Dedicated to Professor Jean Mawhin for his coming 75th birthday

Abstract
Using Mawhin’s coincidence degree theory, we obtain some new continuation theorems which are designed to have as a natural application the study of the periodic problem for cyclic feedback type systems. We also discuss some examples of vector ordinary differential equations with a $\phi$-Laplacian operator where our results can be applied.

1 Introduction
The aim of this paper is to apply Mawhin’s coincidence degree theory in the study of the periodic boundary value problem for some classes of first order differential systems of cyclic feedback type. From this point of view, our work continues the research initiated in [6] and is also partially inspired by the results in [16] on periodic ODE systems with a $\phi$-Laplacian differential operator.

Roughly speaking, by a “cyclic system” we usually mean a first order system of ordinary differential equations where the time evolution of the $j$-th component
y_j(t) mainly depends upon the pair \((y_j(t), y_j(t))\). Therefore, the components are ordered in a cyclic manner, so that we consider \(n \equiv 0\) for a system of \(n\) variables. Accordingly, such systems usually take a form as

\[
y'_j = g_j(y_{j-1}, y_j), \quad j = 1, \ldots, n,
\]

(1.1)

where we agree to interpret \(y_0\) as \(y_n\) (cf. [15]). More general models consider also the case where \(g_j = g_j(y_{j-1}, y_j, y_{j+1})\), which is a typical case of a system describing nearest neighbor interactions. The term “feedback” usually refers to a monotonicity assumption of the form \(\frac{\partial g_j(y_{j-1}, y_j)}{\partial y_j - 1} > 0\) or \(\frac{\partial g_j(y_{j-1}, y_j)}{\partial y_j - 1} < 0\), which reflects the fact that the variable \(y_{j-1}\) has a positive or negative effect on the growth of the \(j\)-th variable \(y_j\). These features explain the reason why first order differential systems with a cyclic feedback structure arise in several different contexts, both theoretic and applied. As observed in [15], such systems naturally appear in the investigation of biological models (for instance, cellular control systems) as well as in the study of delay-differential equations or reaction-diffusion equations (after a discretization procedure).

Up to a relabeling of the variables in equation (1.1), namely setting \(x_i := y_{n+1-i}\), we get an equivalent system of the form

\[
x'_i = f_i(x_i, x_{i+1}), \quad i = 1, \ldots, n,
\]

(1.2)

with \(f_i = g_j\) for \(i + j = n + 1\). In view of the applications that we are going to present in this article, it will be more convenient for us to consider cyclic systems of the form (1.2). For many concrete examples, in some of the equations of system (1.2) there is no dependence of \(f_i\) upon the \(i\)-th variable or such dependence can be neglected. Two typical examples are the following.

Consider a \(n\)-th order differential equation of the form

\[
x^{(n)}(t) + h(t, x, x', \ldots, x^{(n-1)}) = 0,
\]

(1.3)

which can be written as

\[
\begin{cases}
x'_i = x_{i+1}, & i = 1, \ldots, n - 1, \\
x'_n = -h(t, x_1, \ldots, x_n).
\end{cases}
\]

(1.4)

In such a case \(f_i(x_i, x_{i+1}) = x_{i+1}\) for \(i = 1, \ldots, n - 1\), so that the first \(n - 1\) equations in the cyclic system (1.2) are strongly simplified. On the other hand, this example shows that there are cases in which the last equation in (1.2) may be more complicated than \(x'_n = f_n(x_n, x_1)\).

In some ODE models for population dynamics it is rather common to encounter Kolmogorov systems of the form

\[
u'_i = u_i K_i(u_{i+1}), \quad i = 1, \ldots, n \equiv 0.
\]

(1.5)

A typical two-dimensional case is given by the Lotka-Volterra predator-prey equation

\[
\begin{cases}
u' = u(a - bv) \\
v' = v(-c + du).
\end{cases}
\]

2
Since we are looking for positive solutions, we can perform the change of variable $x_i(t) = \log(u_i(t))$ and transform (1.5) to the equivalent cyclic feedback system

$$x'_i = K_i(\exp(x_{i+1})), \quad i = 1, \ldots, n \equiv 0,$$

which is of the form of (1.2) with $f_i$ independent on the variable $x_i$. This latter model suggests the interest to deal also with the non-autonomous counterpart of system (1.2), by assuming an explicit dependence of some of the coefficients on the time variable. This situation naturally occurs in the study of some Kolmogorov systems, like the Lotka-Volterra one, in which one can consider a seasonal dependence on the coefficients.

In view of the above remarks, we plan to investigate a class of cyclic feedback systems related to (1.2) which have a simpler form in the first $n - 1$ components but, on the other hand, allow to consider a more general dependence for the last equation, in order to apply our results to equations of the form (1.4) as well.

With this respect, we study a system of the form

$$\begin{cases}
  x'_1 = g_1(x_2) \\
  x'_2 = g_2(x_3) \\
  \vdots \\
  x'_{n-1} = g_{n-1}(x_n) \\
  x'_n = h(t, x_1, \ldots, x_n),
\end{cases} \quad (\mathcal{C})$$

where throughout the paper we suppose that $g_1, \ldots, g_{n-1}$ are continuous functions and $h$ is $T$-periodic in the $t$-variable and satisfies the Carathéodory assumptions.

A powerful topological tool to produce existence and multiplicity results of periodic solutions is Mawhin’s coincidence degree theory, which allows to apply a topological degree type approach to problems which can be written as an abstract operator equation of the form $Lx = Nx$, where $L$ is a linear non-invertible operator and $N$ is a nonlinear one acting on a Banach space $X$. In order to present the next results, we take

$$X := C_T := \{ x \in C([0, T], \mathbb{R}^m): x(0) = x(T) \},$$

with the standard sup-norm $\| \cdot \|_{\infty}$.

In the frame of coincidence degree theory, the main existence result for the periodic problem

$$\begin{cases}
  x' = F(t, x) \\
  x(0) = x(T),
\end{cases} \quad (\mathcal{P})$$

where $F: [0, T] \times \mathbb{R}^m \to \mathbb{R}^m$ is a Carathéodory vector field, is Mawhin’s continuation theorem (cf. [19, Théorème 2] or [23, Theorem 4.1]), which reads as follows (we denote by “deg$_B$” the Brouwer degree).

**Theorem 1.1.** Let $\Omega \subseteq X$ be an open bounded set and suppose that:

- for each $\lambda \in ]0, 1[$ there is no solution of problem

$$\begin{cases}
  x' = \lambda F(t, x) \\
  x(0) = x(T)
\end{cases}$$
with \( x \in \partial \Omega \):

- the averaged map \( F^\#: z \mapsto \frac{1}{T} \int_0^T F(t, z) \, dt \) has no zeros on \( \partial \Omega \cap \mathbb{R}^m \) and \( \deg_B(F^\#, \Omega \cap \mathbb{R}^m, 0) \neq 0 \).

Then, problem \( (\mathcal{P}) \) has a solution in \( \bar{\Omega} \).

A second continuation theorem was proposed in \[5\] and extended to delay-differential equations (with a different proof) in \[1\]. It concerns the case in which the homotopic parameter \( \lambda \) is used to modify the original system to an autonomous one. More precisely, we suppose that there exists a Carathéodory vector field \( \mathcal{F} = \mathcal{F}(t, x, \lambda): [0, T] \times \mathbb{R}^m \times [0, 1] \to \mathbb{R}^m \) such that

\[
\mathcal{F}(t, x, 0) = F_0(x), \quad \mathcal{F}(t, x, 1) = F(t, x).
\]

The corresponding existence result can be stated as follows (cf. \[5, \text{Theorem 2}\]).

**Theorem 1.2.** Let \( \Omega \subseteq X \) be an open bounded set and suppose that:

- for each \( \lambda \in [0, 1[ \) there is no solution of problem

\[
\begin{cases}
  x' &= \mathcal{F}(t, x, \lambda) \\
  x(0) &= x(T)
\end{cases}
\]

with \( x \in \partial \Omega \);

- \( \deg_B(F_0, \Omega \cap \mathbb{R}^m, 0) \neq 0 \).

Then, problem \( (\mathcal{P}) \) has a solution in \( \bar{\Omega} \).

Both these results extend to higher order differential systems of the form \( (1.3) \). In particular, both the results and especially Theorem 1.1 have found a great number of applications to the \( T \)-periodic problem associated with the vector second order differential equation

\[
u'' + g(t, u, u') = 0,
\]

where \( g: [0, T] \times \mathbb{R}^d \times \mathbb{R}^d \to \mathbb{R}^d \) is a Carathéodory function.

