( s \) and then applying the operator \( K(s, s)^{-1} \) to both sides of the equality obtained after the evaluation we obtain \( (\nabla \sigma)(X) = K(s, s)^{-1}(p_{\zeta_K(s)}(d(\hat{K} \circ \sigma)(X)))(s) \), as we wanted to show. \( \square \)

4.2. Categorial aspects. We will now discuss the functorial features of the above correspondence between reproducing kernels and linear connections, and it will follow that this correspondence is unique in a quite natural way. The precise statement actually concerns the relationship between various categories:

- **Hilb** is the category whose objects are the complex Hilbert spaces and the morphisms are the linear isometries.
- **Herm** is the category whose objects are the Hermitian vector bundles and the morphisms are the bundle morphisms which are fiberwise unitary operators;
- **Kernh** is the category whose objects are the admissible reproducing kernels on Hermitian bundles. The morphisms of this category are defined by

\[
\text{Hom}_{\text{Kernh}}(K_1, K_2) = \{ \Theta \in \text{Hom}_{\text{Herm}}(\Pi_1, \Pi_2) \mid \Theta^*(K_2) = K_1 \}
\]

whenever \( K_j \) is an admissible reproducing kernel on the Hermitian vector bundle \( \Pi_j \) for \( j = 1, 2 \). The morphisms \( \Theta = (\delta, \zeta) \) in \( \text{Hom}_{\text{Kernh}}(K_1, K_2) \) satisfy that \( \delta \) is a fiberwise diffeomorphism. This follows from the identity \( K_1(t, t) = \delta^* \circ K_2((\zeta(t), \zeta(t))) \circ \delta, t \in Z_1 \), where \( \Pi_1 : D_1 \to Z_1 \), since \( K_1, K_2 \) are admissible.

- **LinConnect** is the category whose objects are the linear connections on Hermitian vector bundles and the morphisms are defined by

\[
\text{Hom}_{\text{LinConnect}}(\Phi_1, \Phi_2) = \{ \Theta \in \text{Hom}_{\text{Herm}}(\Pi_1, \Pi_2) \mid \Theta^*(\Phi_2) = \Phi_1 \}
\]

whenever \( \Phi_j \) is a linear connection on the Hermitian vector bundle \( \Pi_j \) for \( j = 1, 2 \). Note that a morphism \( \Theta \) in \( \text{Hom}_{\text{LinConnect}}(\Phi_1, \Phi_2) \) must be fiberwise diffeomorphic for the condition \( \Theta^*(\Phi_2) = \Phi_1 \) to make sense.
• $Q: \text{Hilb} \to \text{Kernh}$ is the functor that constructs the universal reproducing kernel on the tautological bundle for a given Hilbert space.
• $\Phi: \text{Hilb} \to \text{LinConnect}$ is the functor that constructs the universal connection on the tautological bundle for a given Hilbert space.
• $F$ are the forgetful functors that associate to every kernel or connection the bundle where these objects are living.
• And finally, $A: \text{Kernh} \to \text{LinConnect}$ is the functor defined by means of Definition 4.1 on the level of objects of these categories and which acts identically on the level of morphisms.

Here is the categorial characterization of the functor $A$ from the category of the admissible reproducing kernels to the one of linear connections on Hermitian vector bundles.

**Theorem 4.3.** There exists a unique functor from $\text{Kernh}$ into $\text{LinConnect}$ such that the diagram

![Diagram](image)

is commutative, and that functor is $A: \text{Kernh} \to \text{LinConnect}$.

**Proof.** We first check that the diagram in the statement is commutative if the role of the dotted arrow is played by the functor $A$. In fact, we have $F \circ A = F$ since the functor $A$ takes an admissible reproducing kernel on some Hermitian vector bundle to a linear connection on the same Hermitian vector bundle. Moreover, it follows directly by Definition 4.1 (see also [BG08, Prop. 4.1], [BG09, Prop. 4.5 and Ex.]) that $A \circ Q = \Phi$.

To prove the uniqueness assertion, let us assume that $B: \text{Kernh} \to \text{LinConnect}$ is a functor such that $F \circ B = F$ and $B \circ Q = \Phi$. The latter equality shows that for every Hilbert space $H$ we have $B(Q_H) = \Phi_H$, hence $B(Q_H) = A(Q_H)$. Thus the functors $B$ and $A$ agree on the universal reproducing kernels.

Now let $K$ be an arbitrary admissible reproducing kernel on a Hermitian vector bundle $\Pi$. The classifying morphism $\Delta_K \in \text{Hom}_{\text{Herm}}(\Pi, T(\mathcal{H}_K))$ has the property $\Delta_K^*(Q_{\mathcal{H}_K}) = K$, hence we have $\Delta_K \in \text{Hom}_{\text{Kernh}}(K, Q_{\mathcal{H}_K})$. By using the functor $B: \text{Kernh} \to \text{LinConnect}$, it follows $B(\Delta_K) \in \text{Hom}_{\text{LinConnect}}(B(K), B(Q_{\mathcal{H}_K}))$.

On the other hand, by using the equality $F \circ B = F$ on morphisms in the category $\text{Kernh}$, we get $B(\Delta_K) = \Delta_K$; moreover, we established above that $B(Q_H) = \Phi_H$ for every Hilbert space $\mathcal{H}$, hence in particular $B(Q_{\mathcal{H}_K}) = \Phi_{\mathcal{H}_K}$. We thus obtain $\Delta_K \in \text{Hom}_{\text{LinConnect}}(B(K), \Phi_{\mathcal{H}_K})$. By the definition of the morphisms in the category $\text{LinConnect}$, this means that $B(K) = \Delta_K^*(\Phi_{\mathcal{H}_K})$, hence we have $B(K) = A(K)$. Thus the functors $B$ and $A$ agree on the level of objects in the category $\text{Kernh}$.

Furthermore, it follows by the condition $F \circ B = F$ that the functor $B$ acts identically on the morphisms of the category $\text{Kernh}$, just as the functor $A$ does. Thus eventually $B = A$. \qed
5. Examples

We will discuss here the linear connections associated with three types of examples, namely the usual operator-valued reproducing kernels (Subsection 5.1), then the reproducing kernels on homogeneous vector bundles that occur in the geometric representation theory of Banach-Lie groups (Subsection 5.2), and finally the reproducing kernels related to the dilation theory of completely positive mappings (Subsection 5.3).

5.1. Reproducing kernels on trivial bundles. We illustrate here the theory established in the preceding sections by giving some results involving classical reproducing kernels on trivial vector bundles.

(a) General case.
Let $\mathcal{X}$ be a set and $\mathcal{V}$ be a complex Hilbert space. Assume that $\kappa: \mathcal{X} \times \mathcal{X} \to \mathcal{B}(\mathcal{V})$ is the reproducing kernel of a Hilbert space denoted by $\mathcal{H}^{\kappa}$. This means in particular that, for every $x_i \in \mathcal{X}$, $v_i \in \mathcal{V}$, $i = 1, \ldots, n$,
\[ \sum_{i,j=1}^{n} (\kappa(x_i, x_j) v_j | v_i)_{\mathcal{V}} \geq 0, \]
and that $\mathcal{H}^{\kappa}$ is the Hilbert space of $\mathcal{V}$-valued functions on $\mathcal{X}$ generated by the space $\text{span}\{\kappa_x \otimes v : x \in \mathcal{X}, v \in \mathcal{V}\}$, where
\[ \kappa_x \otimes v := \kappa(\cdot, x)v: \mathcal{X} \to \mathcal{V}, \]
with respect to the inner product given by
\[ (\kappa_x \otimes v | \kappa_y \otimes w)_{\mathcal{H}^{\kappa}} := (\kappa(y, x)v | w)_{\mathcal{V}}, \]
see [Ne00, Theorem I.1.4, (2) and (a)].

