Stopping Sets of Algebraic Geometry Codes

Jun Zhang, Fang-Wei Fu and Daqing Wan

Abstract

Stopping sets and stopping set distribution of a linear code play an important role in the performance analysis of iterative decoding for this linear code. Let $C$ be an $[n, k]$ linear code over $\mathbb{F}_q$ with parity-check matrix $H$, where the rows of $H$ may be dependent. Let $[n] = \{1, 2, \ldots, n\}$ denote the set of column indices of $H$. A stopping set $S$ of $C$ with parity-check matrix $H$ is a subset of $[n]$ such that the restriction of $H$ to $S$ does not contain a row of weight 1. The stopping set distribution $\{T_i(H)\}_{i=0}^{n}$ enumerates the number of stopping sets with size $i$ of $C$ with parity-check matrix $H$. Denote $H^*$ the parity-check matrix consisting of all the non-zero codewords in the dual code $C^\perp$. In this paper, we study stopping sets and stopping set distributions of some residue algebraic geometry (AG) codes with parity-check matrix $H^*$. First, we give two descriptions of stopping sets of residue AG codes. For the simplest AG codes, i.e., the generalized Reed-Solomon codes, it is easy to determine all the stopping sets. Then we consider AG codes from elliptic curves. We use the group structure of rational points of elliptic curves to present a complete characterization of stopping sets. Then the stopping sets, the stopping set distribution and the stopping distance of the AG code from an elliptic curve are reduced to the search, counting and decision versions of the subset sum problem in the group of rational points of the elliptic curve, respectively. Finally, for some special cases, we determine the stopping set distributions of AG codes from elliptic curves.

Stopping sets, stopping set distribution, stopping distance, algebraic geometry codes, elliptic curves, subset sum problem.

I. INTRODUCTION

Let $C$ be an $[n, k, d]$ linear code over $\mathbb{F}_q$ with length $n$, dimension $k$ and minimum distance $d$. Let $H$ be a parity-check matrix of $C$, where the rows of $H$ may be dependent. Let $[n] = \{1, 2, \ldots, n\}$ denote the set of column indices of $H$. A stopping set $S$ of $C$ with parity-check matrix $H$ is a subset of $[n]$ such that the restriction of $H$ to $S$, say $H(S)$, does not contain a row of weight 1. The stopping set distribution $\{T_i(H)\}_{i=0}^{n}$ enumerates the number of stopping sets with size $i$ of $C$ with parity-check matrix $H$. Note that the empty set $\emptyset$ is defined as a stopping set and $T_0(H) = 1$. A number of researchers have recently studied the stopping sets and stopping set distributions of linear codes, e.g., see [1, 2, 5–18, 20, 21, 24–26, 28, 32–36]. Stopping sets and stopping set distribution of a linear code are used to determine the performance of this linear code under iterative decoding [5].

The stopping distance \( s(H) \) of \( C \) with the parity-check matrix \( H \) is the minimum size of nonempty stopping sets. It plays an important role in the performance analysis of the iterative decoding, just as the role of the minimum Hamming distance \( d \) of a code for maximum-likelihood or algebraic decoding. Analogously to the redundancy of a linear code, Schwartz and Vardy [28] introduced the stopping redundancy \( \rho(C) \), the minimal number of rows in the parity-check matrix \( H \) for the linear code \( C \) such that the stopping distance \( s(H) = d \), to characterize the minimal “complexity” of the iterative decoding for the code \( C \). The stopping redundancy of some linear codes such as Reed-Muller codes, cyclic codes and maximal distance separable (MDS) codes have been studied recently [8, 11–13, 28].

Note that the stopping distance, the stopping sets and stopping set distribution depend on the choice of the parity-check matrix \( H \) of \( C \). Recall that \( H^* \) is the parity-check matrix consisting of all non-zero codewords in the dual code \( C^\perp \). For any parity-check matrix \( H \), it is obvious that \( T_i(H) \geq T_i(H^*) \) for all \( i \), since \( H \) is a sub-matrix formed by some rows of \( H^* \). Although the iterative decoding with the parity-check matrix \( H^* \) has the highest decoding complexity, it achieves the best possible performance as it has the smallest stopping set distribution. It is known from [34] and [16] that the iterative decoding with the parity-check matrix \( H^* \) is an optimal decoding for the binary erasure channel. The stopping set distribution is used to characterize the performance under iterative decoding. So it is important to determine the stopping set distribution of \( C \) with the parity-check matrix \( H^* \). However, in general, it is difficult to determine the stopping set distribution of \( C \) with the parity-check matrix \( H^* \). Using finite geometry, Jiang et al. [17] gave characterizations of stopping sets of some Reed-Muller codes (the Simplex codes, the Hamming codes, the first order Reed-Muller codes and the extended Hamming codes). And they determined the stopping set distributions of these codes. Since the iterative decoding with parity-check matrix \( H^* \) has the highest decoding complexity, they [17] considered a parity-check matrix \( H \), a submatrix of \( H^* \), such that the stopping set distribution of \( C \) with parity-check matrix \( H \) is the same as that with \( H^* \), but has the smallest number of rows. Such a parity-check matrix \( H \) is called optimal in certain sense. In general, it is difficult to obtain an optimal parity-check matrix for a general linear code. In [17], they obtained optimal parity-check matrices for the Simplex codes, the Hamming codes, the first order Reed-Muller codes and the extended Hamming codes. They also proposed an interesting problem to determine the stopping set distributions of well known linear codes with the parity-check matrix \( H^* \). In this paper, we consider AG codes and a specific class of AG codes, i.e., AG codes associated with elliptic curves.