The study of ordinary and partial differential equations involving nonlinear differential operators (like the \( p \)-Laplacian, the curvature or the Minkowski operators), started in the mid-twentieth century, has shown a tremendous growth in the last decades. Applications of topological degree methods to these equations strongly motivated the search of new topological tools, such as the continuation theorems for strongly nonlinear operators (see, for instance, \[9\] for some pioneering works in this direction). For the periodic boundary value problem associated with non-autonomous ODEs, Manásevich and Mawhin developed in \[16\] new continuation theorems for the second order vector nonlinear equation

\[
(\phi(u'))' + g(t, u, u') = 0. \quad (1.6)
\]

(1) New applications were also obtained by the same authors in \[17, 18\] as well as by Mawhin in \[25\]. The two main continuation theorems in \[16\] extend Theorem 1.1 and Theorem 1.2, respectively, to the above periodic problem, considering, instead of the linear differential operator \( u \mapsto -u'' \), the strongly nonlinear
operator \( u \mapsto -(\phi(u'))' \). The approach in [16] requires that \( \phi: \mathbb{R}^d \to \mathbb{R}^d \) is a homeomorphism with \( \phi(0) = 0 \) satisfying some additional technical growth conditions (compare with (H1) and (H2) in Remark 3.2). These continuation theorems concern, respectively, the study of the homotopic equations

\[
(\phi(u'))' + \lambda g(t, u, u') = 0, \quad \lambda \in [0, 1],
\]

(in analogy to Theorem 1.1) or

\[
(\phi(u'))' + \tilde{g}(t, u, u', \lambda) = 0, \quad \lambda \in [0, 1],
\]

with

\[
\tilde{g}(t, u, v, 1) = g(t, u, v) \quad \text{and} \quad \tilde{g}(t, u, v, 0) = g_0(u, v)
\]

(in analogy to Theorem 1.2). As far as we know, it seems that the problem whether the technical conditions (H1) and (H2) considered in [16, 17, 18, 25] are necessary or can be removed has not yet been completely solved. Recently, a different point of view has been considered by Lu and Lu in [14] where, for the mean curvature operator equation, the authors have applied Mawhin’s continuation Theorem 1.1 directly to the first order system

\[
\begin{aligned}
&x_1' = \phi^{-1}(x_2) \\
&x_2' = -g(t, x_1, \phi^{-1}(x_2)).
\end{aligned}
\]

(1.8)

To be more precise, we have to remark that in the equation considered in [14] the function \( g \) does not depend on \( u' \) and therefore the treatment can be simplified. Clearly, the application of Theorem 1.1 to system (1.8) involves the study of the parameter-dependent system

\[
\begin{aligned}
&x_1' = \lambda \phi^{-1}(x_2) \\
&x_2' = -\lambda g(t, x_1, \phi^{-1}(x_2)), \quad \lambda \in ]0, 1[,
\end{aligned}
\]

which, in turns, corresponds to equation

\[
(\phi(u'/\lambda))' + \lambda g(t, u, u'/\lambda) = 0, \quad \lambda \in [0, 1],
\]

which looks different from (1.7) and, apparently, more complicated.

If we write equation (1.7) as a first order system in \( \mathbb{R}^{2d} \), the natural choice would be that of

\[
\begin{aligned}
&x_1' = \phi^{-1}(x_2) \\
&x_2' = -g(t, x_1, \phi^{-1}(x_2)), \quad \lambda \in ]0, 1[.
\end{aligned}
\]

(1.9)

The advantage in dealing with such a system is that we only require that \( \phi \) is a homeomorphism (without the need of other technical conditions on \( \phi \), as considered in [16]). On the other hand, Theorem 1.1 does not apply directly to (1.9) and this may represent a motivation to try to extend the classical Mawhin’s continuation theorem to a form in which the homotopic parameter \( \lambda \) appears only on some components of the differential system. A first aim of the present paper is to pursue this line of research and, indeed, we will provide a version of Theorem 1.1 which is suitable for applications to cyclic feedback systems of the form (C), via an homotopy of the form (1.9), when applied to (1.8).
Our proposal for a new continuation theorem is in any case within the setting of Mawhin’s coincidence degree theory and it will be presented as a general theorem for operator equations of coincidence type that mimics at the abstract level some typical properties of the cyclic systems.

With this respect, the plan of the paper is the following. In Section 2 we present an application of the theory of coincidence degree in the setting of a system of operator equations, namely as coincidence equations involving operators defined in product spaces. We assume the reader familiar with the basics of Mawhin’s coincidence degree, as presented in some classical works like [10, 21, 23]. In any case, when necessary, we shall recall some crucial properties. The key ingredient in our proofs is the reduction formula, a basic tool also in the original applications of the theory (see [19] and also [26, 27] for some recent developments), which allows to relate a Leray-Schauder type degree in a normed space with a Brouwer degree in a finite-dimensional space. Accordingly, our main results in Section 2 are Theorem 2.1, where we perform an abstract homotopy of the form (1.9), and the subsequent Lemma 2.4, where we provide a precise formula for the computation of the degree. Such results have an immediate application to the periodic problem and therefore in Section 3 we give some existence theorems of continuation type for system (C) which are analogous to Theorems 1.1 (see Theorem 3.1 and Theorem 3.2). In the same section we produce, as a consequence of our main results, a continuation theorem for \( \phi \)-Laplacian differential systems of the form (1.6) which involves the study of (1.7). Our contribution for this kind of equations is Theorem 3.4 which is exactly Manásevich-Mawhin theorem [16, Theorem 3.1], with the only difference that with our approach we can avoid some technical conditions on \( \phi \) which were assumed in [16]. We also provide an example of a general type of higher dimensional \( \phi \)-map where our result can be applied. In Section 4 we discuss a second type of continuation theorems which are essentially based on Theorem 1.2. More precisely, we consider the case when the admissible homotopy transforms a non-autonomous system of the form (C) into an autonomous one where the coincidence degree can be computed using the theorems in [1] and [5] (these auxiliary results are recalled in a final appendix together with a more general version suitable for our applications). Again our purpose is to show that, when a given system allows an equivalent representation in the cyclic feedback form, some continuation theorems can be reformulated in a very effective fashion, thus avoiding some additional technical conditions. Applications are given again to \( \phi \)-Laplacian differential systems of the form (1.6) and our contribution Theorem 4.4 is precisely Manásevich-Mawhin theorem [16, Theorem 4.1] (without extra assumptions on the \( \phi \)-operator). Next, in Section 5 we reconsider for a broader class of differential operators Hartman-Knobloch theorem, recently extended by Mawhin in [24] and by Mawhin and Ureña in [28] to \( p \)-Laplacian systems. Finally, in Section 6 we briefly discuss some possible extensions to operators which are not defined on the whole space.

We conclude this introductory section presenting a few notation used in the present paper. In the \( N \)-dimensional real Euclidean space \( \mathbb{R}^N \) we denote by \( \langle \cdot, \cdot \rangle \) the standard inner product and by \( \| \cdot \|_{\mathbb{R}^N} \) the corresponding norm. When no confusion may occur we shall also use the symbol \( | \cdot | \) as a simplified notation for the norm. If we consider a homeomorphism \( \phi: \mathcal{A} \to \mathcal{B} \), we always implicitly assume that \( \phi(\mathcal{A}) = \mathcal{B} \). Thus, in particular, for a homeomorphism
\( \phi : \mathbb{R}^N \to \mathbb{R}^N \), we suppose that \( \phi(\mathbb{R}^N) = \mathbb{R}^N \). In any fixed (finite or infinite dimensional) normed space, we denote by \( B(x_0,r) \) (respectively, \( B[x_0,r] \)) the open (respectively, closed) ball of center a point \( x_0 \) and radius \( r > 0 \). We denote by “deg_B” the finite-dimensional Brouwer degree and by “deg_{LS}” the Leray-Schauder degree in the context of locally compact operators on arbitrary open not necessarily bounded sets (cf. [29, 30] for a precise definition). Finally, we denote by “\( DL \)” the coincidence degree extended to locally compact operators (cf. [8, Appendix A]).

2 Coincidence degree theory in product spaces

Throughout the section, when not otherwise specified, \( i \) is a generic index from 1 to \( n \).

For \( i = 1, \ldots, n \), let \( X_i, Z_i \) be real normed linear spaces and let

\[
L_i : \text{dom} \ L_i(\subseteq X_i) \to Z_i
\]

be a linear Fredholm mapping of index zero, i.e. \( \text{Im} \ L_i \) is a closed subspace of \( Z_i \) and \( \dim(\ker L_i) = \text{codim}(\text{Im} L_i) \) are finite. We denote by \( \ker L_i = L_i^{-1}(0) \subseteq X_i \) the kernel of \( L_i \), by \( \text{Im} L_i \subseteq Z_i \) the image of \( L_i \) and by \( \text{coker} L_i = Z_i/\text{Im} L_i \) the quotient space of \( Z_i \) under the equivalence relation \( w_1 \sim w_2 \) if and only if \( w_1 - w_2 \in \text{Im} L_i \). Thus \( \text{coker} L_i \) is a complementary subspace of \( \text{Im} L_i \) in \( Z_i \).

From basic results of linear functional analysis, due to the fact that \( L_i \) is a Fredholm mapping, there exist linear continuous projections

\[
P_i : X_i \to \ker L_i, \quad Q_i : Z_i \to \text{coker} L_i
\]

so that

\[
X_i = \ker L_i \oplus \ker P_i, \quad Z_i = \text{Im} L_i \oplus \text{Im} Q_i.
\]

We denote by

\[
K_i : \text{Im} L_i \to \text{dom} L_i \cap \ker P_i
\]

the right inverse of \( L_i \), i.e. \( L_i K_i(v) = v \) for each \( v \in \text{Im} L_i \). Since \( \ker L_i \) and \( \text{coker} L_i \) are finite-dimensional vector spaces of the same dimension, once an orientation on both spaces is fixed, we choose a linear orientation-preserving isomorphism \( J_i : \text{coker} L_i \to \ker L_i \).

Let us consider the product spaces

\[
X := \prod_{i=1}^n X_i, \quad Z := \prod_{i=1}^n Z_i,
\]

with the usual norms.