In the sequel we assume that $\mathcal{X}$ is a Banach manifold, with $\kappa$ smooth, such that $\kappa(x, x)$ is invertible in $\mathcal{B}(\mathcal{V})$ for all $x$, which corresponds to a reproducing kernel on the trivial Hermitian bundle $\mathcal{X} \times \mathcal{V} \to \mathcal{X}$. In this special case we now compute the covariant derivative for the connection induced by the reproducing kernel $K$ when moreover $\dim \mathcal{V} = 1$, hence we may assume $\mathcal{V} = \mathbb{C}$. In the following statement we use subscripts to denote the values of differential 1-forms on $\mathcal{X}$.

Proposition 5.1. For every smooth section $\sigma(\cdot) = (\cdot, F_\sigma(\cdot))$ of the trivial bundle $\mathcal{X} \times \mathbb{C} \to \mathcal{X}$, where $F_\sigma \in C^\infty(\mathcal{X}, \mathbb{C})$, we have
\[ (\forall x \in \mathcal{X}) \quad (\nabla \sigma)_x = (x, (dF_\sigma)_x + F_\sigma(x) \frac{\partial_2 \kappa(x, x)}{\kappa(x, x)}) \in \{x\} \times \mathcal{B}(T_x \mathcal{X}, \mathbb{C}). \]

Hence the covariant derivative $\nabla$ can be identified with the first order linear differential operator $\nabla: \Omega^0(\mathcal{X}, \mathbb{C}) \to \Omega^1(\mathcal{X}, \mathbb{C})$ defined by
\[ (\forall F \in C^\infty(\mathcal{X}, \mathbb{C})) \quad \nabla F = dF + \alpha_\kappa \cdot F, \]
where the differential 1-form $\alpha_\kappa \in \Omega^1(\mathcal{X}, \mathbb{C})$ is defined by $(\alpha_\kappa)_x = \frac{\partial_2 \kappa(x, x)}{\kappa(x, x)}$ for all $x \in \mathcal{X}$.

Proof. For arbitrary $x \in \mathcal{X}$ we have $\zeta_\kappa(x) = \mathbb{C} \cdot \kappa_x$, where $\kappa_x = \kappa(\cdot, x) \in \mathcal{H}^{\kappa}$ and $(\kappa_x | \kappa_x)_{\mathcal{H}^{\kappa}} = \kappa(x, x)$. Therefore
\[ (\forall x \in \mathcal{X}) \quad p_{\zeta_\kappa(x)} = \frac{(\cdot | \kappa_x)}{\kappa(x, x)} \kappa_x. \]
Moreover
\[(\forall x \in \mathcal{X})(\forall v \in \mathbb{C}) \quad \tilde{K}(x, v) = v \kappa_x = v \kappa(\cdot, x).\]

Now consider a smooth path \(\gamma \in C^\infty((-t_0, t_0), \mathcal{X})\) with \(\gamma(0) = x \in \mathcal{X}\) and a smooth section \(\sigma(\cdot) = (\cdot, F_\sigma(\cdot)), \) where \(F_\sigma \in C^\infty(\mathcal{X}, \mathbb{C})\). For arbitrary \(t \in (-t_0, t_0)\) we have
\[
\tilde{K}(\sigma(\gamma(t))) = \tilde{K}(\gamma(t), F_\sigma(\gamma(t))) = F_\sigma(\gamma(t)) \kappa(\cdot, \gamma(t)) = F_\sigma(\gamma(t)) \kappa_\gamma(t) \text{ and}
\]
\[
p_{\zeta_{K}(x)}(\tilde{K}(\sigma(\gamma(t)))) = \frac{\tilde{K}(\sigma(\gamma(t))) | \kappa_x \kappa_x}{\kappa(x, x)} = \frac{F_\sigma(\gamma(t)) \kappa(x, \gamma(t))}{\kappa(x, x)} \kappa_x
\]

hence
\[
\left.\frac{d}{dt}\right|_{t=0} p_{\zeta_{K}(x)}(\tilde{K}(\sigma(\gamma(t)))) = \left(\frac{dF_\sigma(\gamma(0)) + F_\sigma(x) \frac{\partial_2 \kappa(x, x)}{\kappa(x, x)} (\gamma(0))}{\kappa(x, x)}\right) \kappa_x.
\]

Therefore, by using Theorem 4.2 it follows that for any smooth section \(\sigma(\cdot) = (\cdot, F_\sigma(\cdot)), \) where \(F_\sigma \in C^\infty(Z, \mathbb{C}), \) we have
\[
(\forall x \in \mathcal{X}) \quad (\nabla \sigma)_x = (x, (dF_\sigma)_x + F_\sigma(x) \frac{\partial_2 \kappa(x, x)}{\kappa(x, x)}) \in \{x\} \times \mathcal{B}(T_x \mathcal{X}, \mathbb{C})
\]
as we wanted to show. \(\square\)

We next recall a few classical reproducing kernels on one-dimensional trivial vector bundles arising in function theory, so that their linear connections can be computed using the above formula (5.1).

(b) Classical (scalar-valued) reproducing kernels: Bergman and Hardy spaces on the disk and the half-plane; Fock space.

(b.1) For \(\nu > 1\), the corresponding Bergman space is the Hilbert space
\[
\mathcal{B}_2^\nu(\mathbb{D}) = \left\{ f \in \mathcal{O}(\mathbb{D}) \left| \frac{\nu - 1}{\pi} \int_{\mathbb{D}} |f(z)|^2 (1 - |z|^2)^{\nu - 2} \, dz < \infty \right. \right\},
\]
where \(dz\) is the Lebesgue measure on \(\mathbb{D}\). Clearly, the polynomial functions belong to \(\mathcal{B}_2^\nu(\mathbb{D})\). In the “limiting case” \(\nu = 1\) one obtains the Hardy space
\[
\mathcal{H}_2^\nu(\mathbb{D}) = \left\{ f \in \mathcal{O}(\mathbb{D}) \left| \sup_{0 < r < 1} \frac{1}{2\pi} \int_0^{2\pi} |f(re^{i\theta})|^2 \, d\theta < \infty \right. \right\}.
\]
Let us denote for a while both the Bergman and Hardy spaces on the unit disk by the same symbol \(\mathcal{H}_\nu(\mathbb{D}), \nu \geq 1\) (the Hardy space corresponds to \(\nu = 1\)). These are reproducing kernel Hilbert spaces with kernels
\[
K_\mathbb{D}^{(\nu)}(s, t) = \frac{1}{(1 - \overline{s}t)^\nu} \quad (s, t \in \mathbb{D}; \nu \geq 1);
\]
see [HI08, Ne00], for instance.

In a similar way, for the upper halfplane \(\mathbb{U} := \{ z \in \mathbb{C} : \Im z > 0 \}, \) define the Bergman space
\[
\mathcal{B}_2^\nu(\mathbb{U}) = \left\{ F \in \mathcal{O}(\mathbb{U}) \left| \frac{\nu - 1}{\pi} \int_{\mathbb{D}} |F(z)|^2 (\Im z)^{\nu - 2} \, dz < \infty \right. \right\}.
\]
It turns out that $\mathfrak{B}_z^2(\mathbb{U})$ is unitarily equivalent to $\mathfrak{B}_z^2(\mathbb{D})$ through the Cayley transform $\varphi(z) := \frac{z - i}{z + i}$, $(z \in \mathbb{U})$. The reproducing kernel of $\mathfrak{B}_z^2(\mathbb{U})$ is given by

$$K^{(\nu)}_U(z, w) := \frac{1}{4} \frac{(2i)^\nu}{(z - w)^\nu}, \quad (z, w \in \mathbb{U});$$

see [Hi08] p. 16. The Hardy space on $\mathbb{U}$,

$$\mathfrak{H}_2(\mathbb{U}) = \left\{ F \in \mathcal{O}(\mathbb{U}) \bigg| \sup_{y > 0} \frac{1}{2\pi} \int_{-\infty}^{\infty} |F(x + iy)|^2 dx < \infty \right\},$$

is also a reproducing kernel Hilbert space with kernel

$$K^{(1)}_U(z, w) := \frac{i}{2(z - w)}, \quad (z, w \in \mathbb{U});$$

see [Hi08] p. 19.