From now on, we always choose the parity-check matrix \( H^* \) for linear codes in this paper. It is well-known that

\[ s(H^*) = d(C). \]
Note that the generalized Reed-Solomon codes are MDS codes. For the \([n, k, d]\) MDS code \(C\), i.e., \(d = n - k + 1\), its dual code \(C^\perp\) is still an \([n, n - k, k + 1]\) MDS code. Since any non-zero codeword in \(C^\perp\) has at most \(n - k - 1\) zeros and any \((n - k)\) positions form an information set, we have

**Proposition 2.** Let \(C\) be an \([n, k, n - k + 1]\) MDS code. Then

(i) any subset of \([n]\) with cardinality \(\geq n - k + 1\) is a stopping set;

(ii) any non-empty subset of \([n]\) with cardinality \(\leq n - k\) is not a stopping set.

By Proposition 2, we obtain the stopping set distribution of MDS codes.

**Corollary 3.** Let \(C\) be an \([n, k, n - k + 1]\) MDS code. Then the stopping set distribution of \(C\) is given by

\[
T_i(H^*) = \begin{cases} 
1, & \text{if } i = 0, \\
0, & \text{if } 1 \leq i \leq n - k, \\
\binom{n}{i}, & \text{if } i \geq n - k + 1. 
\end{cases}
\]

As a generalization of the generalized Reed-Solomon codes, next we study the stopping sets and stopping set distributions of AG codes.

**Constructions of AG codes.**

Without more special instructions, we fix some notation valid for the entire paper.

- \(X/\mathbb{F}_q\) is a geometrically irreducible smooth projective curve of genus \(g\) over the finite field \(\mathbb{F}_q\) with function field \(\mathbb{F}_q(X)\).

- \(X(\mathbb{F}_q)\) is the set of all \(\mathbb{F}_q\)-rational points on \(X\).

- \(D = \{P_1, P_2, \cdots, P_n\}\) is a proper subset of \(X(\mathbb{F}_q)\).

- Without any confusion, also write \(D = P_1 + P_2 + \cdots + P_n\).

- \(G\) is a divisor of degree \(m\) (\(2g - 2 < m < n\)) with \(\text{Supp}(G) \cap D = \emptyset\).

Let \(V\) be a divisor on \(X\). Denote by \(\mathcal{L}(V)\) the \(\mathbb{F}_q\)-vector space of all rational functions \(f \in \mathbb{F}_q(X)\) with the principal divisor \(\text{div}(f) \geq -V\), together with the zero function. And Denote by \(\Omega(V)\) the \(\mathbb{F}_q\)-vector space of all the Weil differentials \(\omega\) with divisor \(\text{div}(\omega) \geq V\), together with the zero differential (cf. [31]). For any \(\mathbb{F}_q\)-rational point \(P\) on \(X\), choose one uniformizer \(t\) for \(P\). Then for any differential \(\omega\), we can write \(\omega = u dt\) with some \(u \in \mathbb{F}_q(X)\). Write the \(P\)-adic expansion \(u = \sum_{i = i_0}^{\infty} a_i t^i\) for some \(i_0 \in \mathbb{Z}\) and \(a_i \in \mathbb{F}_q\), the residue map of \(\omega\) at the point \(P\) is defined to be

\[
\text{res}_P(\omega) = \text{res}_{P_i}(u) = a_{-1}.
\]

One can show that the above definition is well-defined [31, Proposition 4.2.9].

The residue AG code \(C_\Omega(D, G)\) is defined to be the image of the following residue map:

\[
\text{res} : \Omega(G - D) \rightarrow \mathbb{F}_q^n \\
\omega \mapsto (\text{res}_{P_1}(\omega), \text{res}_{P_2}(\omega), \cdots, \text{res}_{P_n}(\omega)).
\]
And its dual code, the functional AG code $C_{\mathcal{L}}(D, G)$ is defined to be the image of the following evaluation map:

$$
ev: \mathcal{L}(G) \to \mathbb{F}_q^n; 
\ f \mapsto (f(P_1), f(P_2), \cdots, f(P_n)) \ .$$

They are linear codes over $\mathbb{F}_q$, and have the code parameters $[n, n - m + g - 1, d \geq m - 2g + 2]$ and $[n, m - g + 1, d \geq n - m]$, respectively. And they can be represented from each other [31, Proposition 8.1.2].

For the simplest AG codes, i.e., the generalized Reed-Solomon codes, we have determined all the stopping sets. Then we consider the AG codes $C_{\Omega}(D, G)$ from elliptic curves. In this case, using the Riemann-Roch theorem, the stopping sets can be characterized completely as follows.

**Main Theorem.** Let $E$ be an elliptic curve over $\mathbb{F}_q$, $D = \{P_1, P_2, \cdots, P_n\}$ a subset of $E(\mathbb{F}_q)$ such that the zero element $O \notin D$ and let $G = mO$ ($0 < m < n$). The non-empty stopping sets of the residue code $C_{\Omega}(D, G)$ are given as follows:

(i) Any non-empty subset of $[n]$ with cardinality $\leq m - 1$ is not a stopping set.
(ii) Any subset of $[n]$ with cardinality $\geq m + 2$ is a stopping set.
(iii) $A \subseteq [n], \#A = m + 1$, is a stopping set if and only if for all $i \in A$, the sum

$$\sum_{j \in A \setminus \{i\}} P_j \neq O \ .$$

(iv) $A \subseteq [n], \#A = m$, is a stopping set if and only if

$$\sum_{j \in A} P_j = O \ .$$

(v) Denote by $S(m)$ and $S(m + 1)$ the two sets of stopping sets with cardinality $m$ and $m + 1$ in the cases (iv) and (iii), respectively. Let

$$S^+(m) = \bigcup_{A \in S(m)} \{A \cup \{i\} : i \in [n] \setminus A\} \ .$$

Then the union in $S^+(m)$ is a disjoint union, and we have

$$S(m + 1) \cap S^+(m) = \emptyset \ ,$$

and

$$S(m + 1) = \{\text{all subsets of } [n] \text{ with cardinality } m + 1 \} \setminus S^+(m) \ .$$

The proof will be given in Section 3. By this theorem, the stopping set distribution of $C_{\Omega}(D, G)$ follows immediately.