Setting \( \text{dom} L := \prod_{i=1}^n \text{dom} L_i \), we define \( L : \text{dom} L(\subseteq X) \to Z \) as

\[
L(u) := (L_1(u_1), \ldots, L_n(u_n)), \quad u = (u_1, \ldots, u_n) \in \text{dom} L, \quad \text{with } u_i \in X_i.
\]

It is obvious to verify that \( L \) is a linear Fredholm mapping of index zero. Next, we observe that

\[
\ker L = L_i^{-1}(0) = \prod_{i=1}^n \ker L_i \subseteq X \quad \text{and} \quad \text{Im} L = \prod_{i=1}^n \text{Im} L_i \subseteq Z
\]
are the kernel of \( L \) and the image of \( L \), respectively. Finally, we define the map 

\[ K(v) := (K_1(v_1), \ldots, K_n(v_n)), \quad v = (v_1, \ldots, v_n) \in \text{Im} \, L, \quad \text{with} \ v_i \in Z_i. \]

It is easy to check that \( K \) is the right inverse of \( L \).

Let also define \( P: X \to \ker L, \ P(u) := (P_1(u_1), \ldots, P_n(u_n)), \) for \( u = (u_1, \ldots, u_n) \in X \) (with \( u_i \in X_i \)), \( Q: Z \to \coker L, \ Q(v) := (Q_1(v_1), \ldots, Q_n(v_n)), \) for \( v = (v_1, \ldots, v_n) \in Z \) (with \( v_i \in Z_i \)), and \( J: \coker L \to \ker L, \ J(v) := (J_1(v_1), \ldots, J_n(v_n)), \) for \( v = (v_1, \ldots, v_n) \in \coker L \) (with \( v_i \in Z_i \)).

Let 

\[ N: \text{dom} \, N(\subseteq X) \to Z \]

be a nonlinear \( L \)-completely continuous operator, namely \( N \) and \( K(Id_Z - Q)N \) are continuous, and also \( QN(B) \) and \( K(Id_Z - Q)N(B) \) are relatively compact sets, for each bounded set \( B \subseteq \text{dom} \, N \). For example, \( N \) is \( L \)-completely continuous when \( N \) is continuous, maps bounded sets to bounded sets and \( K \) is a compact linear operator.

We further define \( N_i: \text{dom} \, N \to Z_i \) as 

\[ N_i(u) := (\pi_i^Z \circ N)(u), \quad u \in \text{dom} \, N, \]

where \( \pi_i^Z: Z \to Z_i \) is the standard projection.

In the sequel, to simplify the notation, we will write \( Lu \) and \( Nu \) in place of \( L(u) \) and \( N(u) \), respectively. The same convention will be used also for other operators.

Now we consider the coincidence equation

\[ Lu = Nu, \quad u \in \text{dom} \, L \cap \text{dom} \, N, \]

which can be equivalently written as a system

\[
\begin{aligned}
L_i u_i &= N_i(u_1, \ldots, u_n), \quad u = (u_1, \ldots, u_n) \in \text{dom} \, L \cap \text{dom} \, N, \\
i &= 1, \ldots, n.
\end{aligned}
\]  

(2.1)

From Mawhin’s coincidence degree theory, one can see that system (2.1) is equivalent to the fixed point problem

\[ u = \Phi(u), \quad u \in \text{dom} \, N, \]

where \( \Phi = \Phi_N: \text{dom} \, N \to X \) is defined as 

\[ \Phi(u) := Pu + JQUu + K(Id_Z - Q)Nu, \quad u \in \text{dom} \, N. \]  

(2.2)

Hence \( \Phi \) is of the form \( \Phi = (\Phi_1, \ldots, \Phi_n) \), with \( \Phi_i: \text{dom} \, N \to X_i \) given by

\[ \Phi_i(u) := P_i u_i + J_i Q_i N_i u + K_i(Id_{Z_i} - Q_i)N_i u, \quad u = (u_1, \ldots, u_n) \in \text{dom} \, N. \]

Notice that, under the above assumptions, \( \Phi: \text{dom} \, N \to X \) is a completely continuous operator.

As a first step, we state the classical homotopic invariance property of Mawhin’s coincidence degree. We present the theory in a slightly simplified version than the more general one developed in [29, 30] for locally compact operators (see Remark 5.1 for a more general statement).

We recall that the coincidence degree \( D_L(L - N, \Omega) \) of \( L \) and \( N \) in \( \Omega \) is defined as \( \text{deg}_{L,S}(Id_X - \Phi, \Omega, 0) \), for \( \Phi = \Phi_N \) as in (2.2).
Lemma 2.1 (Homotopic invariance). Let $L$ and $N$ be as above and let $\Omega \subseteq \text{dom} \ N$ be an open (possibly unbounded) set. Suppose that there exists an $L$-completely continuous map $\tilde{N} : \Omega \times [0,1] \to Z$ such that

$$\tilde{N}(u,0) = \tilde{N}(u), \quad \tilde{N}(u,1) = N(u), \quad \forall \ u \in \Omega,$$

where $\tilde{N} : \Omega \to Z$. Moreover, suppose that the set

$$S := \bigcup_{\vartheta \in [0,1]} \{ u \in \Omega \cap \text{dom} \ L : Lu = \tilde{N}(u,\vartheta) \}$$

is a compact subset of $\Omega$. Then, the map

$$\vartheta \mapsto D_{L}(L - \tilde{N}(\cdot,\vartheta),\Omega)$$

is well-defined and constant on $[0,1]$. In particular, it holds that

$$D_{L}(L - N,\Omega) = D_{L}(L - \tilde{N},\Omega).$$

Remark 2.1. In Lemma 2.1 we have stated the homotopy invariance for an $L$-completely continuous map $\tilde{N}$. We stress that the same conclusion holds for a continuous map $\tilde{N}$ such that the set $S$ is compact and there exists a bounded open neighborhood $W$ of $S$ such that $W \subseteq \Omega$ and $(K(Id_{Z} - Q)\tilde{N})|_{[0,1] \times W}$ is a compact map.

Let $\pi_{i}^{X} : X \to X_{i}$ be the standard projection. If $\Omega \subseteq X$, we define

$$\Omega_{i} := \pi_{i}^{X}(\Omega).$$

We observe that, if $\Omega$ is open in $X$, then $\Omega_{i}$ is open in $X_{i}$, for all $i = 1, \ldots, n$.

Now we recall the Reduction Formula of the Leray-Schauder degree for locally compact operators, which is a direct consequence of the Commutativity property (cf. [29, pp. 26–27] and [30, pp. 148–149]). This property will be crucial in the proof of a subsequent result (cf. Lemma 2.3).

Lemma 2.2 (Reduction Formula). Let $X$ be a normed linear space. Let $U \subseteq X$ be an open (possibly unbounded) set. Let $\Psi : U \to X$ be a continuous map such that $\deg_{LS}(Id_{X} - \Psi, U, 0)$ is defined. Let $Y \subseteq X$ be a subspace such that $\Psi(U) \subseteq Y$. Then

$$\deg_{LS}(Id_{X} - \Psi, U, 0) = \deg_{LS}(Id_{Y} - \Psi|_{Y}, U \cap Y, 0).$$

In the statement, we implicitly identify $\Psi$ with $j \circ \Psi$, where $j : Y \to X$ is the (continuous) inclusion.

The following result is an application of Lemma 2.2.

Lemma 2.3. Let $\Omega \subseteq X$ be an open (possibly unbounded) set. Let $L$ be as above and $\tilde{N} : \Omega \to Z$ be an $L$-completely continuous operator. Suppose that $\tilde{N}u, u = (u_{1}, \ldots, u_{n}) \in \Omega$, has components of the following form

$$\begin{cases} \tilde{N}_{i}(u_{i+1}), & \text{for } i = 1, \ldots, n-1; \\ \tilde{N}_{n}(u_{1}, \ldots, u_{n}). & \end{cases}$$
Assume that
\[ \text{Im } L_i \cap \tilde{N}_i (\Omega_{i+1} \cap \ker L_{i+1}) \subseteq \{0_{Z_i}\}, \quad \text{for all } i = 1, \ldots, n-1, \quad (2.3) \]
and
\[ \text{Im } L_n \cap \tilde{N}_n (\Omega \cap \text{dom } L) \subseteq \{0_{Z_n}\}. \quad (2.4) \]
Moreover, assume that
\[ \{ u \in \Omega \cap \ker L : \tilde{N} u = 0_{Z} \} \]
is a compact subset of \( \Omega \). Then
\[ D_L (L - \tilde{N}, \Omega) = \deg_B (\tilde{N}, \Omega \cap \ker L, 0), \]
where \( \tilde{N} : \Omega \cap \ker L \to \ker L \) is defined as
\[ \tilde{N} := (-J_1 Q_1 \tilde{N}_1 |_{\text{ker } L_2} \cdots J_{n-1} Q_{n-1} \tilde{N}_{n-1} |_{\text{ker } L_n}) J_n \tilde{N}_n |_{\text{ker } L}. \]

Proof. First of all, we introduce the operator \( \tilde{\Phi} : [0,1] \times \Omega \to X \) of the form
\[ \tilde{\Phi} (\vartheta, u) = \Phi^\vartheta (u) = (\tilde{\Phi}_1^\vartheta(u), \ldots, \tilde{\Phi}_n^\vartheta(u)), \]
with \( \tilde{\Phi}_i^\vartheta : \Omega \to X_i \) defined as
\[ \begin{cases} \tilde{\Phi}_i^\vartheta (u) := P_i u_i + J_i Q_i \tilde{N}_i u_{i+1} + \vartheta K_i (Id_{Z_i} - Q_i) \tilde{N}_i u_{i+1}, & i = 1, \ldots, n-1; \\ \tilde{\Phi}_n^\vartheta (u) := P_n u_n + J_n Q_n \tilde{N}_n u + \vartheta K_n (Id_{Z_n} - Q_n) \tilde{N}_n u. \end{cases} \]

We stress that \( \tilde{\Phi} \) is the completely continuous operator associated with the coincidence equation
\[ L u = \vartheta \tilde{N} u, \quad u \in \Omega \cap \text{dom } L, \quad \vartheta \in [0,1], \]
in the sense that \( u \in \Omega \) is such that \( u = \tilde{\Phi}^\vartheta (u) \) for some \( \vartheta \in [0,1] \) if and only if \( u \in \Omega \cap \text{dom } L \) and \( L u = \vartheta \tilde{N} u \).