Unlike the Bergman case, the image of $\mathfrak{H}_2(\mathbb{U})$ via the unitary isomorphism induced by the Cayley transform $\varphi$ is not all of $\mathfrak{H}_2(\mathbb{D})$, but just a closed proper subspace of it, see [Ho62] Ch. 8. Despite this, we use the symbol $\mathcal{H}_\nu(\mathbb{U})$ to refer both the Bergman and the Hardy spaces on $\mathbb{U}$. As in the unit disk case, the Hardy space corresponds to $\nu = 1$.

We should note that in the above expressions of the kernels we omitted the number $1/\pi$ that occurs in the expressions given in [Hi08], since we preferred to keep it in the integral conditions defining the Bergman and Hardy spaces.

(b.2) Let $E$ be a complex vector space and let $\beta : E \times E \to \mathbb{C}$ be a positive semidefinite hermitian form on $E$. Then $K_{\mathcal{F}, \beta}(z, w) := e^{\beta(z, w)}$, for $z, w \in E$, is a reproducing kernel which generates a Hilbert space $\mathcal{H}_{\mathcal{F}, \beta}$ denoted by $\mathcal{F}(E, \beta) := \mathcal{H}_{\mathcal{F}, \beta}$, and which is called Fock space associated with $E$ and $\beta$. See [Ne00] p. 38.

When $E = \mathbb{C}^n$ is finite-dimensional, the Fock space can be realized as

$$\mathcal{F}(E, \beta) = \left\{ F \in \mathcal{O}(E) \bigg| \frac{1}{\pi^n} \int_E |F(z)|^2 e^{-\beta(z, z)} dz < \infty \right\}.$$

See for instance [Hi08] pp. 25, 26.

On account of the above examples, the former point (a) applies to:

1. The set $\mathcal{X} := \mathbb{D}$, the Hilbert spaces $\mathcal{V} := \mathbb{C}$ and $\mathcal{H}^\kappa := \mathcal{H}_\nu(\mathbb{D})$, with the trivial bundle $\mathbb{D} \times \mathbb{C} \to \mathbb{D}$ and kernel $\kappa := K^{(\nu)}_\mathbb{D}$.

2. $\mathcal{X} := \mathbb{U}$, $\mathcal{V} := \mathbb{C}$ and $\mathcal{H}^\kappa := \mathcal{H}_\nu(\mathbb{U})$, with trivial bundle $\mathbb{U} \times \mathbb{C} \to \mathbb{U}$ and kernel $\kappa := K^{(\nu)}_\mathbb{U}$.

3. $\mathcal{X} := \mathcal{E}$, $\mathcal{V} := \mathbb{C}$ and $\mathcal{H}^\kappa := \mathcal{F}(E, \beta)$, with trivial bundle $\mathcal{E} \times \mathbb{C} \to \mathcal{E}$ and kernel $\kappa := K_{\mathcal{F}, \beta}$. (The prototypical example of Fock space occurs when $E = \mathbb{C}^n$ and $\beta(z, w) = \sum_{j=1}^n z_j w_j$, $z = (z_1, \ldots, z_n), w = (w_1, \ldots, w_n) \in \mathbb{C}^n$, $n \in \mathbb{N}$; see [Ne00] p. 10.)

It is straightforward to compute the first-order differential operator $(5.1)$ in this case, in any of the above examples:

1. For $K^{(\nu)}_\mathbb{U}(s, t) = (1 - ts)^{-\nu}$ generating $\mathcal{H}_\nu(\mathbb{D})$, $\nu \geq 1$, we have

$$(\nabla s)_s(z) = dF_s(z) - \nu sF_s(s) \frac{\overline{z}}{1 - |s|^2}$$

for $s \equiv F_s \in \mathbb{C}^\infty(\mathbb{D}, \mathbb{C})$, $s \in \mathbb{D}$, $z \in \mathbb{C}$. 

(2) For $K^{(\nu)}_\psi(z, w) = \frac{1}{\pi} (2i)^\nu (z - \overline{w})^{-\nu}$ generating $\mathcal{H}_\nu(U)$, $\nu \geq 1$, we have

$$(\nabla \sigma)_\lambda = dF_\sigma(\lambda) - \frac{\nu F_\sigma(z)}{\text{Im} z} \lambda$$

for $\sigma \equiv F_\sigma \in \mathbb{C}^\infty(U, \mathbb{C})$, $z \in \mathbb{D}, \lambda \in \mathbb{C}$.

(3) For $K_{\mathcal{F}, \beta}(z, w) = \exp(\sum_{j=1}^n z_j \overline{w}_j)$, $z, w \in \mathbb{C}^n$, generating the Fock space on $\mathbb{C}^n$, one gets

$$(\nabla \sigma)_\lambda = dF_\sigma(\lambda) + F_\sigma(z) \sum_{j=1}^n z_j \lambda_j$$

for $\sigma \equiv F_\sigma \in \mathbb{C}^\infty(\mathbb{C}^n, \mathbb{C})$, $z = (z_j)_{j=1}^n, \lambda = (\lambda_j)_{j=1}^n \in \mathbb{C}^n$.

5.2. Reproducing kernels on homogeneous vector bundles. Let $G_A$ be a Banach-Lie group with a Banach-Lie subgroup $G_B$. Let $\rho_A: G_A \to \mathcal{B}(\mathcal{H}_A)$ and $\rho_B: G_B \to \mathcal{B}(\mathcal{H}_B)$ be uniformly continuous unitary representations with $\mathcal{H}_B \subseteq \mathcal{H}_A$, $\rho_B(g) = \rho_A(g)|_{\mathcal{H}_B}$ for $g \in G_B$ and $\mathcal{H}_A = \bigoplus_{\nu=0}^\infty \rho_A(G_A)\mathcal{H}_B$.

Let us consider the homogeneous vector bundle $\Pi_\rho: G_A \times_{G_B} \mathcal{H}_B \to G_A/G_B$, induced by the representation $\rho_B$. We endow $\Pi_\rho$ with the Hermitian structure given by

$$[[u, f], [(u, h)]]_s := (f | h)_{\mathcal{H}}, \quad u \in G_A, s := uG_B, f, h \in \mathcal{H}_B.$$
Proposition 5.4. As the following result shows.

Definition 5.3. Since \( K \) is admissible, both these mappings are smooth by Theorem 3.11. In the following we will describe the linear connection associated with the admissible reproducing kernel \( K \).

Proof. Recall from Theorem 2.2 that \( \Phi_{E_p} \) is given by

\[
[(u,Y),(f,h)] \mapsto [(u,0),(E_p(Y)f + h)]
\]

for \( u \in U(\mathcal{H}_A), Y \in \mathcal{B}(\mathcal{H}_A) \) and \( f,h \in \mathcal{H}_B \). On the other hand, the tangent map \( T\delta_p \) is given by

\[
T\delta_p : [(g,X),(f,h)] \mapsto [(\rho(g),d\rho(X)),(f,h)],
\]

for \( g \in G_A, X \in \mathfrak{g}_A, f,h \in \mathcal{H}_B \). Thus the composition \( \Phi = (T\delta_p)^{-1} \circ \Phi_{E_p} \circ T\delta_p \) is

\[
\Phi : [(g,X),(f,h)] \mapsto [(g,0),(f,E_p(d\rho(X))f + h)].
\]

Finally, since \( E_p(d\rho(X))f = P(d\rho(X)f) \), we obtain that \( \Phi = \Phi_p \) as claimed.