**Theorem 4.** Notation as above. The stopping set distribution of $C_{\Omega}(D, G)$ with the parity-check matrix
Then by Theorem 4, we easily see that the stopping distance of $C_{E}(D, G)$ is $m$ or $m + 1$. But to decide it is equivalent to a decision version of $m$-subset sum problem [19, 22, 23] in the group $E(\mathbb{F}_{q})$, which is an $\text{NP}$-hard problem under $\text{RP}$-reduction [3]. Hence to compute the stopping distance of $C_{E}(D, G)$ is $\text{NP}$-hard under $\text{RP}$-reduction. To compute the stopping set distribution is a counting version of $m$-subset sum problem in the group $E(\mathbb{F}_{q})$, so it is also an $\text{NP}$-hard problem. But for a special $D \subseteq E(\mathbb{F}_{q})$ with strong algebraic structure, it is possible to compute the complete stopping set distribution. For instance, if we take $D = P \setminus \{O\}$, where $P$ is a subgroup of $E(\mathbb{F}_{q})$. In particular, in application we always choose $D = E(\mathbb{F}_{q}) \setminus \{O\}$ to get a long linear code which is called standard elliptic code. Denote $N = |P|$ the cardinality of $P$, $\exp(P)$ the exponent of $P$, $P[d]$ the $d$-torsion subgroup of $P$, and

$$N(m) = \frac{1}{N} \sum_{s \mid \exp(P)} (-1)^{m + \left[\frac{m}{s}\right]} \binom{N/s - 1}{m/s} \sum_{d \mid s} \mu(s/d) \#P[d],$$

respectively. It is known from [19, 23] that $\#S(m) = N(m)$. Hence, we have

**Theorem 5.** Let $D = P \setminus \{O\}$, where $P$ is a subgroup of $E(\mathbb{F}_{q})$. The stopping set distribution of $C_{E}(D, G)$ with the parity-check matrix $H^*$ is

$$T_{i}(H^*) = \begin{cases} 1, & \text{if } i = 0, \\ 0, & \text{if } 1 \leq i \leq m - 1, \\ \#S(m), & \text{if } i = m, \\ \left(\begin{array}{c} n \\ m + 1 \end{array}\right) - (n - m)\#S(m), & \text{if } i = m + 1, \\ \left(\begin{array}{c} n \\ i \end{array}\right), & \text{if } i \geq m + 2. \end{cases}$$

This paper is organized as follows. In Section 2, we study stopping sets of an arbitrary AG code and give algebraic and geometric descriptions of stopping sets. In Section 3, we study the stopping sets and stopping set distributions of AG codes $C_{E}(D, G)$ from elliptic curves. We use the group structure of rational points of elliptic curves to present a complete characterization of stopping sets. It is shown that the stopping sets, the stopping set distribution and the stopping distance of the AG code from an elliptic curve can be reduced to the search, counting and decision versions of the subset sum problem in the group of rational points of the elliptic curve, respectively. We present the counting formula for the stopping set distributions of AG codes from elliptic curves. In particular, for some special cases, we determine explicitly the stopping set distributions of AG codes from elliptic curves. Finally, some conclusions and open problems are given in Section 4.
II. STOPPING SETS OF ALGEBRAIC GEOMETRY CODES

Let $X/\mathbb{F}_q$ be a geometrically irreducible smooth projective curve of genus $g$ over the finite field $\mathbb{F}_q$ with function field $\mathbb{F}_q(X)$, and $C_\Omega(D, G)$ the residue AG code from $X$. In this section, we study stopping sets and stopping set distributions of general residue AG codes and give algebraic and geometric descriptions of the stopping sets of $C_\Omega(D, G)$.

**Theorem 6.** A subset $A \subseteq [n]$ is a stopping set of $C_\Omega(D, G)$ if and only if
\[ \mathcal{L}(G - \sum_{j \in A} P_j) = \bigcup_{i \in A} \mathcal{L}(G - \sum_{j \in A \setminus \{i\}} P_j). \]

**Proof:** By the definition, $A \subseteq [n]$ is not a stopping set of $C_\Omega(D, G)$ if and only if there is some $f \in \mathcal{L}(G)$ such that $\text{ev}(f)|_A = (f(P_i))_{i \in A}$ has weight 1. That is, there is some $i \in A$ such that $f(P_i) \neq 0$ and $f(P_j) = 0$ for all $j \in A \setminus \{i\}$.