We claim that the set
\[ \mathcal{S} := \bigcup_{\vartheta \in [0,1]} \{ u \in \Omega : u = \tilde{\Phi}^\vartheta (u) \} \]
is a compact subset of \( \Omega \).

Let us fix an arbitrary \( \vartheta \in [0,1] \). If \( u \in \Omega \) is such that \( u = \tilde{\Phi}^\vartheta (u) \), then, in particular, from the last equation it holds that
\[ u_n = P_n u_n + J_n Q_n \tilde{N}_n u + \vartheta K_n (Id_{Z_n} - Q_n) \tilde{N}_n u, \]
so that
\[ u \in \Omega \cap \text{dom } L \quad (u_n \in \Omega_n \cap \text{dom } L_n) \quad \text{and} \quad L_n \frac{u_n}{\vartheta} = \tilde{N}_n u. \]

From hypothesis (2.4), we easily obtain that
\[ u_n \in \Omega_n \cap \ker L_n \quad \text{and} \quad \tilde{N}_n u = 0_{Z_n}. \]
Next, considering the \((n-1)\)-component of the equality \( u = \tilde{\Phi}^\vartheta (u) \), we can write
\[ u_{n-1} = P_{n-1} u_{n-1} + J_{n-1} Q_{n-1} \tilde{N}_{n-1} u_n + \vartheta K_{n-1} (Id_{Z_{n-1}} - Q_{n-1}) \tilde{N}_{n-1} u_n, \]
10
so that

\[ u_{n-1} \in \Omega_{n-1} \cap \text{dom } L_{n-1} \quad \text{and} \quad L_{n-1} \frac{u_{n-1}}{\vartheta} = \hat{N}_{n-1} u_n. \]

Taking into account that \( u_n \in \Omega_n \cap \ker L_n \), hypothesis \((2.3)\) (with \( i = n-1 \)) ensures that

\[ u_{n-1} \in \Omega_{n-1} \cap \ker L_{n-1} \quad \text{and} \quad \hat{N}_{n-1} u_n = 0_{Z_{n-1}}. \]

Proceeding in this way (by repeating inductively the same argument), hypothesis \((2.3)\) ensures that

\[ u_i \in \Omega_i \cap \ker L_i \quad \text{and} \quad \hat{N}_i u_i = 0_{Z_i}, \quad \text{for all } i = 1, \ldots, n-1. \]

Next, let \( \vartheta = 0 \). If \( u \in \Omega \) is such that \( u = \tilde{\Phi}^0(u) \), then

\[
\begin{cases}
u_i = P_i u_i + J_i Q_i \hat{N}_i u_{i+1}, & i = 1, \ldots, n-1; \\
u_n = P_n u_n + J_n Q_n \hat{N}_n u.
\end{cases}
\]

We immediately deduce that

\[ u_i \in \Omega_i \cap \ker L_i \quad \text{for all } i = 1, \ldots, n, \]

and so \( u_i = P_i u_i \). Therefore, \( Q_i \hat{N}_i u_{i+1} = 0_{Z_i} \), for \( i = 1, \ldots, n-1 \), and \( Q_n \hat{N}_n u = 0_{Z_n} \). Then, \( \hat{N}_i u_{i+1} \in \text{Im } L_i \), for \( i = 1, \ldots, n-1 \), and \( \hat{N}_n u \in \text{Im } L_n \). Hence, we obtain that

\[ \hat{N}_i u_{i+1} \in \text{Im } L_i \cap \hat{N}_i (\Omega_{i+1} \cap \ker L_{i+1}) = \{0_{Z_i}\}, \quad \text{for all } i = 1, \ldots, n-1; \]

and

\[ \hat{N}_n u \in \text{Im } L_n \cap \hat{N}_n (\Omega \cap \text{dom } L) = \{0_{Z_n}\}. \]

Then

\[ \hat{N} u = 0_{\Omega}. \]

By the above observations, we have that \( \hat{S} \subseteq \{ u \in \Omega \cap \ker L : \hat{N} u = 0_{\Omega} \} \).

Since the converse inclusion is trivial, we obtain that

\[ \hat{S} = \{ u \in \Omega \cap \ker L : \hat{N} u = 0_{\Omega} \}. \]

Therefore, by the hypothesis, \( \hat{S} \) is a compact subset of \( \Omega \).

The homotopy invariance of the Leray-Schauder degree for locally compact operators implies that the map

\[ \vartheta \mapsto \deg_{LS}(Id_X - \tilde{\Phi}^0, \Omega, 0) \]

is well-defined and constant on \([0, 1]\). In particular, it holds that

\[ D_L(L - \hat{N}, \Omega) = \deg_{LS}(Id_X - \tilde{\Phi}^0, \Omega, 0) = \deg_{LS}(Id_X - \Phi^0, \Omega, 0), \]

where

\[ \tilde{\Phi}^0 = P u + J Q \hat{N} : \Omega \to \ker L. \]

Finally, we notice that \( \Phi^0(\Omega) \subseteq \ker L \) and recall that \( \ker L \) is a finite-dimensional subspace of \( X \). Therefore, we can apply the Reduction Formula (i.e. Lemma 2.2) with \( U = \Omega, \Psi = \tilde{\Phi}^0 \) and \( Y = \ker L \) and we conclude that

\[ \deg_{LS}(Id_X - \tilde{\Phi}^0, \Omega, 0) = \deg_{LS}(Id_{\ker L} - \Phi^0|_{\ker L}, \Omega \cap \ker L, 0) = \deg_{LS}(\hat{N}, \Omega \cap \ker L, 0). \]

The thesis immediately follows. \( \square \)
Remark 2.2. We underline that the same conclusion of Lemma 2.3 holds if in the statement we replace conditions \((2.3)\) and \((2.4)\) with
\[\hat{N}_i(\Omega_{i+1} \cap \ker L_{i+1}) \subseteq \text{coker } L_i, \text{ for all } i = 1, \ldots, n-1,\]
and
\[\hat{N}_n(\Omega) \subseteq \text{coker } L_n,\]
respectively.

Combining Lemma 2.1 and Lemma 2.3, we obtain the following result.

Theorem 2.1. Let \(L\) be as above and let \(M: \text{dom } M(\subseteq X) \to Z\) be a non-linear \(L\)-completely continuous operator. Suppose that \(Mu, \ u = (u_1, \ldots, u_n) \in \text{dom } M\), has components of the following form
\[
\begin{cases}
M_i(u_{i+1}), & \text{for } i = 1, \ldots, n-1; \\
M_n(u_1, \ldots, u_n).
\end{cases}
\]
For \(\vartheta \in [0,1]\), consider the following coincidence system
\[
(P_\vartheta) \quad \begin{cases}
L_i u_i = M_i(u_{i+1}), & i = 1, \ldots, n-1; \\
L_n u_n = \vartheta M_n(u_1, \ldots, u_n).
\end{cases}
\]
Let \(\Omega \subseteq \text{dom } M\) be an open (possibly unbounded) set. We define
\[S_\vartheta := \{u \in \Omega \cap \text{dom } L: \ u \text{ is a solution of } (P_\vartheta)\}, \ \vartheta \in [0,1].\]
Assume that
(i) \(\text{Im } L_i \cap M_i(\Omega_{i+1} \cap \ker L_{i+1}) \subseteq \{0_Z\}, \text{ for all } i = 1, \ldots, n-1;\)
(ii) there exists a compact set \(K \subseteq \Omega\) such that \(S_\vartheta \subseteq K, \text{ for all } \vartheta \in [0,1];\)
(iii) the set \(S_0 := \{u \in \Omega \cap \ker L: QMu = 0\}\) is compact.