Corollary 5.5. For \( \delta_{K_p} \) and \( \zeta_{K_p} \) as above, the connection \( \Phi_{K_p} \) associated with \( K_p \) on the homogeneous vector bundle \( \Pi : G_A \times_{G_B} \mathcal{H}_B \to G_A/G_B \) in the sense of Definition 4.1 coincides with the natural connection \( \Phi_p \) on \( \Pi \) given by Definition 5.3.
Proposition 5.6. Let \( \phi: G_A \rightarrow \mathcal{H}_B \) be smooth such that \( \phi(uw) = \rho_A(w)^{-1}\phi(u) \) for all \( u \in G_A \) and \( w \in G_B \) and define the corresponding smooth section \( \sigma: G_A / G_B \rightarrow \pi^*\mathcal{H}_B \) by \( \sigma(uG_B) := [(u, \phi(u))] \) for all \( u \in G_A \). If there exists a smooth section \( \tilde{\sigma}: \mathrm{Gr}_{\mathcal{H}_B}(\mathcal{H}_A) \rightarrow \pi_\mathcal{H}_B(\mathcal{H}_A) \) such that \( \tilde{\sigma}(\rho_A(u)\mathcal{H}_B) := (\rho_A(u)\mathcal{H}_B, \rho_A(u)\phi(u)) \) for all \( u \in G_A \), then for every tangent vector \( [(u, X)] \in G_A \times G_B \mathfrak{m} = T(G_A / G_B) \) we have

\[
(\nabla \sigma)([(u, X)]) = [(u, d\phi(u, X) + \varphi(uG_A X\phi(u))]].
\]

Proof. Denote \( Z = G_A / G_B \), and let \( s = uG_B \in Z \) and \( X \in T_s Z \) arbitrary. Let \( h \in \mathcal{H}_B \) such that \( (\nabla \sigma)X := (\nabla \sigma)([(u, X)]) = [(u, h)] \). Since \( \delta_\rho \circ \sigma = \tilde{\sigma} \circ \zeta_\rho \), it follows by Propositions [5,4] and [A,4] that \( \delta_\rho \circ \nabla \sigma = \nabla \tilde{\sigma} \circ T(\zeta_\rho) \), \( \nabla \tilde{\sigma}(T(\zeta_\rho)) = (\rho_A(u)\mathcal{H}_B, \rho_A(u)\phi(u)). \)

Let \( F_\sigma \in C^\infty(\mathrm{Gr}_{\mathcal{H}_B}(\mathcal{H}_A), \mathcal{H}_A) \) such that \( F_\sigma(\rho_A(u)\mathcal{H}_B) = \rho_A(u)\phi(u) \) for all \( u \in G_A \), so that \( \tilde{\sigma}(\cdot) = (\cdot, F_\sigma(\cdot)) \). Then by Proposition [2,13] we obtain

\[
\nabla \tilde{\sigma}(T(\zeta_\rho)) = (\rho_A(u)\mathcal{H}_B, \rho_A(u)\mathcal{H}_B) = (\rho_A(u)\mathcal{H}_B, \rho_A(u)\phi(u) + d\rho_A(X)\phi(u) + d\phi(u, X))].
\]

Let \( \mathcal{R} \) denote the second component of \( \delta_\rho \) (as in [BG11]). By using the equality \( \delta_\rho \circ \sigma = \tilde{\sigma} \circ \zeta_\rho \) again, we get \( F_\sigma \circ \zeta_\rho = \mathcal{R} \circ \sigma \). Hence by differentiation we obtain

\[
dF_\sigma \circ T(\zeta_\rho) = d(\mathcal{R} \circ \sigma).
\]

It now follows by [5,3] - [5,5] that, for all \( u \in G_A \) and \( X \in \mathfrak{m} \),

\[
\rho_A(u)h = p_{\rho_A(u)\mathcal{H}_B}(d(\mathcal{R} \circ \sigma)(X)) \in \mathcal{H}_A.
\]

Now pick any \( [(u, X)] \in G_A \times G_B \mathfrak{m} = T(G_A / G_B) \) and set \( u(t) := u \exp_{G_A}(tX) \), for all \( t \in \mathbb{R} \). Then

\[
d(\mathcal{R} \circ \sigma)(X) = \left. \frac{d}{dt} \right|_{t=0} \mathcal{R}(\sigma(u(t))) = \rho_A(u)(d\rho_A(X)\phi(u) + d\phi(u, X)).
\]
and therefore, by using \(5.6\), we obtain
\[
\begin{align*}
    h &= \rho_A(u)^{-1}p_{\rho_A(u)H_B}\rho_A(u)(d\rho_A(X)\phi(u) + d\phi(u, X)) \\
    &= p_{H_B}(d\rho_A(X)\phi(u) + d\phi(u, X)) \\
    &= d\phi(u, X) + p_{H_B}(d\rho_A(X)\phi(u))
\end{align*}
\]

since \(\phi: G_A \to H_B\). We also used the fact that \(p_{\rho_A(u)H_B} = \rho_A(u)p_{H_B}\rho_A(u)^{-1}\) for all \(u \in G_A\), since \(\rho_A\) is a unitary representation. Then, because of the way \(h \in H_B\) was chosen, we have \((\nabla\sigma)([(u, X)]) = [(u, d\phi(u, X) + p_{H_B}(d\rho_A(X)\phi(u)))]\), as asserted. \(\square\)

**Remark 5.7.** Since the tautological bundle \(\Pi_{H, S_0}: T_{S_0}(H) \to Gr_{S_0}(H)\) is diffeomorphic to its homogeneous version \(U(H) \times U(p_{S_0})S_0 \to U(H)/U(p_{S_0})\), the two expressions of the covariant derivative, associated with the natural connection on \(\Pi_{H, S_0}\), given in Proposition 2.13 and Proposition 5.6 must coincide.

In fact, using the notations of those propositions and identifying \(uS_0 = uU(p_{S_0})\) we have that \(F_{\sigma}(uS_0) \equiv u\phi(uS_0)\), where we are considering \(\phi: U(H)/U(p_{S_0}) \to S_0\) rather than its \(U(p_{S_0})\)-equivariant version from \(U(H)\) into \(S_0\). Then, for \(X = uY \equiv [(u, Y)] \in T_{uS_0}(Gr_{S_0}(H))\) with \(Y \in \text{Ker} F_{p_{S_0}}\), by differentiating in \(F_{\sigma}(uS_0) = u\phi(uS_0)\) we obtain \(dF_{\sigma}(X) = u(Y\phi(u) + d\phi(u, Y))\), hence
\[
\begin{align*}
P_{uS_0}(dF_{\sigma}(X)) &= P_{uS_0}(u(Y\phi(u) + d\phi(u, Y))) \\
    &= uP_{S_0}(Y\phi(u) + d\phi(u, Y)) \\
    &\equiv [(u, P_{S_0}(Y\phi(u) + d\phi(u, Y)))]
\end{align*}
\]

as it was claimed.

5.3. Differential geometric aspects of completely positive mappings. In this final part of the paper we will discuss some geometric interpretations of the completely positive mappings. More specifically, we will take a fresh look at the Stinespring dilations of completely positive maps from the perspective of the reproducing kernels and the corresponding covariant derivatives, as set forth in the preceding sections. To this end, let \(\Psi: A \to B(H_0)\) be a completely positive map with the Stinespring dilation \(\lambda: A \to B(H)\) given by the equation
\[
\Psi(a) = V^*\lambda(a)V \quad (a \in A),
\]
and satisfying the minimality condition \(H = \text{span}(\lambda(A)H_0)\), where \(V: H_0 \to H\) is an isometry.