This is equivalent to saying that
\[ f \in \mathcal{L}(G - \sum_{j \in A \setminus \{i\}} P_j) \setminus \mathcal{L}(G - \sum_{j \in A} P_j). \]

So $A$ is a stopping set if and only if for any $i \in A$,
\[ \mathcal{L}(G - \sum_{j \in A} P_j) = \mathcal{L}(G - \sum_{j \in A \setminus \{i\}} P_j). \]

Since $\mathcal{L}(G - \sum_{j \in A} P_j) \subseteq \mathcal{L}(G - \sum_{j \in A \setminus \{i\}} P_j)$ for any $i \in A$, we have
\[ \mathcal{L}(G - \sum_{j \in A} P_j) = \bigcup_{i \in A} \mathcal{L}(G - \sum_{j \in A \setminus \{i\}} P_j) \iff \mathcal{L}(G - \sum_{j \in A} P_j) = \mathcal{L}(G - \sum_{j \in A \setminus \{i\}} P_j) \text{ for any } i \in A. \]

So the theorem holds.

As a simple corollary, we obtain

**Corollary 7.** (i) Any subset of $[n]$ with cardinality $\geq m + 2$ is a stopping set of $C_\Omega(D, G)$.

(ii) Any non-empty subset of $[n]$ with cardinality $\leq m - 2g + 1$ is not a stopping set of $C_\Omega(D, G)$.

**Proof:** (i) For any subset $A \subseteq [n]$ with cardinality $\geq m+2$, divisors $G - \sum_{j \in A \setminus \{i\}} P_j$ and $G - \sum_{j \in A} P_j$ are negative. So
\[ \mathcal{L}(G - \sum_{j \in A} P_j) = \bigcup_{i \in A} \mathcal{L}(G - \sum_{j \in A \setminus \{i\}} P_j) = \{0\}. \]

It follows from Theorem 6 that $A$ is a stopping set.
(ii) For any non-empty subset $A \subseteq [n]$ with cardinality $\leq m - 2g + 1$, by the Riemann-Roch theorem we have

$$\dim(\mathcal{L}(G - \sum_{j \in A} P_j)) = m - \#A - g + 1,$$

$$\dim(\mathcal{L}(G - \sum_{j \in A \setminus \{i\}} P_j)) = m - \#A - g + 2.$$

So

$$\mathcal{L}(G - \sum_{j \in A} P_j) \subsetneq \mathcal{L}(G - \sum_{j \in A \setminus \{i\}} P_j)$$

for all $i \in A$. It follows from Theorem 6 that $A$ is not a stopping set. Note that one can also give another proof of (ii) from Proposition 1, since the minimum distance of $C_{\Omega}(D, G)$ is at least $m - 2g + 2$.

If we represent the generalized Reed-Solomon codes as AG codes from the rational function field, then by Corollary 7, we also obtain Proposition 2 for the generalized Reed-Solomon codes.

Using the Riemann-Roch theorem, we give another description of stopping sets of AG codes $C_{\Omega}(D, G)$.

**Theorem 8.** A subset $A \subseteq [n]$ is a stopping set of $C_{\Omega}(D, G)$ if and only if for any $i \in A$, there exists an effective divisor $E_i$ with $P_i \notin \text{Supp}(E_i)$ such that

$$K - G + \sum_{j \in A} P_j \sim E_i,$$

where $K$ is a canonical divisor on $X$ and $\sim$ means that two divisors are linearly equivalent, i.e., the difference between the two divisors is a principal divisor.

**Proof:** From the proof of Theorem 6, a subset $A \subseteq [n]$ is a stopping set if and only if for any $i \in A$,

$$\dim \mathcal{L}(G - \sum_{j \in A} P_j) = \dim \mathcal{L}(G - \sum_{j \in A \setminus \{i\}} P_j).$$

The Riemann-Roch theorem states that for any divisor $V$, we have

$$\dim \mathcal{L}(V) = \deg(V) - g + 1 + \dim \mathcal{L}(K - V).$$

So a subset $A \subseteq [n]$ is a stopping set if and only if for any $i \in A$,

$$\dim \mathcal{L}(K - G + \sum_{j \in A} P_j) = \dim \mathcal{L}(K - G + \sum_{j \in A \setminus \{i\}} P_j) + 1.$$

It is equivalent to that for any $i \in A$, there exists

$$f \in \mathcal{L}(K - G + \sum_{j \in A} P_j) \setminus \mathcal{L}(K - G + \sum_{j \in A \setminus \{i\}} P_j).$$

The last statement is equivalent to that for any $i \in A$, there exists an effective divisor $E_i$ with $P_i \notin \text{Supp}(E_i)$.
Supp(\(E_i\)) such that
\[
K - G + \sum_{j \in A} P_j \sim E_i. 
\]
Indeed, \(E_i = \text{div}(f) + K - G + \sum_{j \in A} P_j\).

By Theorem 8, we immediately have a sufficient condition for a subset to be a stopping set.

**Corollary 9.** Keep notation as above. Let \(A\) be a subset of \([n]\). If \(K - G + \sum_{j \in A} P_j \sim E\) for some effective divisor \(E\) whose support has no intersection with \(\{P_i \mid i \in A\}\), then \(A\) is a stopping set.

### III. Stopping Sets and Stopping Set Distributions of AG Codes from Elliptic Curves

In the previous section, for the general AG code \(C_\Omega(D, G)\), we have seen that there is a gap, \(\text{deg}(G) - 2g + 2 < i \leq \text{deg}(G) + 1\), where in general we have not determined whether a subset with cardinality \(i\) is a stopping set or not. In this section, we consider a class of special AG codes, AG codes constructed from elliptic curves.