Then
\[D_L(L - M, \Omega) = \deg_{B}(\mathcal{M}, \Omega \cap \ker L, 0),\]
where \(\mathcal{M}: \Omega \cap \ker L \to \ker L\) is defined as
\[\mathcal{M} := (-J_1Q_1M_1|_{\Omega_{2} \cap \ker L_2}, \ldots, -J_{n-1}Q_{n-1}M_{n-1}|_{\Omega_n \cap \ker L_n}, -J_nQ_nM_n|_{\Omega \cap \ker L}).\]

Proof. For \(\vartheta \in [0,1]\), we define the auxiliary coincidence system
\[
(\mathcal{A}_\vartheta) \quad \begin{cases}
L_i u_i = M_i(u_{i+1}), & i = 1, \ldots, n-1; \\
L_n u_n = \vartheta M_n u + (1 - \vartheta)Q_n M_n u
\end{cases}
\]
and the set
\[S'_\vartheta := \{u \in \Omega \cap \text{dom } L: \ u \text{ is a solution of } (\mathcal{A}_\vartheta)\}.\]
First of all, we observe that
\[S'_\vartheta = S_\vartheta, \text{ for all } \vartheta \in [0,1],\]
namely $u$ is a solution of $(\mathcal{A}_\vartheta)$ if and only if $u$ is a solution of $(\mathcal{P}_\vartheta)$. Indeed, if $u$ is a solution of $(\mathcal{A}_\vartheta)$, applying the projection $Q_n$ to the last equation of $(\mathcal{A}_\vartheta)$, we obtain $Q_n M_n u = 0$; then clearly $u$ solves $(\mathcal{P}_\vartheta)$. On the other hand, if $u$ is a solution of $(\mathcal{P}_\vartheta)$, applying the projection $Q_n$ to the last equation of $(\mathcal{P}_\vartheta)$, we obtain $\vartheta Q_n M_n u = 0$ (with $\vartheta \neq 0$); then we deduce that $u$ solves $(\mathcal{A}_\vartheta)$. Secondly, we notice that $S'_\vartheta \subseteq S_0$. (2.5)

Indeed, if $u$ is a solution of $(\mathcal{A}_0)$, then $L_n u_n = Q_n M_n u$. Hence, $u_n \in \ker L_n$ and $Q_n M_n u = 0$. Therefore, using condition $(i)$, we find that $u \in \ker L$ and also $Q M u = 0$. In this manner (2.5) is proved.

Let $\tilde{M}: \Omega \times [0, 1] \rightarrow Z$ be the continuous homotopy with components

$$\left\{ \begin{array}{ll} M_i(u_{i+1}), & \text{for } i = 1, \ldots, n - 1; \\ \vartheta M_n u + (1 - \vartheta)Q_n M_n u, & \end{array} \right.$$ 

where $u = (u_1, \ldots, u_n) \in \Omega$ and $\vartheta \in [0, 1]$. We observe that $\tilde{M}(u, 1) = Mu$ and $\tilde{M}(u, 0)$ has $Q_n M_n u$ as last component (which is finite-dimensional).

We divide the proof into two steps.

**Step 1.** We claim that

$$D_L(L - M, \Omega) = D_L(L - \tilde{M}(\cdot, 0), \Omega).$$

We first notice that, from condition $(ii)$ and the above remark, we have $S'_\vartheta \subseteq K$, for all $\vartheta \in [0, 1]$. Recalling also (2.5) together with condition $(iii)$, we find that

$$\bigcup_{\vartheta \in [0, 1]} \{ u \in \Omega \cap \text{dom } L: Lu = \tilde{M}(u, \vartheta) \} = \bigcup_{\vartheta \in [0, 1]} S'_\vartheta$$

is a compact subset of $\Omega$, since closed and contained in the compact set $K \cup S_0$. Therefore we can apply Lemma 2.1. The claim is thus proved.

**Step 2.** We claim that

$$D_L(L - \tilde{M}(\cdot, 0), \Omega) = \deg_B(M, \Omega \cap \ker L, 0).$$

We are going to apply Lemma 2.3 to the $L$-completely continuous operator $\hat{N}: \Omega \rightarrow Z$ defined in this way: the components of $\hat{N} u$, $u = (u_1, \ldots, u_n) \in \Omega$, have the following form

$$\left\{ \begin{array}{ll} \hat{N}_i(u_{i+1}), & \text{for } i = 1, \ldots, n - 1; \\ \hat{N}_n(u_1, \ldots, u_n) := Q_n M_n (u_1, \ldots, u_n). & \end{array} \right.$$ 

Clearly condition (2.3) of Lemma 2.3 corresponds to condition $(i)$. Moreover, hypothesis (2.4) is satisfied, since by the definition of $\hat{N}_n$ it holds that $\hat{N}_n(\Omega) \subseteq \text{coker } L_n$ (see also Remark 2.2). Next, we observe that the set \{ $u \in \Omega \cap \ker L: Mu = 0$ \} is a compact subset of $\Omega$, since it is closed and contained in the compact set $\{ u \in \Omega \cap \ker L: QM u = 0 \} = S_0$ (by condition $(iii)$). Finally, applying Lemma 2.3 the claim follows.

From **Step 1** and **Step 2** the proof of the theorem is concluded. 

\[ \square \]
Remark 2.3. In Theorem 2.1 we define an homotopy $\tilde{M}(u, \vartheta)$ transforming only the last equation of the systems. We underline that the same result is valid considering homotopies of the form
\[
\begin{align*}
M_i(u_{i+1}) & \quad \text{for } i = 1, \ldots, k - 1; \\
\partial M_i(u_1, \ldots, u_n) & \quad \text{for } i = k, \ldots, n.
\end{align*}
\]
Anyway, in our presentation we prefer to state the results as in Theorem 2.1 in order to present a version which is suitable for the application in Section 3.

The classical Mawhin’s continuation theorem (cf. [20, Proposition 2.1]) deals with an open and bounded set $\Omega$ such that for each $\lambda \in ]0, 1[$ the equation $Lu = \lambda Nu$ has no solutions in $\partial \Omega$ and, moreover,
\[
\deg_B(-JQ_i|_{\Omega \cap \ker L}, \Omega \cap \ker L, 0) \neq 0.
\]
Under these assumptions, there exists a solution $u \in \Omega$ to the coincidence equation $Lu = Nu$. Clearly, in the same situation (i.e. when $\Omega$ is open and bounded), we could state an analogous existence result for system
\[
(P_1)
\]
using Theorem 2.1 via the homotopy described in $(P_{\vartheta})$. In such a case, we should suppose, instead of (2.6), that
\[
\deg_B(M, \Omega \cap \ker L, 0) \neq 0\tag{2.7}
\]
holds (where $M$ is defined as in Theorem 2.1).

Actually the above new existence result can be stated also for an open and possibly unbounded set $\Omega$. Precisely, assuming all the hypotheses of Theorem 2.1 and in addition that (2.7) holds, we can immediately conclude that there exists a solution $u \in \Omega$ to the coincidence system $(P_1)$.

In order to make such new existence theorems useful for the applications, we need first to provide more explicit conditions in order to evaluate the Brouwer degree associated with the map $M$. Therefore, we conclude this section with a result that allows us to compute the degree of a map having the same structure as $M$ in Theorem 2.1. To this aim, we first introduce the following notation. Keeping for the rest of the section the hypotheses of Theorem 2.1 for $i = 1, \ldots, n - 1$, let us define the maps $\eta_i : \Omega_{i+1} \cap \ker L_{i+1} \to \ker L_i$ as
\[
\eta_i(w) := -JQ_i M_i w, \quad w \in \Omega_{i+1} \cap \ker L_{i+1},
\]
and the map $\eta_n : \tilde{\Omega}_1 \to \ker L_n$ as
\[
\eta_n(w) := -J_n Q_n M_n(w, 0, \ldots, 0), \quad w \in \tilde{\Omega}_1,
\]
where $\tilde{\Omega}_1 := \{w \in \ker L_1 : (w, 0, \ldots, 0) \in \Omega\}$.

We will also assume some additional conditions which simplify the statement of the next result and which are natural for the applications presented in Section 3 and Section 4. In more detail, in Lemma 2.4 we assume this crucial hypothesis.
(h₁) $\dim(\ker L_i) = d$, for all $i = 1, \ldots, n$.

Accordingly, for $i = 1, \ldots, n$, it is not restrictive to identify $\ker L_i$ with $\mathbb{R}^d$. Consequently, condition (h₁) ensures that $\dim(\coker L_i) = d$, for all $i = 1, \ldots, n$.

Moreover, we also identify $\coker L_i$ with $\mathbb{R}^d$, for all $i = 1, \ldots, n$. Under this position, without loss of generality, for all $i = 1, \ldots, n$, we take $J_i = \text{Id}_{\mathbb{R}^d}$ as linear orientation-preserving isomorphism from $\mathbb{R}^d$ to $\mathbb{R}^d$. With this in mind, in the sequel, by an abuse of notation, we will write $-Q_i M_i$ in place of $-J_i Q_i M_i$.

Under this convention, we state the following result.

**Lemma 2.4.** Let $L$, $M$ and $\Omega$ be as in Theorem 2.1. Let $\mathcal{M}: \Omega \cap \ker L \to \ker L$ be defined as

$$\mathcal{M}(u) := (\eta_1(u_1), \ldots, \eta_{n-1}(u_n), -J_n Q_n M_n|_{\Omega \cap \ker L} u), \quad u \in \Omega \cap \ker L.$$ 

Moreover, assume that the degree $\deg_B(\mathcal{M}, \Omega \cap \ker L, 0)$ is well-defined and suppose that the following conditions hold:

(1) $\dim(\ker L_i) = d$, for all $i = 1, \ldots, n$;

(2) $0_{X_i} \in \Omega_i \cap \ker L_i$, for all $i = 2, \ldots, n$;

(3) $\{w \in \Omega_{i+1} \cap \ker L_{i+1}: \eta_i(w) = 0_{X_i}\} = \{0_{X_{i+1}}\}$, for all $i = 1, \ldots, n-1$.