First of all, it is clear that setting \(K^\Psi(s, t) := \Psi(s^{-1}t)\) and \(K^\lambda(s, t) := \lambda(s^{-1}t)\), for all \(s, t \in U_A\), we get \(K^\Psi\) and \(K^\lambda\) two reproducing kernels for the trivial vector bundles \(U_A \times H_0 \to U_A\) and \(U_A \times H \to U_A\), respectively. Moreover, the mapping \(\Theta_V = (\text{id}_{U_A} \times V, \text{id}_{U_A})\) is a morphism between the two preceding vector bundles, for which the equality \(\Psi(a) = V^*\lambda(a)V\ (a \in A)\) is equivalent to the fact that \(K^\Psi\) is the pullback kernel of \(K^\lambda\) through \(\Theta_V\). That is,
\[
\Theta_V^{-1}K^\lambda = K^\Psi.
\]

As regards classifying morphisms, first recall that \(V^*V = \text{id}_H, \ VV^* = P_{V(H_0)}\). Put \(S_0 := V(H_0)\). Then the natural kernel, associated with \(\lambda\), for the bundle \(U_A \times S_0 \to U_A\), is
\[
K^\lambda(s, t) := P_{S_0}\lambda(s^{-1}t)_{|S_0} \quad (s, t \in U_A).
\]
Incidentally, note that the equality (5.7) can be written alternatively as
\[ \Psi(a) = V^*P_{S_0} \lambda(a)V \quad (a \in A), \]
since
\[ \Psi(a) = V^*\lambda(a)V = (V^*V)^* \lambda(a)V(V^*V) = V^*P_{S_0} \lambda(a)V \]
for \( a \in A \). Let \( \xi = (s, h) \) be in the fiber \( \{s\} \times S_0 \). Then for all \( t \in U_A \),
\[ (K^\lambda_0)_{\xi}(t) = K^\lambda_0(t, s, h) \equiv (P_{S_0} \lambda(t^{-1}s))_{S_0}(s, h) = P_{S_0} \lambda(t^{-1}) \lambda(s)h \]
whence it follows that \( (K^\lambda_0)_{\xi} \) can be identified with \( \lambda(s)h \) as the function acting on \( t \) as above. Thus the classifying morphism \( \Delta_\lambda \) for the kernel \( K^\lambda_0 \)
is
\[ (s, h) \in U_A \times S_0 \xrightarrow{\delta_\lambda} (\lambda(s)S_0, \lambda(s)h) \in T_{S_0}(H) \]
and the universal theorem tells us that, for \( s \in U_A \), one obtains that \( \Delta_\lambda^*Q_{H, S_0} = K^\lambda_0 \), as it had to be from the universal theorem for kernels.

Thus the classifying morphism \( \Delta_\Psi \) for \( K^\Psi \) is
\[ U_A \times H_0 \xrightarrow{id_{U_A} \times V} U_A \times S_0 \xrightarrow{\delta_\lambda} T_{S_0}(H) \]
and the universal theorem tells us that, for \( s, t \in U_A \),
\[ \Psi(s^{-1}t) = K^\Psi(s, t) = \Delta_\Psi^*Q_{H, S_0}(s, t) = (\Delta_\lambda \Theta_V)^*Q_{H, S_0}(s, t) \]
\[ = \Theta_V^*\Delta_\lambda^*Q_{H, S_0}(s, t) = \Theta_V^*K^\lambda_0(s, t) = V^*P_{S_0} \lambda(s^{-1}t)V. \]

On the other hand \( A = \text{span } U_A \), hence the latter equality is equivalent to (5.8). In other words, the Stinespring dilation theorem, summarized in the formula (5.7), can be regarded as an instance of the universality theorem for reproducing kernels of vector bundles, in the sense of [BG11].

We have shown that a completely positive map \( \Psi \) can be viewed as a reproducing kernel, under the form \( (s, t) \mapsto \Psi(s^{-1}t) \). Let us compute the connection and covariant derivative associated with the above interpretation.

For \( f \in H_0, a \in u_A \) and \( S_0 = V(\mathcal{H}_0), \)
\[ E_{P_{S_0}}(d\lambda(a))Vf = E_{P_{S_0}}(\lambda(a)Vf = p_{S_0}(\lambda(a)Vf) = VV^*\lambda(a)Vf = V\Psi(a)f. \]

Then, using the classifying quasimorphism \( \Delta_\Psi \) and the corresponding pull-back operation for connections, we have that the natural connection on the bundle \( U_A \times H_0 \to U_A \) for the kernel \( \Psi \) is obtained as the composition
\[ ((s, a), (f, h)) \mapsto (\lambda(s), d\lambda(a), (Vf, Vh)) \]
\[ \mapsto ((\lambda(s), 0), (Vf, Vh + E_{P_{S_0}}(d\lambda(a)Vf)) \]
\[ = ((\lambda(s), 0), (Vf, Vh + V\Psi(a)f)) \mapsto ((s, 0), (f, h + \Psi(a)f)). \]

for every \( s \in U_A, a \in u_A, f, h \in H_0 \). In other words, the completely positive map \( \Psi \) can be regarded as a connection \( \Phi_\Psi \) on the trivial bundle in the form of the correspondence \( \Phi_\Psi : (f, h) \mapsto h + \Psi(a)f. \)
To compute the covariant derivative $\nabla_{\Psi}$ of the connection $\Phi$, note that there exists a surjective isometry $\iota_{\lambda}: H \to H^{K_0}$ defined by $\iota_{\lambda}(h) = P_{S_0}(\lambda(\cdot)^{-1}h)$. Then, using an argument similar to that of Propositions 5.5 and 5.6, we find that the covariant derivative associated to the kernel $K_0^\lambda$ is given by

$$\nabla_{\lambda} \sigma_0(u, a) = d\sigma_0(u, a) + P_{S_0}(\lambda(a)\sigma_0(u))$$

for all $u \in U_A$, $a \in u_A$ and every section $\sigma_0: U_A \to S_0$ of the bundle $U_A \times S_0 \to U_A$.

Take now any section $\sigma: U_A \to H_0$ of the bundle $U_A \times H_0 \to U_A$ and put $\sigma_0 := V\sigma: U_A \to S_0$. Since $d\sigma_0 = Vd\sigma$ and $P_{S_0} = VV^*$, by using Corollary A.8 we obtain for $u \in U_A$ and $a \in u_A$, that

$$\nabla_{\Psi}(\sigma_0(u, a)) = d\sigma_0(u, a) + \Psi(a)\sigma_0(u).$$

The completely positive map $\Psi$ can thus be interpreted in terms of covariant derivatives.

**Appendix A. On linear connections and their pull-backs**

For the reader’s convenience, we record here some general facts on connections on Banach fiber bundles that are needed in the present paper. We use [KM97] and [La01] as the main references, but we will also provide proofs for some results where we were unable to find convenient references in the literature.

**A.1. Connections on fiber bundles.**

**Definition A.1.** Let $\varphi: M \to Z$ a fiber bundle and consider both vector bundle structures of the tangent space $TM$:

- $\tau_M: TM \to M$, the tangent bundle of the total space $M$.
- $T\varphi: TM \to TZ$, the tangent map of $\varphi$.

A connection on the bundle $\varphi: M \to Z$ is a smooth map $\Phi: TM \to TM$ with the following properties:

(i) $\Phi \circ \Phi = \Phi$;

(ii) the pair $(\Phi, \text{id}_M)$ is an endomorphism of the bundle $\tau_M: TM \to M$;

(iii) for every $x \in M$, if we denote $\Phi_x := \Phi|_{T_xM}: T_xM \to T_xM$, then we have $\text{Ran}(\Phi_x) = \text{Ker}(T_x\varphi)$, so that we get an exact sequence

$$0 \to H_xM \hookrightarrow T_xM \overset{\Phi_x}{\to} T_xM \overset{T_x\varphi}{\to} T_{\varphi(x)}Z \to 0.$$  

Here $H_xM := \text{Ker}(\Phi_x)$ is a closed linear subspace of $T_xM$ called the space of horizontal vectors at $x \in M$. Similarly, the space of vertical vectors at $x \in M$ is $V_xM := \text{Ker}(T_x\varphi)$. Then we have the direct sum decomposition $T_xM = H_xM \oplus V_xM$, for every $x \in M$ (cf. [KM97, subsect. 37.2]).