Let \(X = E\) be an elliptic curve over the finite field \(\mathbb{F}_q\) with a rational point \(O\). Endow \(E(\mathbb{F}_q)\) a group structure with the zero element \(O\). Let \(D = \{P_1, P_2, \ldots, P_n\}\) be a subset of the set \(E(\mathbb{F}_q)\) such that \(O \notin D\). Let \(G = mO\) (\(0 < m < n\)).

In general, if \(G\) is a divisor of degree \(m\) on \(E\), then for any rational point \(Q \in E(\mathbb{F}_q)\), as \(\text{deg}(G - (m - 1)Q) = 1\), by the Riemann-Roch theorem, there exists one and only one rational point \(P \in E(\mathbb{F}_q)\) such that \(G \sim (m - 1)Q + P\). Suppose there exist rational points \(Q, P\) such that \(G \sim (m - 1)Q + P\) and \(P, Q \notin D\). Let \(G' = (m - 1)Q + P\). Then the codes \(C_\Omega(D, G)\) and \(C_\Omega(D, G')\) are equivalent [31, Proposition 2.2.14]. And the dual codes \(C_\Omega(D, G)\) and \(C_\Omega(D, G')\) are also equivalent. Here two linear codes \(C_1, C_2 \subseteq \mathbb{F}_q^n\) are said to be equivalent if there is a vector \(a = (a_1, \ldots, a_n) \in (\mathbb{F}_q^*)^n\) such that
\[
C_2 = a \cdot C_1 = \{(a_1c_1, \ldots, a_nc_n) \mid (c_1, \ldots, c_n) \in C_1\}.
\]
It is easy to see that two equivalent codes have the same stopping sets and hence the same stopping set distributions. So to study the stopping sets and the stopping set distribution of \(C_\Omega(D, G)\), it suffices to determine all the stopping sets and the stopping set distribution of \(C_\Omega(D, (m - 1)Q + P)\). In this case, we use \(Q\) to define the group \(E(\mathbb{F}_q)\) with the zero element \(Q\). Then all results in this paper hold similarly for \(C_\Omega(D, G)\) with \(G \sim (m - 1)Q + P\) such that \(P, Q \notin D\).

Note that \(g = 1\) for elliptic curves. According to Corollary 7, any subset of \([n]\) with cardinality \(\geq m + 2\) is a stopping set and any non-empty subset of \([n]\) with cardinality \(\leq m - 1\) is not a stopping set. So it is enough to consider the subsets of \([n]\) with cardinality \(m\) and \(m + 1\). Below we use the group \(E(\mathbb{F}_q)\) [27, 30] to give a description of these two classes of stopping sets with cardinality \(m\) and \(m + 1\), respectively.

(i) Suppose \(A \subseteq [n]\) with cardinality \(m + 1\) is not a stopping set. Then there are some \(i \in A\) and
$f \in \mathcal{L}(G)$ such that

$$f \in \mathcal{L}(G - \sum_{j \in A \setminus \{i\}} P_j) \setminus \mathcal{L}(G - \sum_{j \in A} P_j).$$

Note that

$$\deg(G - \sum_{j \in A \setminus \{i\}} P_j) = m - m = 0,$$

and

$$\text{div}(f) \geq -G + \sum_{j \in A \setminus \{i\}} P_j.$$ 

Since both sides have degree zero, so

$$\text{div}(f) = -G + \sum_{j \in A \setminus \{i\}} P_j = \sum_{j \in A \setminus \{i\}} (P_j - O).$$

In this case, $A \subseteq [n], \#A = m + 1$, is not a stopping set if and only if there exists some $i \in A$ such that the sum $\sum_{j \in A \setminus \{i\}} P_j$ in the group $E(\mathbb{F}_q)$ is $O$.

(ii) Suppose $A \subseteq [n]$ with cardinality $m$ is a stopping set. By Theorem 6, for any $i \in A$, we have

$$\mathcal{L}(G - \sum_{j \in A \setminus \{i\}} P_j) = \mathcal{L}(G - \sum_{j \in A} P_j).$$

But

$$\deg(G - \sum_{j \in A \setminus \{i\}} P_j) = 1 \geq 2g - 1 = 1,$$

by the Riemann-Roch theorem, there exists some $f \in \mathbb{F}_q(E)$ such that

$$0 \neq f \in \mathcal{L}(G - \sum_{j \in A \setminus \{i\}} P_j) = \mathcal{L}(G - \sum_{j \in A} P_j).$$

So

$$\text{div}(f) = G - \sum_{j \in A} P_j = \sum_{j \in A} (O - P_j).$$

This is equivalent to

$$\sum_{j \in A} P_j = O$$

in the group $E(\mathbb{F}_q)$. Conversely, let $A \subseteq [n]$ with cardinality $m$ such that $\sum_{j \in A} P_j = O$. Since the zero divisor $K = 0$ is a canonical divisor for elliptic curves, we have

$$K - G + \sum_{j \in A} P_j \sim 0.$$

By Corollary 9, $A$ is a stopping set.

From the argument above, we obtain the following partial results of the main theorem in the introduction.
Theorem 10. Let $E$ be an elliptic curve over the finite field $\mathbb{F}_q$, $D = \{P_1, P_2, \cdots, P_n\}$ a subset of $E(\mathbb{F}_q)$ such that the zero element $O \notin D$ and let $G = mO$ ($0 < m < n$). The non-empty stopping sets of the residue code $C_\Omega(D, G)$ are given as follows:

(i) Any subset of $[n]$ with cardinality $\leq m - 1$ is not a stopping set.

(ii) Any subset of $[n]$ with cardinality $\geq m + 2$ is a stopping set.