Then

$$\deg_B(\mathcal{M}, \Omega \cap \ker L, 0) = (-1)^{d(n+1)} \deg_B(\eta_n, \bar{\Omega}_1, 0) \prod_{i=1}^{n-1} \deg_B(\eta_i, \Omega_{i+1} \cap \ker L_{i+1}, 0).$$

**Proof.** Let

$$\bar{\Omega} := \bar{\Omega}_1 \times (\Omega_2 \cap \ker L_2) \times \cdots \times (\Omega_n \cap \ker L_n)$$

and let $\eta: \bar{\Omega} \to \ker L$ be defined as

$$\eta(u) = (\eta_1(u_2), \ldots, \eta_{n-1}(u_n), \eta_n(u_1)), \quad u = (u_1, \ldots, u_n) \in \bar{\Omega}.$$ 

Notice that $\bar{\Omega} \subseteq \Omega \cap \ker L$.

**Step 1.** We claim that

$$\deg_B(\mathcal{M}, \Omega \cap \ker L, 0) = \deg_B(\eta, \bar{\Omega}, 0).$$

We introduce the operator $\bar{\mathcal{M}}: [0,1] \times (\Omega \cap \ker L) \to \ker L$ of the form $\bar{\mathcal{M}} = (\bar{M}_1, \ldots, \bar{M}_n)$, with $\bar{M}_i : [0,1] \times (\Omega \cap \ker L) \to \ker L_i$ defined as

$$\begin{cases}
\bar{M}_i(\vartheta, u) := \eta_i(u_{i+1}), & i = 1, \ldots, n-1; \\
\bar{M}_n(\vartheta, u) := -Q_n M_n(u_1, u_2, \ldots, u_n).
\end{cases}$$

We stress that $\bar{\mathcal{M}}$ is a completely continuous operator.

We claim that the set

$$\bar{S} := \bigcup_{\vartheta \in [0,1]} \{u \in \Omega \cap \ker L: \bar{\mathcal{M}}(\vartheta, u) = 0\}$$
is a compact subset of \( \Omega \cap \ker L \).

Let us fix an arbitrary \( \vartheta \in [0,1] \). If \( u \in \Omega \cap \ker L \) is such that \( \tilde{\mathcal{M}}(\vartheta,u) = 0 \), then
\[
\begin{cases}
\eta_i(u_{i+1}) = 0, & i = 1, \ldots, n-1; \\
-Q_n M_n(u_1, \vartheta u_2, \ldots, \vartheta u_n) = 0.
\end{cases}
\]
From the first \((n-1)\) equations and hypothesis \((h_3)\), we immediately obtain that
\[ u_i = 0_{X_i}, \quad \text{for all } i = 2, \ldots, n, \]
and hence the last equation reads as follows
\[ \eta_n(u_1) = -Q_n M_n(u_1, 0, \ldots, 0) = 0_{X_n}. \]
We conclude that
\[ S = \{ (w,0,\ldots,0) \in \Omega : w \in \ker L \} = \{ u \in \Omega \cap \ker L : \mathcal{M}u = 0 \} \]
is a compact subset of \( \Omega \cap \ker L \) (since \( \deg_B(\mathcal{M},\Omega \cap \ker L,0) \) is well-defined).

The homotopic invariance of the Brouwer degree implies that
\[ \vartheta \mapsto \deg_B(\tilde{\mathcal{M}}(\vartheta,\cdot),\Omega \cap \ker L,0) \]
is well-defined and constant on \([0,1]\). In particular, since \( S \subseteq \bar{\Omega} \), it holds that
\[ \deg_B(\mathcal{M},\Omega \cap \ker L,0) = \deg_B(\tilde{\mathcal{M}}(0,\cdot),\Omega \cap \ker L,0) = \deg_B(\eta,\bar{\Omega},0). \]

**Step 2.** Let \( \tilde{\eta} : \bar{\Omega} \to \ker L \) be defined as
\[
\tilde{\eta}(u) = (\eta_n(u_1), \eta_1(u_2), \ldots, \eta_{n-1}(u_n)), \quad u = (u_1, \ldots, u_n) \in \bar{\Omega}.
\]
Clearly
\[ \tilde{\eta}(u) = P\eta(u), \quad \forall u \in \bar{\Omega}, \]
where
\[
P = \begin{pmatrix}
0 & 0 & \cdots & 0 & I_d \\
I_d & 0 & \cdots & 0 & 0 \\
0 & \ddots & \ddots & \vdots & \vdots \\
& \ddots & I_d & 0 & 0 \\
0 & \cdots & 0 & I_d & 0
\end{pmatrix} \in \mathbb{R}^{dn \times dn}
\]
is a permutation matrix with determinant \( \det(P) = (-1)^d(n+1) \), where \( I_d := I_{d \times d} \). Therefore, using the definition of the Brouwer degree of a composition of maps, we obtain
\[
\deg_B(\tilde{\eta},\bar{\Omega},0) = \deg_B(P\eta,\bar{\Omega},0) = \sign(\det(P)) \deg_B(\eta,\bar{\Omega},0) = (-1)^d(n+1) \deg_B(\eta,\bar{\Omega},0).
\]
Now, the multiplicativity property of the Brouwer degree (cf. [3, Theorem 11.3]) gives
\[
\deg_B(\tilde{\eta},\bar{\Omega},0) = \deg_B(\eta_n,\bar{\Omega}_1,0) \cdot \prod_{i=1}^{n-1} \deg_B(\eta_i,\Omega_{i+1} \cap \ker L_{i+1},0).
\]
From Step 1 and Step 2, we have
\[
\deg_B(M, \Omega \cap \ker L, 0) = \deg_B(\eta, \Omega, 0) = \\
= (-1)^{d(n+1)} \deg_B(\eta_0, \tilde{\Omega}, 0) \cdot \prod_{i=1}^{n-1} \deg_B(\eta, \Omega_i+1 \cap \ker L_{i+1}, 0)
\]
and the lemma follows.

3 Periodic solutions to cyclic feedback systems: homotopy to the averaged nonlinearity

In this section we show an application of the theory presented in Section 2 to the $T$-periodic problem (for $T > 0$) associated with the differential system

\[
\begin{cases}
x'_1 = g_1(x_2) \\
x'_2 = g_2(x_3) \\
\vdots \\
x'_{n-1} = g_{n-1}(x_n) \\
x'_n = h(t, x_1, \ldots, x_n),
\end{cases}
\]

(\mathcal{C})

which has been considered in the introduction. Throughout this section, we assume that, for $i = 1, \ldots, n-1$, the maps $g_i: \mathbb{R}^m \to \mathbb{R}^m$ are continuous and $h: [0, T] \times \mathbb{R}^m \times \cdots \times \mathbb{R}^m \to \mathbb{R}^m$ is an $L^1$-Carathéodory function. A $T$-periodic solution of (\mathcal{C}) is a vector function $x = (x_1, \ldots, x_n)$ such that, for every $i = 1, \ldots, n$, $x_i: [0, T] \to \mathbb{R}^m$ is an absolutely continuous function such that $x_i(0) = x_i(T)$ and moreover $x(t)$ satisfies (\mathcal{C}) for a.e. $t \in [0, T]$. It is a well-known fact that, if we suppose that $\mathbb{R} \ni t \mapsto h(t, s_1, \ldots, s_n)$ is a $T$-periodic map, then any $T$-periodic solution according to our definition can be extended to the whole real line to an absolutely continuous solution of (\mathcal{C}) such that $x(t+T) = x(t)$ for all $t \in \mathbb{R}$.

Remark 3.1. In order to simplify our presentation, we have confined ourselves to the case in which the right-hand side of system (\mathcal{C}) is defined on the whole space $\mathbb{R}^{mn}$. However, the abstract results in Section 2 are suited to be applied also to the case in which one or more components of the vector field in (\mathcal{C}) are defined only on some open subsets of the involved Euclidean spaces. In particular, we will state Lemma 3.1 and the subsequent results by assuming $\Omega \subseteq \text{dom} \ M$, where $M$ will be the Nemytskii operator associated to the right-hand side of (\mathcal{C}), so that they are applicable to the most general situation. Clearly, in our simplified setting the hypothesis $\Omega \subseteq \text{dom} \ M$ will be equivalent to consider as $\Omega$ just an open subset of $C([0, T], \mathbb{R}^{mn})$.

\[\triangleleft\]

In order to enter the setting presented in Section 2 and to write the system in the form

\[Lx = Mx, \quad x \in \text{dom} \ L \cap \text{dom} \ M,\]

we will adapt to our situation the classical treatment in [21]. For $i = 1, \ldots, n$, let $X_i := C([0, T], \mathbb{R}^m)$ be the space of continuous functions $x_i: [0, T] \to \mathbb{R}^m$, etc.
endowed with the sup-norm
\[ \|x_i\|_\infty := \max_{t \in [0, T]} |x_i(t)|, \]
and let \( Z_i := L^1([0, T], \mathbb{R}^m) \) be the space of integrable functions \( z_i : [0, T] \rightarrow \mathbb{R}^m \), endowed with the norm
\[ \|z_i\|_{L^1} := \int_0^T |z_i(t)| \, dt. \]
In this manner, we have \( X = C([0, T], \mathbb{R}^{mn}) \) and \( Z = L^1([0, T], \mathbb{R}^{mn}) \) (with the standard norms).