We consider in this paper two special types of connections.

1. If $\varphi: M \to Z$ is a principal bundle with structure group $G$ acting to the right on $M$ by

$$(x, g) \mapsto \mu_g(x) = \mu(x, g), \quad M \times G \to M$$

then a connection $\Phi$ on $\varphi: M \to Z$ is called principal whenever it is $G$-equivariant, that is,

$$T(\mu_g) \circ \Phi = \Phi \circ T(\mu_g)$$

for all $g \in G$ (cf. [KM97, subsect. 37.19]).
(2) If \( \varphi: M \to Z \) is a vector bundle then a connection \( \Phi \) on \( \varphi: M \to Z \) is called linear if the pair \((\Phi, \id_{TZ})\) is an endomorphism of the vector bundle \( T\varphi: TM \to TZ \) (i.e., if \( \Phi \) is linear on the fibers of the bundle \( T\varphi \)); see [KM97, subsect. 37.27].

We are interested in particular in vector bundles constructed out of principal ones. Recall how they appear: Let \( \pi \): \( \mathcal{P} \to Z \) be a principal Banach bundle with the structure Banach-Lie group \( G \) and the action \( \mu: \mathcal{P} \times G \to \mathcal{P} \). Assume that \( \rho: G \to \mathcal{B}(E) \) is a smooth representation of \( G \) by linear operators on a Banach space \( E \), and denote by

\[
[(p,e)] \mapsto \pi(p), \quad \Pi: D = \mathcal{P} \times_G E \to Z
\]

de the associated vector bundle (see [Bose 67, subsect. 6.5] and [KM97, subsect. 37.12]). Here \( \mathcal{P} \times_G E \) denotes the quotient of \( \mathcal{P} \times E \) with respect to the equivalence relation defined by

\[
(\forall g \in G) \quad (p,e) \sim (\mu(p,g), \rho(g^{-1})e) =: \bar{\mu}(g)(p,e)
\]

whenever \((p,e) \in \mathcal{P} \times E\), and we denote by \([(p,e)]\) the equivalence class of any pair \((p,e)\).

In this way, \( \Pi: \mathcal{P} \times_G E \to Z \) is a vector \( G \)-bundle.

**Remark A.2.** Every connection on a principal bundle \( \pi \) induces a linear connection on any vector bundle associated to \( \pi \). A good reference for that induction procedure in infinite dimensions is [KM97]. We will recall here the corresponding construction since we will need it in order to describe specific induced connections later on (see for instance the comment prior to Theorem 22.2 below).

For a Banach-Lie group \( G \) with the Lie algebra \( \mathfrak{g} = T_1G \) let \( \lambda_\mathfrak{g}: G \to G, \lambda_\mathfrak{g}(h) = gh \) for all \( g, h \in G \). Then the mapping \((g,X) \mapsto T_1(\lambda_\mathfrak{g})X\) is a diffeomorphism \( G \times g \to TG \), and thus the tangent manifold \( TG \) is endowed with structure of a semidirect product of groups \( TG \equiv G \ltimes \Lambda_{Ad_G} \mathfrak{g} \), defined by the adjoint action of \( G \) on \( \mathfrak{g} \); see [KM97, Cor. 38.10]. The multiplication in the group \( TG \) is given by

\[
(g_1,X_1)(g_2,X_2) = (g_1g_2, Ad_G(g_2^{-1})X_1 + X_2), \quad (g_1,g_2 \in G; X_1, X_2 \in \mathfrak{g}).
\]

Let \( \pi: \mathcal{P} \to Z \) be a principal bundle with the structure group \( G \) acting to the right by \( \mu: \mathcal{P} \times G \to \mathcal{P} \). If \( \rho: G \to \mathcal{B}(E) \) is a smooth representation as above, then we can form the associated vector bundle \( \Pi: D = \mathcal{P} \times_G E \to Z \).

For describing a connection induced on \( \Pi \), one needs a specific description of the tangent space of the total space \( \mathcal{P} \times_G E \), and to this end one uses the fact that the tangent functor commutes with the construction of associated bundles. In fact, the tangent bundle \( T\pi: T\mathcal{P} \to TZ \) is a principal bundle with the structure group \( TG = G \ltimes \Lambda_{Ad_G} \mathfrak{g} \) and right action \( T\mu: T\mathcal{P} \times TG \to T\mathcal{P} \) ([KM97, Th. 37.18(1)]). The representation \( \rho \) gives a linear action \( G \times E \to E \), and by computing the tangent map of that action it follows that the tangent map of the above representation can be viewed as the smooth representation \( T\rho: G \ltimes \Lambda_{Ad_G} \mathfrak{g} \to \mathcal{B}(E \oplus E) \), which is easily computed as

\[
(g,X) \mapsto \begin{pmatrix} \rho(g) & 0 \\ 0 & \rho(g) \end{pmatrix} \begin{pmatrix} 1 & 0 \\ d\rho(X) & 1 \end{pmatrix} = \begin{pmatrix} \rho(g) & 0 \\ \rho(g)d\rho(X) & \rho(g) \end{pmatrix},
\]

where the resulting matrix is to be understood as acting on vectors of \( E \oplus E \) written in column form. Using the representation \( T\rho \), the tangent bundle of the vector bundle \( \Pi: D = \mathcal{P} \times_G E \to Z \) can be described as the vector bundle

\[
\tau_D: TD = T\mathcal{P} \times_{G \ltimes \Lambda_{Ad_G} \mathfrak{g}} (E \oplus E) \to \mathcal{P} \times_G E = D,
\]
which is associated to the principal bundle $T\pi: TP \to TZ$ and is defined by
\[ \tau_D: [(v_p, (f, h))] \mapsto [p, f] \quad (v_p \in T_p P; f, h \in E) \]
([KM97, Th. 37.18(4)]).

If now $\Phi: TP \to TP$ is a principal connection on the principal bundle $\pi: P \to Z$, then the mapping $\Phi \times \text{id}_{TE}: TP \times TE \to TP \times TE$ is $T\Phi$-equivariant and factorizes through a map $\bar{\Phi}: T(P \times_G E) \to T(P \times_G E) = TP \times_{TG} TE$. That is, there exists the commutative diagram
\[
\begin{array}{ccc}
TP \times TE & \xrightarrow{\Phi \times \text{id}_{TE}} & TP \times TE \\
\downarrow & & \downarrow \\
TP \times_{TG} TE & \xrightarrow{\bar{\Phi}} & TP \times_{TG} TE
\end{array}
\]
and $\bar{\Phi}$ is the connection induced by $\Phi$ on $T(P \times_G E)$; see [KM97] subsect. 37.24.

We now briefly recall the covariant derivatives (as in [Vi67]) and we then provide a proposition needed in the specific computations carried out in the present paper.

Let $\Pi: D \to Z$ be a vector bundle with a linear connection $\Phi: TD \to TD$. Let $VD = \ker(T\Pi) (\subseteq TD)$ be the vertical part of the tangent bundle $\tau_D: TD \to D$. A useful description of $VD$ can be obtained by considering the fibered product $D \times D := \{(x_1, x_2) \in D \times D \mid \Pi(x_1) = \Pi(x_2)\}$ along with the natural maps $r_j: D \times D \to D, \ r_j(x_1, x_2) = x_j$ for $j = 1, 2$. Define for every $(x_1, x_2) \in D \times D$ the path $c_{x_1, x_2}: \mathbb{R} \to D, c_{x_1, x_2}(t) = x_1 + tx_2$. Then it is easily seen that we have a well-defined diffeomorphism $\varepsilon: D \times D \to VD, \ \varepsilon(x_1, x_2) = c_{x_1, x_2}(0) \in T_{x_1}D$, which is in fact an isomorphism between the vector bundles $r_j: D \times D \to D$ and $\tau_D|_{VD}: VD \to D$. We then get a natural mapping $r := r_2 \circ \varepsilon^{-1}: VD \to D$ and the pair $(r, \Pi)$ is a homomorphism of vector bundles from $\tau_D|_{VD}: VD \to D$ to $\Pi: D \to Z$.