(iii) $A \subseteq [n]$, $\#A = m + 1$, is a stopping set if and only if for all $i \in A$, the sum $\sum_{j \in A \setminus \{i\}} P_j \neq O$.

(iv) $A \subseteq [n]$, $\#A = m$, is a stopping set if and only if $\sum_{j \in A} P_j = O$.

Let us give an example to illustrate the theorem.

Example 11. Let $E$ be an elliptic curve defined over $\mathbb{F}_5$ by the equation

$$y^2 = x^3 + x + 1.$$ 

Then $E$ has 9 rational points: the infinity point $O$ and $P_1 = (0, 1)$, $P_2 = (4, 2)$, $P_3 = (2, 1)$, $P_4 = (3, 4)$, $P_5 = (3, 1)$, $P_6 = (2, -1)$, $P_7 = (4, -2)$, $P_8 = (0, -1)$. Using Group Law Algorithm 2.3 in [30], one can check that $E(\mathbb{F}_5)$ forms a cyclic group with $P_i = [i]P_1$. Let $D = \{P_1, P_2, \cdots, P_8\}$ and $G = 3O$.

By Corollary 9 and Theorem 10, all nonempty stopping sets of $C_\Omega(D, G)$ are given as follows:

(i) subsets of $[n]$, with cardinality $\geq 5$;

(ii) $\{1, 2, 3, 7\}, \{1, 2, 3, 8\}, \{1, 2, 4, 5\}, \{1, 2, 4, 7\}, \{1, 2, 5, 7\}, \{1, 2, 5, 8\}, \{1, 2, 7, 8\}, \{1, 3, 4, 6\}, \{1, 3, 4, 7\}, \{1, 3, 4, 8\}, \{1, 3, 6, 7\}, \{1, 3, 6, 8\}, \{1, 4, 5, 6\}, \{1, 4, 5, 7\}, \{1, 4, 5, 8\}, \{1, 4, 6, 7\}, \{1, 4, 7, 8\}, \{1, 5, 6, 8\}, \{1, 5, 7, 8\}, \{1, 6, 7, 8\}, \{2, 3, 5, 6\}, \{2, 3, 5, 7\}, \{2, 3, 5, 8\}, \{2, 3, 6, 7\}, \{2, 3, 6, 8\}, \{2, 4, 5, 6\}, \{2, 4, 5, 7\}, \{2, 4, 5, 8\}, \{2, 4, 6, 7\}, \{2, 4, 7, 8\}, \{2, 5, 6, 8\}, \{2, 5, 7, 8\}, \{2, 6, 7, 8\}, \{3, 4, 5, 6\}, \{3, 4, 5, 7\}, \{3, 4, 5, 8\}, \{3, 4, 6, 7\}, \{3, 5, 6, 8\}, \{4, 5, 7, 8\};

(iii) $\{1, 2, 6\}, \{1, 3, 5\}, \{2, 3, 4\}, \{3, 7, 8\}, \{4, 6, 8\}, \{5, 6, 7\}$.

So the stopping set distribution of $C_\Omega(D, G)$ with the parity-check matrix $H^*$ is

$$T_i(H^*) = \begin{cases} 
1, & \text{if } i = 0, \\
6, & \text{if } i = 3, \\
40, & \text{if } i = 4, \\
{8 \choose i}, & \text{if } i \geq 5, \\
0, & \text{otherwise}. 
\end{cases}$$

Also, the minimum distance of the code $C_\Omega(D, G)$ is 3 by Proposition 1.

Theorem 10 describes all the stopping sets of residue AG codes from elliptic curves. Next, we establish
the relationship between the set of stopping sets with cardinality \( m \) and the set of stopping sets with cardinality \( m + 1 \).

Denote by \( S(m) \) and \( S(m + 1) \) the two sets of stopping sets with cardinality \( m \) and \( m + 1 \) in the cases (iv) and (iii) in Theorem 10, respectively. Let \( S^+(m) \) be the extended set of \( S(m) \) defined as follows

\[
S^+(m) = \bigcup_{A \in S(m)} \{ A \cup \{ i \} : i \in [n] \setminus A \}.
\]

**Theorem 12.** Notation as above. We have

\[
S(m + 1) \cap S^+(m) = \emptyset,
\]

and

\[
S(m + 1) = \{ \text{all subsets of } [n] \text{ with cardinality } m + 1 \} \setminus S^+(m).
\]

Moreover, the union in the definition of \( S^+(m) \) is a disjoint union. Hence

\[
\#S(m + 1) = \binom{n}{m+1} - \#S^+(m)
= \binom{n}{m+1} - (n - m)\#S(m).
\]

**Proof:** First, \( S(m + 1) \cap S^+(m) = \emptyset \) is obvious by parts (iii) and (iv) of Theorem 10. So

\[
S(m + 1) \subseteq \{ \text{all subsets of } [n] \text{ with cardinality } m + 1 \} \setminus S^+(m).
\]

On the other hand, for any \( A \notin S(m + 1) \) and \( \#A = m + 1 \), by Theorem 10 (iii), there is some \( i \in A \) such that \( \sum_{j \in A \setminus \{i\}} P_j = O \). By Theorem 10 (iv), \( A \setminus \{i\} \in S(m) \). So

\[
A = (A \setminus \{i\}) \cup \{i\} \in S^+(m).
\]

Hence

\[
S(m + 1) = \{ \text{all subsets of } [n] \text{ with cardinality } m + 1 \} \setminus S^+(m).
\]

If there exist \( A \in S(m), A' \in S(m), i \notin A \) and \( i' \notin A' \) such that

\[
A \cup \{i\} = A' \cup \{i'\} \in S^+(m).
\]

Then we have \( i \in A', i' \in A \) and \( A \setminus \{i'\} = A' \setminus \{i\} \).