For \( i = 1, \ldots, n \), we consider the linear differential operator \( L_i : \text{dom} \, L_i \rightarrow Z_i \) defined as
\[ (L_i x_i)(t) := x_i'(t), \quad t \in [0, T], \]
where \( \text{dom} \, L_i \) is determined by the functions of \( X_i \) which are absolutely continuous and satisfy the periodic boundary condition
\[ x_i(0) = x_i(T). \tag{3.1} \]

Therefore, \( L_i \) is a Fredholm map of index zero, \( \ker L_i \) and \( \text{coker} L_i \) are made up of the constant functions in \( \mathbb{R}^m \) and
\[ \text{Im} \, L_i = \left\{ z_i \in Z_i : \int_0^T z_i(t) \, dt = 0 \right\}. \]
As projectors \( P_i : X_i \rightarrow \ker L_i \) and \( Q_i : Z_i \rightarrow \text{coker} L_i \) associated with \( L_i \), for \( i = 1, \ldots, n \), we choose the average operators
\[ P_i x_i = Q_i x_i := \frac{1}{T} \int_0^T x_i(t) \, dt. \]
Notice that \( \ker P_i \) is given by the continuous functions with mean value zero. Next, let \( K_i : \text{Im} \, L_i \rightarrow \text{dom} \, L_i \cap \ker P_i \) be the right inverse of \( L_i \), which is the operator that to any function \( z_i \in Z_i \) with \( \int_0^T z_i(t) \, dt = 0 \) associates the unique solution \( x_i(t) \) of
\[ x_i'(t) = z_i(t), \quad \text{with} \quad \int_0^T x_i(t) \, dt = 0, \]
which clearly satisfies the boundary condition \( x_i(0) = x_i(T) \). Finally, we take the identity map in \( \mathbb{R}^m \) as linear orientation-preserving isomorphism \( J_i : \text{coker} L_i \rightarrow \ker L_i \).

Now we consider as nonlinear operator \( M : \text{dom} \, M = X \rightarrow Z \) the Nemytskii operator induced by the functions \( g_i \) and \( h \), namely the operator \( M \) has the following components
\[
\begin{aligned}
M_i(x_{i+1})(t) &:= g_i(x_{i+1}(t)), \\
M_n(x_1, \ldots, x_n)(t) &:= h(t, x_1(t), \ldots, x_n(t)),
\end{aligned}
\]
where \( x = (x_1, \ldots, x_n) \in \text{dom} \, M \) and \( t \in [0, T] \). From the above hypotheses it follows that \( M \) is an \( L \)-completely continuous operator.
Finally, we introduce the averaged vector field $h^\#: \mathbb{R}^m \rightarrow \mathbb{R}^m$ defined by

$$h^\#(s) := \frac{1}{T} \int_0^T h(t, s_1, \ldots, s_n) \, dt, \quad s = (s_1, \ldots, s_n) \in \mathbb{R}^{mn}.$$ 

We also define $\hat{g}: \mathbb{R}^m \rightarrow \mathbb{R}^m$ as

$$\hat{g}(s) := (g_1(s_2), \ldots, g_{n-1}(s_n), h^\#(s)), \quad s = (s_1, \ldots, s_n) \in \mathbb{R}^{mn}.$$ 

Note that, according to the above positions, it turns out that $\hat{g} = JQM|_{ker L}$.

We are now in position to state our first result, which is a direct consequence of Theorem 2.1.

**Lemma 3.1.** Let $\Omega \subseteq \text{dom } M$ be an open (possibly unbounded) set. Suppose that the following conditions hold.

\[ (c_1) \text{ There exists a compact set } K \subseteq \Omega \text{ containing all the possible } T\text{-periodic solutions of} \]

\[ \begin{align*}
    x'_1 &= g_1(x_2) \\
    x'_2 &= g_2(x_3) \\
    & \vdots \\
    x'_{n-1} &= g_{n-1}(x_n) \\
    x'_n &= \vartheta h(t, x_1, \ldots, x_n),
\end{align*} \]

for any $\vartheta \in ]0,1[$. 

\[ (c_2) \text{ The set } \hat{g}^{-1}(0) \cap \Omega \text{ is compact.} \]

Then

$$D_L(L - M, \Omega) = (-1)^{mn} \deg_B(\hat{g}, \Omega \cap \mathbb{R}^{mn}, 0).$$

**Proof.** According to the above positions, we have

$$-J_iQ_iM_i(s_{i+1}) = -g_i(s_{i+1}), \quad \forall s_{i+1} \in \Omega_{i+1} \cap \ker L_{i+1}, \quad \forall i = 1, \ldots, n - 1,$$

and

$$-J_nQ_n M_n(s) = -h^\#(s), \quad \forall s \in \Omega \cap \ker L.$$ 

In order to apply Theorem 2.1, we have to verify that hypotheses (i), (ii) and (iii) of that theorem are satisfied. Clearly (i) holds, since the only constant function with zero mean value is the null function. On the other hand, (ii) and (iii) are direct consequences of $(c_1)$ and $(c_2)$, respectively, in the functional analytic setting that we have introduced at the beginning of the section. Then

$$D_L(L - M, \Omega) = \deg_B(-\hat{g}, \Omega \cap \mathbb{R}^{mn}, 0)$$

and thus the conclusion follows. \qed

From Lemma 3.1 we immediately obtain the following existence result. The obvious proof is omitted.
**Theorem 3.1.** Let $\Omega \subseteq \text{dom } M$ be an open (possibly unbounded) set. Suppose that $(c_1)$ and $(c_2)$ hold. If

\[ \deg_B(\hat{g}, \Omega \cap \mathbb{R}^{mn}, 0) \neq 0, \]

then there exists at least a $T$-periodic solution of (C) in $\Omega$.

Theorem 3.1 relies on the evaluation of the Brouwer degree of $\hat{g}$. We show now how to compute this degree in terms of that relative to $h^\#$, via Lemma [2.4]. To this end, given an open set $\Omega \subseteq \text{dom } M$ we recall the definition of $\Omega_i := \pi_i X(\Omega)$. We also set

\[ O_1 := \{ \omega \in \mathbb{R}^m : (\omega, 0, \ldots, 0) \in \Omega \} \]

(which corresponds to the set $\tilde{\Omega}_1$ of Lemma [2.4]) and

\[ O_i := \Omega_i \cap \mathbb{R}^m, \text{ for } i = 2, \ldots, n. \]

Finally, we introduce the map $h^* : \mathbb{R}^m \to \mathbb{R}^m$

\[ h^*(\omega) := h^#(\omega, 0, \ldots, 0), \quad \omega \in \mathbb{R}^m. \]

Then, we have the following result.

**Proposition 3.1.** Let $\Omega \subseteq \text{dom } M$ be an open (possibly unbounded) set. Suppose that

$(c_3)$ $0 \in O_i$, for each $i = 2, \ldots, n$;

$(c_4)$ $g_i(0) = 0$, for each $i = 1, \ldots, n - 1$;

$(c_5)$ $g_i(\omega) \neq 0$ for every $\omega \in O_{i+1} \setminus \{0\}$, for each $i = 1, \ldots, n - 1$;

$(c_6)$ the set $(h^*)^{-1}(0) \cap O_1$ is compact.

Then, $\deg_B(\hat{g}, \Omega \cap \mathbb{R}^{mn}, 0)$ is well-defined and the following formula holds

\[ \deg_B(\hat{g}, \Omega \cap \mathbb{R}^{mn}, 0) = (-1)^{m(n+1)} \deg_B(h^*, O_1, 0) \cdot \prod_{i=1}^{n-1} \deg_B(g_i, O_{i+1}, 0). \]

**Proof.** As a first step, we observe that $\deg_B(\hat{g}, \Omega \cap \mathbb{R}^{mn}, 0)$ is well-defined if condition $(c_2)$ holds. Now, using $(c_3)$, $(c_4)$ and $(c_5)$, we immediately deduce

\[ \hat{g}^{-1}(0) \cap \Omega = \{ (\omega, 0, \ldots, 0) \in \Omega \cap \mathbb{R}^{mn} : \omega \in (h^*)^{-1}(0) \}. \]

Hence $(c_2)$ is valid if and only if $(c_6)$ is satisfied.

As a second step, we assume that $\deg_B(\hat{g}, \Omega \cap \mathbb{R}^{mn}, 0)$ is well-defined. Using the above positions, it is straightforward to check that the assumptions of Lemma [2.4] are satisfied with dimension $d = m$ in $(h_1)$, $(h_2)$ and $(h_3)$ following from $(c_3)$ and from $(c_4)$, $(c_5)$, respectively. \qed

From now on, in the next results, we will assume all the hypotheses of Proposition 3.1. In this manner, condition $(c_6)$ will ensure that both the degrees $\deg_B(\hat{g}, \Omega \cap \mathbb{R}^{mn}, 0)$ and $\deg_B(h^*, O_1, 0)$ are well-defined.

Combining Theorem 3.1 and Proposition 3.1, we obtain the following.
Corollary 3.1. Let \( \Omega \subseteq \text{dom} \, M \) be an open (possibly unbounded) set. Assume \((c_1), (c_3), (c_4), (c_5) \) and \((c_6)\). If

\[
\deg_B(g_i, \mathcal{O}_{i+1}, 0) \neq 0, \quad \text{for all } i = 1, \ldots, n - 1,
\]

and

\[
\deg_B(h^*, \mathcal{O}_1, 0) \neq 0,
\]

then there exists at least a \( T \)-periodic solution of \((C)\) in \( \Omega \).

The above corollary can be further simplified if we assume the following hypothesis which is rather natural in our framework:

\((c_3^*)\) 0 \( \in \mathcal{O}_{i+1} \) and \( g_i|_{\mathcal{O}_{i+1}} : \mathcal{O}_{i+1} \to g_i(\mathcal{O}_{i+1}) \subseteq \mathbb{R}^m \) is a homeomorphism with \( g_i(0) = 0 \), for all \( i = 1, \ldots, n - 1 \).