Next let $\Omega^1(Z, D)$ the space of locally defined smooth differential 1-forms on $Z$ with values in the bundle $\Pi: D \to Z$, hence the set of smooth mappings $\eta: \tau_Z^{-1}(Z_n) \to D$, where $\tau_Z: TZ \to Z$ is the tangent bundle and $Z_n$ is a suitable open subset of $Z$, such that for every $z \in Z_n$ we have a bounded linear operator $\eta_z := \eta|_{T_zZ}: T_zZ \to D_z = \Pi^{-1}(z)$. (So the pair $(\eta, \text{id}_{Z})$ is a homomorphism of vector bundles from the tangent bundle $\tau_D|_{Z_n}$ to the bundle $\Pi$.) For the sake of simplicity we actually omit the subscript $\eta$ in $Z_n$, as if the forms were always defined throughout $Z$; in fact, the algebraic operations are performed on the intersections of the domains, and so on. Similarly, we let $\Omega^0(Z, D)$ be the space of locally defined smooth sections of the vector bundle $\Pi$.

\textbf{Definition A.3.} The \textit{covariant derivative} for the linear connection $\Phi$ is the linear mapping $\nabla: \Omega^0(Z, D) \to \Omega^1(Z, D)$, defined for every $\sigma \in \Omega^0(Z, D)$ by the composition $\nabla \sigma: TZ \xrightarrow{T\sigma} TD \xrightarrow{\Phi} VD \xrightarrow{r} D$ that is, $\nabla \sigma = (r \circ \Phi) \circ T\sigma$. (The composition $r \circ \Phi$ is the so-called \textit{connection map}.)

\textbf{Proposition A.4.} Let $\Pi: D \to Z$ and $\Pi: D \to Z$ be vector bundles endowed with the linear connections $\Phi$ and $\Phi$, with the corresponding covariant derivatives $\nabla$ and $\nabla$, respectively. Assume that $\Theta = (\delta, \zeta)$ is a homomorphism of vector bundles from
\[ \Pi \text{ into } \tilde{\Pi} \text{ such that } T\delta \circ \Phi = \tilde{\Phi} \circ T\delta. \] If \( \sigma \in \Omega^0(Z,D) \) and \( \tilde{\sigma} \in \Omega^0(\tilde{Z},\tilde{D}) \) are such that \( \delta \circ \sigma = \tilde{\sigma} \circ \zeta \), then \( \delta \circ \nabla \sigma = \tilde{\nabla} \sigma \circ T\zeta \).

**Proof.** First let \( r: \mathcal{V}D \to D \) and \( \tilde{r}: \mathcal{V}\tilde{D} \to \tilde{D} \) be the natural mappings and note that
\[ \delta \circ r = \tilde{r} \circ T\delta. \] (A.1)

In order to see why this equality holds true we need the mapping \( \delta \times \delta: D \times D \to \tilde{Z} \times \tilde{Z} \) given by \( (\delta \times \delta)(x_1, x_2) = (\delta(x_1), \delta(x_2)) \), which is well defined since \( \tilde{\Pi} \circ \delta = \zeta \circ \Pi \). Since \( \delta \) is fiberwise linear, it follows that with the notation of Definition A.3 we have \( \delta \circ c_{x_1, x_2} = c_{\delta(x_1), \delta(x_2)}: \mathbb{R} \to \tilde{D} \) for all \( (x_1, x_2) \in D \times D \). By taking the velocity vectors at \( 0 \in \mathbb{R} \) for these paths we get \( T\delta \circ \varepsilon = \tilde{\varepsilon} \circ (\delta \times \delta): D \times D \to T\tilde{D} \). Therefore \( \tilde{\varepsilon}^{-1} \circ T\delta = (\delta \times \delta) \circ \varepsilon^{-1} \) and then, by using the obvious equality
\[ \tilde{\tau}_2 \circ (\delta \times \delta) = \delta \circ r_2: D \times D \to \tilde{D}, \] we get
\[ \tilde{\tau} \circ T\delta = \tilde{\tau}_2 \circ \tilde{\varepsilon}^{-1} \circ T\delta = \tilde{\tau}_2 \circ (\delta \times \delta) \circ \varepsilon^{-1} = \delta \circ r_2 \circ \varepsilon^{-1} = \delta \circ r \]
hence (A.1) holds true.

We now come back to the proof of the assertion. By using (A.1) and the equality \( T\delta \circ \Phi = \tilde{\Phi} \circ T\delta \) we get
\[ \delta \circ (r \circ \Phi) = \tilde{r} \circ T\delta \circ \Phi = (\tilde{r} \circ \tilde{\Phi}) \circ T\delta. \] (A.2)

On the other hand we have \( \delta \circ \sigma = \tilde{\sigma} \circ \zeta \), and therefore \( T\delta \circ T\sigma = T\tilde{\sigma} \circ T\zeta \). We then get
\[ \tilde{\nabla} \tilde{\sigma} \circ T\zeta = (\tilde{r} \circ \tilde{\Phi}) \circ T\tilde{\sigma} \circ T\zeta = (\tilde{r} \circ \tilde{\Phi}) \circ T\delta \circ T\sigma = \delta \circ (r \circ \Phi) \circ T\sigma = \delta \circ \nabla \sigma \]
where the next-to-last equality follows by (A.1), and this completes the proof. \( \square \)

**A.2. Pull-backs of connections.** Pull-backs of connections on various types of finite-dimensional bundles have been studied in several papers; see for instance [NR61], [NR63], [Le68], [Sch80], [PR86]. We now establish a result (Proposition A.6) that belongs to that circle of ideas and is appropriate for the applications we want to make in infinite dimensions. Unlike the descriptions of the pull-backs of connections that we were able to find in the literature, the method provided here is more direct in the sense that it requires neither the connection map, nor any connection forms, nor the covariant derivative, but rather the connection itself. The intertwining property of the covariant derivatives follows at once (Corollary A.8).

We will need the following simple lemma.

**Lemma A.5.** Let \( T: \mathcal{E} \to \tilde{\mathcal{E}} \) be a continuous (conjugate-)linear operator between two Banach spaces \( \mathcal{E} \) and \( \tilde{\mathcal{E}} \). Let us assume that there are two closed linear subspaces \( \mathcal{F} \subset \mathcal{E} \) and \( \tilde{\mathcal{F}} \subset \tilde{\mathcal{E}} \) such that:

(i) the operator \( T \) induces a (conjugate-)linear isomorphism \( T|_{\mathcal{F}}: \mathcal{F} \to \tilde{\mathcal{F}} \);
(ii) \( \text{Ran} \tilde{\mathcal{P}} = \tilde{\mathcal{F}} \), for some projection \( \mathcal{P}: \tilde{\mathcal{E}} \to \tilde{\mathcal{E}} \).

Then there exists a unique projection \( \mathcal{P} \in \text{End}(\mathcal{E}) \) such that \( \text{Ran} \mathcal{P} = \mathcal{F} \) and \( \mathcal{P} \circ T = T \circ \mathcal{P} \).
Proof. Existence: Define

\[ P := (T|_\mathcal{F})^{-1} \circ \bar{P} \circ T \in \text{End} \left( \mathcal{E} \right) \]  
\[ \text{(A.3)} \]

It is clear that Ran \( P = \mathcal{F} \) and moreover \( P|_\mathcal{F} = \text{id}_\mathcal{F} \), hence \( P \circ P = P \). Then the commutativity of the diagram is satisfied by the construction of \( P \).