Since

\[
\sum_{j \in A} P_j = \sum_{j \in A'} P_j = O
\]

we get \( P_i = P_{i'} \). So

\[
A = A', \quad i = i'.
\]
That is, the union in the definition of $S^+(m)$ is a disjoint union. And the formula
\[
\#S(m + 1) = \binom{n}{m+1} - \#S^+(m) = \binom{n}{m+1} - (n - m)\#S(m)
\]
follows immediately.

**Remark 13.** The above theorem shows how we can get $S(m + 1)$ from $S(m)$. Conversely, if we know $S(m + 1)$, then by the above theorem, we can exclude $S(m + 1)$ from the set of all subsets of $[n]$ with $m + 1$ elements to get $S^+(m)$. For any $I \in S^+(m)$, we calculate $\sum_{i \in I} P_i$. Then by Theorem 10 (iv), there is some index $j(I) \in I$ such that
\[
\sum_{i \in I} P_i = P_{j(I)}
\]
By the definitions of $S(m)$ and $S^+(m)$, we have
\[
S(m) = \{I \setminus \{j(I)\} \mid I \in S^+(m)\}
\]
In the above example, by Theorem 10 (iv), $S(3)$ consists of all the subsets of $[8]$ whose sums have 9 as a divisor. Then by Theorem 12, $S(4)$ follows immediately from $S(3)$.

The following corollary follows immediately from Proposition 1, Theorems 10 and 12.

**Corollary 14.** Notation as above. The minimum distance and the stopping distance of the residue AG code $C_\Omega(D, G)$ is $\deg(G)$ or $\deg(G) + 1$. More explicitly, if $\#S(m) > 0$, then we have the stopping distance
\[
s(C_\Omega(D, G)) = d(C_\Omega(D, G)) = m = \deg(G)
\]
If $\#S(m) = 0$, then we have $\#S(m + 1) > 0$ and hence
\[
s(C_\Omega(D, G)) = d(C_\Omega(D, G)) = m + 1 = \deg(G) + 1
\]
Let $G$ be an abelian group with zero element $O$ and $D$ a finite subset of $G$. For an integer $0 < k < |D|$ and an element $b \in D$ we denote
\[
N_G(k, b, D) = \#\{S \subseteq D \mid \#S = k \text{ and } \sum_{x \in S} x = b\}
\]
Computing $N_G(k, b, D)$ is called a counting version of the $k$-subset sum problem ($k$-SSP). In general, a counting $k$-SSP is $\text{NP}$-hard [4]. If there is no confusion, we simply denote
\[
N(k, b, D) = N_G(k, b, D)
\]
**Remark 15.** By the above theorem, for a general subset $D \subseteq E(F_q)$, to decide whether $\#S(m) > 0$ is the decision $m$-subset sum problem in $E(F_q)$. It is known that the decision $m$-subset sum problem in $E(F_q)$ in general is $\text{NP}$-hard under $\text{RP}$-reduction [3]. So to compute the stopping distance of $C_\Omega(D, G)$
is NP-hard under RP-reduction.

But for a subset $D \subseteq E(\mathbb{F}_q)$ with special algebraic structure, it is possible to give an explicit formula for $\#S(m) = N(m, O, D)$, and hence explicit formulae for $\#S(m+1)$ and the whole stopping set distribution by Theorem 12. In the following, we consider special subsets $D = P \setminus \{O\}$ for some subgroup $P$ of $E(\mathbb{F}_q)$. In particular, recall that $C_\Omega(D, G)$ is called the standard elliptic code if $D = E(\mathbb{F}_q) \setminus \{O\}$.

**Proposition 16** ([19, 23]). Let $G$ be a finite abelian group. For $b \in G$, we have

$$N(i, b, G \setminus \{0\}) = \frac{1}{N} \sum_{s \mid \exp(G)} (-1)^i \left[\frac{N}{s} - 1\right] \cdot \sum_{d \mid \gcd(e(b), s)} \mu(s/d) \#G[d] .$$

where $N = \#G$, $\exp(G)$ is the exponent of $G$, $e(b) = \max\{d \mid d \mid \exp(G), b \in dG\}$, $\mu$ is the Möbius function and $G[d]$ is the $d$-torsion subgroup of $G$.

Set $G = P$ a subgroup of $E(\mathbb{F}_q)$ in Proposition 16. Let $N = |P| = n + 1$ and $D = P \setminus \{O\}$. Then we have

**Theorem 17.** The number of stopping sets of $C_\Omega(D, mO)$ with cardinality $m$ is

$$\#S(m) = \frac{1}{N} \sum_{s \mid \exp(P)} (-1)^{m + \lfloor \frac{s}{m} \rfloor} \left[\frac{N}{s} - 1\right] \cdot \sum_{d \mid s} \mu(s/d) \#P[d] .$$

So together with Theorems 10 and 12, we obtain Theorem 5.

It is well-known that the group $E(\mathbb{F}_q)$ of rational points is isomorphic to

$$E(\mathbb{F}_q) \cong \mathbb{Z}/m_1\mathbb{Z} \oplus \mathbb{Z}/m_2\mathbb{Z} ,$$

for some integers $m_1 | m_2$. Then by Theorems 10, 12 and 17, we can determine the stopping set distribution of the standard residue AG code $C_\Omega(D, mO)$ from any elliptic curve $E/\mathbb{F}_q$ provided that we know the group structure of $E(\mathbb{F}_q)$. Explicitly, we can compute $\#S(3)$ in Example 11:

$$\#S(3) = \frac{1}{9} \sum_{s \mid 9} (-1)^{3 + \lfloor \frac{s}{3} \rfloor} \left[\frac{9}{s} - 1\right] \cdot \sum_{d \mid s} \mu(s/d) \#\mathbb{Z}/9\mathbb{Z}[d] = \frac{1}{9} \left(\binom{3}{1} + \binom{3}{1} (3 - 1) - (9 - 3)\right) = 6 .$$

So $\#S(4) = \binom{8}{4} - (8 - 3)\#S(3) = 40$. This agrees with the exhausting calculation in Example 11.

If we take special subgroups of $E(\mathbb{F}_q)$, then we have the following corollary.

**Corollary 18.** Notations as above.

(i) If we take

$$P \cong \mathbb{Z}/p^i\mathbb{Z}$$

for some prime integer $p$ and integer $t \geq 1$, then
\[
\#S(m) = \frac{1}{p^t} \left( \binom{p^t - 1}{m} + (-1)^m(p^t - p^{\lceil \log_p(m) \rceil}) + \sum_{i=1}^{\lfloor \log_p(m) \rfloor} (-1)^{m+i} \frac{m}{p^i} \binom{p^{t-i} - 1}{\lfloor \frac{m}{p^i} \rfloor} \right).
\]

In particular, if $t = 1$, then
\[
\#S(m) = \frac{1}{p} \left( \binom{p - 1}{m} + (-1)^m(p - 1) \right).
\]

If $t = 2$, then
\[
\#S(m) = \frac{1}{p} \left( \binom{p - 1}{m} + (-1)^m(p^2 - p) + (-1)^{m+1} \frac{m}{p} \binom{p - 1}{\lfloor \frac{m}{p} \rfloor} \right).
\]

(ii) If we take
\[
P \cong \mathbb{Z}/p^{t_1} \mathbb{Z} \oplus \mathbb{Z}/p^{t_2} \mathbb{Z}
\]
for some prime integer $p$ and integers $1 \leq t_1 \leq t_2$, then
\[
\#S(m) = \frac{1}{p^{t_1+t_2}} \left( \binom{p^{t_1+t_2} - 1}{m} + \sum_{i=1}^{t_2} (-1)^{m+i} \frac{m}{p^i} \binom{p^{t_2-i} - 1}{\lfloor \frac{m}{p^i} \rfloor} (p^i - 1) \right).
\]

(iii) If we take
\[
P \cong \mathbb{Z}/p_1^{t_1} \mathbb{Z} \oplus \mathbb{Z}/p_2^{t_2} \mathbb{Z}
\]
for two distinct prime integers $p_1, p_2$ and integers $t_1, t_2 \geq 1$, then
\[
\#S(m) = \frac{1}{p_1^{t_1}p_2^{t_2}} \left( \binom{p_1^{t_1}p_2^{t_2} - 1}{m} + (p_1 - 1)(p_2 - 1) \cdot \sum_{i=1}^{t_1} \sum_{j=1}^{t_2} (-1)^{m+i} \frac{m}{p_1^i p_2^j} \binom{p_1^{i-1}p_2^{j-1} - 1}{\lfloor \frac{m}{p_1^i p_2^j} \rfloor} \right)
\]
\[
\quad \quad \quad + \sum_{i=1}^{t_1} (-1)^{m+i} \frac{m}{p_1^i} \binom{p_1^{i-1}p_2^{t_2} - 1}{\lfloor \frac{m}{p_1^i} \rfloor} (p_1^{t_2} - p_1^{i-1}) + \sum_{j=1}^{t_2} (-1)^{m+j} \frac{m}{p_2^j} \binom{p_1^{t_1}p_2^{j-1} - 1}{\lfloor \frac{m}{p_2^j} \rfloor} (p_2^{t_1} - p_2^{j-1}) \right).
\]

IV. CONCLUSION

In this paper, we study stopping sets and stopping set distributions of residue algebraic geometry codes $C_\Omega(D, G)$. Two descriptions of stopping sets of residue algebraic geometry codes are presented. In particular, there is a gap $\deg(G) - 2g + 2 \leq i \leq \deg(G) + 1$ where in general we do not know whether a subset with cardinality $i$ is a stopping set or not. In the case $g = 0$, there is no gap and we have a complete understanding. In the case $g = 1$, using the group structure of rational points of elliptic curves, we can characterize all the stopping sets of algebraic geometry codes from elliptic curves. Then determining the stopping sets, the stopping set distribution and the stopping distance of $C_\Omega(D, G)$ are reduced to $\deg(G)$-subset sum problems in finite abelian groups. In the case $g > 1$, only partial results can be obtained. It is still not known how to compute the stopping set distribution. For further work, there are two interesting problems:
(i) There are some papers contributing to compute the stopping redundancy of MDS codes [10, 12, 28]. For AG codes from elliptic curves, we have seen that the code is very closed to be MDS, i.e., MDS or near-MDS [29] (an \([n, k, d]\) linear code is called near-MDS if \(d = n - k\) and the dual distance \(d^\perp = k\)). So how about the stopping redundancy of AG codes from elliptic curves?

(ii) In this paper, we have determined the stopping set distributions of AG codes from elliptic curves with the parity-check matrix \(H^*\). Can we give optimal parity-check matrices for AG codes from elliptic curves?