Uniqueness: Assume that \( P_1 \in \text{End} \left( \mathcal{E} \right) \) is another operator satisfying the properties of the statement. Then for arbitrary \( x \in \mathcal{E} \) we have \( T(P_1 x) = \bar{P} \bar{T} x = T(\bar{P} x) \).

Since \( P_1 x, \bar{P} x \in \mathcal{F} \) and \( T|_\mathcal{F} : \mathcal{F} \to \mathcal{F} \) is an isomorphism, it then follows that \( P_1 x = \bar{P} x \). Thus \( P_1 = P \) and we are done. \( \square \)

Proposition A.6. Let \( \varphi : M \to Z \) and \( \tilde{\varphi} : \tilde{M} \to \tilde{Z} \) be fiber bundles modeled on Banach spaces, and let \( \Theta = (\delta, \zeta) \) be a bundle homomorphism, that is, the diagram

\[ M \xrightarrow{\delta} \tilde{M} \]  
\[ \varphi \downarrow \quad \bar{\zeta} \downarrow \]  
\[ Z \xrightarrow{\zeta} \tilde{Z} \]

is commutative and both \( \delta \) and \( \zeta \) are smooth. In addition, assume that for every \( s \in Z \) the mapping \( \delta \) induces a diffeomorphism of the fiber \( M_s := \varphi^{-1}(\{s\}) \) onto the fiber \( \tilde{M}_{\zeta(s)} := \bar{\varphi}^{-1}(\zeta(s)) \).

Then for every connection \( \tilde{\Phi} \) on the bundle \( \tilde{\varphi} : \tilde{M} \to \tilde{Z} \) there exists a unique connection \( \Phi \) on the bundle \( \varphi : M \to Z \) such that the diagram

\[ TM \xrightarrow{T\delta} T\tilde{M} \]  
\[ \Phi \downarrow \quad \bar{\Phi} \downarrow \]  
\[ TM \xrightarrow{T\delta} T\tilde{M} \]

is commutative.

Moreover, if both \( \varphi : M \to Z \) and \( \tilde{\varphi} : \tilde{M} \to \tilde{Z} \) are principal (vector) bundles, the pair \( \Theta = (\delta, \zeta) \) is a homomorphism of principal bundles (or of vector bundles, and in this case \( \delta \) can be linear) bundles, and \( \Phi \) is a principal (linear or conjugate-linear) connection, then so is \( \Phi \).

Proof. We have for every \( x \in M \) the continuous operator \( T_x \delta : T_x M \to T_{\delta(x)} \tilde{M} \) (which is either linear or conjugate-linear), and also the relations \( T_x (\mathcal{M}_\varphi(x)) = \mathcal{V}_x \to T_x M \) and

\[ T_{\delta(x)} (\tilde{M}_{\zeta(\varphi(x))}) = T_{\delta(x)} (\tilde{M}_{\tilde{\varphi}(\delta(x))}) = \mathcal{V}_{\delta(x)} \tilde{M} \to T_{\delta(x)} \tilde{M}. \]

Since \( \delta|_{\mathcal{M}_\varphi(x)} : \mathcal{M}_\varphi(x) \to \tilde{M}_{\zeta(\mathcal{M}_\varphi(x))} \) is a diffeomorphism by hypothesis, it thus follows that the operator \( T_x \delta \) induces a (conjugate-)linear isomorphism \( \mathcal{V}_x M \to \mathcal{V}_{\delta(x)} \tilde{M} \). Now Lemma A.3 shows that there exists a unique idempotent operator \( \Phi_x : T_x M \to T_x M \) such that \( \text{Ran} \Phi_x = \mathcal{V}_x M \) and \( (T_x \delta) \circ \Phi_x = \Phi_{\delta(x)} \circ (T_x \delta) \). In fact it is defined by

\[ \Phi_x := (T_x \delta|_{\mathcal{V}_x M})^{-1} \circ \Phi_{\delta(x)} \circ T_x \delta \quad (x \in M). \]

If we put together the operators \( \Phi_x \) with \( x \in M \), we get the map \( \Phi : TM \to TM \) we were looking for. What still remains to be done is to check that \( \Phi \) is smooth. Since this is a local property, we may assume that both bundles \( \mathcal{I} \) and \( \tilde{\mathcal{I}} \) are trivial. Let \( S \) and \( \tilde{S} \) be their typical fibers, respectively. Then \( M = Z \times S \) and \( \tilde{M} = \tilde{Z} \times \tilde{S} \),
hence $TM = TM \times TS$ and $\tilde{M} = T\tilde{Z} \times T\tilde{S}$. The fact that $\tilde{\Phi}$ is a connection means that for every $(\tilde{z}, \tilde{k}) \in \tilde{Z} \times \tilde{S}$ we have an idempotent operator $\tilde{\Phi}_{(\tilde{z}, \tilde{k})}$ on $T\tilde{z}\tilde{Z} \times T\tilde{k}\tilde{S}$ with $\text{Ran} \tilde{\Phi}_{(\tilde{z}, \tilde{k})} = \{0\} \times T\tilde{k}\tilde{S}$.

Moreover, we have the smooth map $\delta: Z \times S \to \tilde{Z} \times \tilde{S}$ for which there exists a smooth map $d: Z \times S \to \tilde{S}$ such that $\delta(\tilde{z}, k) = (\zeta(z), d(z, k))$ for all $z \in Z$ and $k \in S$. The hypothesis that $\delta$ is a fiberwise diffeomorphism is equivalent to the fact that for every $z \in Z$ we have the diffeomorphism $d(z, \cdot): S \to \tilde{S}$. It follows by $[A.3]$ that, for arbitrary $(z, k) \in Z \times S$,

$$\Phi_{(z, k)} = T_k(d(z, \cdot))^{-1} \circ \tilde{\Phi}_{\delta(z, k)} \circ T_{(z, k)} \delta \in \text{End} (T_zZ \times T_kS)$$

which clearly shows that $\Phi: TZ \times TS \to TZ \times TS$ is smooth. (Note that the smoothness of the mapping $(z, k) \mapsto T_k(d(z, \cdot))^{-1}$ is ensured by the fact that we are working with Banach manifolds.)

The remainder of the proof is straightforward.

**Definition A.7.** In the setting of Proposition $[A.6]$ we say that the connection $\Phi$ is the **pull-back of the connection** $\tilde{\Phi}$ and we denote $\Phi = \Theta^*(\tilde{\Phi})$.

**Corollary A.8.** Let $\Pi: D \to Z$ and $\tilde{\Pi}: \tilde{D} \to \tilde{Z}$ be vector bundles. Assume that $\Theta = (\delta, \zeta)$ is a homomorphism of vector bundles from $\Pi$ into $\tilde{\Pi}$ such that for every $s \in Z$ the mapping $\delta$ induces an isomorphism of the fiber $D_s := \Pi^{-1}(\{s\})$ onto the fiber $\tilde{D}_{\zeta(s)} := \tilde{\Pi}^{-1}(\zeta(s))$. Consider any linear connection $\tilde{\Phi}$ on the vector bundle $\tilde{\Pi}$ and its pull-back $\Phi = \Theta^*(\tilde{\Phi})$ on the vector bundle $\Pi$, with the corresponding covariant derivatives $\nabla$ and $\tilde{\nabla}$, respectively. If we have $\sigma \in \Omega^0(Z, D)$ and $\tilde{\sigma} \in \Omega^0(\tilde{Z}, \tilde{D})$ such that $\delta \circ \sigma = \tilde{\sigma} \circ \zeta$, then $\delta \circ \nabla \sigma = \tilde{\nabla} \tilde{\sigma} \circ T\zeta$.

**Proof.** Use Propositions $[A.6]$ and $[A.3]$.

**Acknowledgment.** We wish to thank Professor Joachim Hilgert for kindly sending over one of his papers upon our request, and Professor Radu Pantilie for pointing out useful references and facts on linear connections.