Notice that \((c_3^*)\) implies \((c_3), (c_4), (c_5)\) and, moreover, for every \( i = 1, \ldots, n - 1 \), \( \deg_B(g_i, \mathcal{O}_{i+1}, 0) = \pm 1 \) (the sign depending on the fact that \( g_i \) is an orientation-preserving or orientation-reversing homeomorphism). As a consequence, the following result holds.

Corollary 3.2. Let \( \Omega \subseteq \text{dom} \, M \) be an open (possibly unbounded) set. Assume \((c_1), (c_6) \) and \((c_3^*)\). If

\[
\deg_B(h^*, \mathcal{O}_1, 0) \neq 0,
\]

then there exists at least a \( T \)-periodic solution of \((C)\) in \( \Omega \).

From now on we deal with an open and bounded set \( \Omega \) with \( \overline{\Omega} \subseteq \text{dom} \, M \). In order to present the previous results in this special case, we need to slightly modify some of the hypotheses previously introduced. We will only state the results, omitting the proofs which require only obvious changes in the previous arguments.

The following theorem is a continuation result which is a variant of Theorem 3.1.

Theorem 3.2. Let \( \Omega \) be an open and bounded set with \( \overline{\Omega} \subseteq \text{dom} \, M \). Suppose that the following conditions hold.

\((c_1')\) For each \( \vartheta \in [0, 1[ \) there is no \( T \)-periodic solution of \((C_\vartheta)\) with \( x \in \partial \Omega \).

\((c_2')\) \( \hat{g}^{-1}(0) \cap \partial \Omega = \emptyset \).

If

\[
\deg_B(\hat{g}, \Omega \cap \mathbb{R}^{mn}, 0) \neq 0,
\]

then there exists at least a \( T \)-periodic solution of \((C)\) in \( \overline{\Omega} \).

We underline that Proposition 3.1 is still valid in this special framework by replacing hypothesis \((c_5)\) and \((c_6)\) with the following ones, respectively.

\((c_5')\) \( g_i(\omega) \neq 0 \) for every \( \omega \in \overline{\mathcal{O}_{i+1}} \setminus \{0\} \), for each \( i = 1, \ldots, n - 1 \).

\((c_6')\) \( (h^*)^{-1}(0) \cap \partial \mathcal{O}_1 = \emptyset \).
In particular, we recall that condition \((c'_6)\) guarantees that \(\deg_B(h^*, O_1, 0)\) is well-defined.

Then, from Theorem 3.2 together with the modification of Proposition 3.1 described above, we have the next result (analogous to Corollary 3.1).

**Corollary 3.3.** Let \(\Omega\) be an open and bounded set with \(\Omega \subseteq \text{dom } M\). Assume \((c'_1), (c_3), (c_4), (c'_5)\) and \((c'_6)\). If

\[
\deg_B(g_i, O_{i+1}, 0) \neq 0, \quad \text{for all } i = 1, \ldots, n - 1,
\]

and

\[
\deg_B(h^*, O_1, 0) \neq 0,
\]

then there exists at least a \(T\)-periodic solution of \((C)\) in \(\Omega\).

In the same spirit of Corollary 3.2, introducing the hypothesis \((c'_*)\) \(0 \in O_{i+1}\) and \(g_i|_{\overline{O}_{i+1}} : \overline{O}_{i+1} \to \mathbb{R}^m\) is a homeomorphism with \(g_i(0) = 0\), for all \(i = 1, \ldots, n - 1\), we can state the following.

**Corollary 3.4.** Let \(\Omega\) be an open and bounded set with \(\Omega \subseteq \text{dom } M\). Assume \((c'_1), (c'_6)\) and \((c'_*)\). If

\[
\deg_B(h^*, O_1, 0) \neq 0,
\]

then there exists at least a \(T\)-periodic solution of \((C)\) in \(\Omega\).

We conclude this section by showing a possible application where the hypothesis \((c'_*)\) is automatically satisfied. To this end, we consider the periodic problem associated with the \(n\)-th order differential system for \(u(t) \in \mathbb{R}^m\)

\[
(\varphi_{n-1}(\ldots (\varphi_2((\varphi_1(u'))')') \ldots'))' + k(t, u', u^{(n)}) = 0, \quad (3.2)
\]

where, for each \(i = 1, \ldots, n - 1\), \(\varphi_i : \mathbb{R}^m \to \mathbb{R}^m\) is a homeomorphism with \(\varphi_i(0) = 0\). Our study generalizes previous investigations in [6] in the scalar case \((m = 1)\). Equation (3.2) can be equivalently written as a cyclic feedback type system in \(\mathbb{R}^{mn}\) of the form

\[
\begin{align*}
x'_1 &= \varphi_1^{-1}(x_2) \\
x'_2 &= \varphi_2^{-1}(x_3) \\
& \quad \vdots \\
x'_{n-1} &= \varphi_{n-1}^{-1}(x_n) \\
x'_n &= h(t, x_1, \ldots, x_n),
\end{align*}
\]

where

\[
h(t, s_1, s_2, \ldots, s_n) := -k(t, s_1, \varphi_1^{-1}(s_2), \ldots, \varphi_{n-1}^{-1}(s_n)).
\]

Observe that \(h(t, s_1, 0, \ldots, 0) = -k(t, s_1, 0, \ldots, 0)\) and hence

\[
h^*(\omega) = -\frac{1}{T} \int_0^T k(t, \omega, 0, \ldots, 0) \, dt.
\]

From Corollary 3.4 we directly obtain the following result (the definition of the open sets \(O_i\) is the same as above). The obvious proof is omitted.
Theorem 3.3. Let $\Omega \subseteq C([0,T], \mathbb{R}^m)$ be an open and bounded set such that $0 \in \Omega_i$ for all $i = 2, \ldots, n$. Suppose that

- for each $\vartheta \in [0,1]$ there is no $T$-periodic solutions of

\[
\begin{cases}
x'_1 = \varphi^{-1}_1(x_2) \\
x'_2 = \varphi^{-1}_2(x_3) \\
\vdots \\
x'_{n-1} = \varphi^{-1}_{n-1}(x_n) \\
x'_n = \partial h(t,x_1,\ldots,x_n)
\end{cases}
\]

with $x \in \partial \Omega$;

- $h^*(\omega) \neq 0$, for every $\omega \in \partial \mathcal{O}_1$ and $\text{deg}_B(h^*, \mathcal{O}_1, 0) \neq 0$.

Then there exists at least a $T$-periodic solution $x(t)$ of (3.3) in $\Omega$.

An important case of system (3.2) is given by the second order $\phi$-Laplacian equation

\[
(\phi(u'))' + k(t,u,u') = 0,
\]  

(3.4)

where $\phi: \mathbb{R}^m \to \mathbb{R}^m$ is a homeomorphism with $\phi(0) = 0$ and $k: [0,T] \times \mathbb{R}^m \times \mathbb{R}^m \to \mathbb{R}^m$ is an $L^1$-Carathéodory function. System (3.4) plays an important role in several mathematical models and therefore our next goal is to get some applications to this class of systems. With this respect, it will be convenient to introduce the following notation. We denote by $C^1_T$ the space of continuously differentiable functions $u: [0,T] \to \mathbb{R}^m$ satisfying the boundary condition

\[
u(0) = u(T), \quad u'(0) = u'(T).
\]  

(3.5)

In this space, we take as a norm

\[
\|u\|_{C^1} := \max\{\|u\|_\infty, \|u'\|_\infty\},
\]

which is equivalent to the more standard norm $\|u\|_\infty + \|u'\|_\infty$.

We also set

\[
k^*(\omega) := \frac{1}{T} \int_0^T k(t,\omega,0) \, dt, \quad \omega \in \mathbb{R}^m.
\]

As mentioned in the introduction, a relevant continuation theorem for system (3.4), involving the homotopic equation

\[
(\phi(u'))' + \lambda k(t,u,u') = 0,
\]  

(3.6)

was achieved by Manásevich and Mawhin in [16] under some additional hypotheses on the homeomorphism $\phi$. In this setting, one could observe that equation (3.4) is equivalent to the first order cyclic system in $\mathbb{R}^{2m}$

\[
\begin{cases}
x'_1 = \phi^{-1}(x_2) \\
x'_2 = h(t,x_1,x_2)
\end{cases}
\]

(3.7)

where $h(t,x_1,x_2) := -k(t,x_1,\phi^{-1}(x_2))$ and, analogously, (3.6) can be written as

\[
\begin{cases}
x'_1 = \phi^{-1}(x_2) \\
x'_2 = \lambda h(t,x_1,x_2)
\end{cases}
\]

(3.8)
so that the continuation theorem [16, Theorem 3.1] could be derived as a corollary of Theorem 3.3 without any further condition on $\phi$. However, a deeper inspection shows that the situation is not so simple. Indeed, in [16] the condition on the homotopic equation (3.6) requires no solutions on the boundary of an open and bounded set in the $C^1_T$-norm. Due to the fact that this norm is strictly finer than the sup-norm that we consider for our approach, it seems not obvious how to include the results in [16] in our setting (except for very special cases of $\Omega$). We propose below a possible way to overcome this difficulty and thus recover Manásevich-Mawhin continuation theorem [16, Theorem 3.1], without additional hypotheses on $\phi$.

**Theorem 3.4.** Let $\mathcal{U}$ be an open and bounded set in $C^1_T$ such that the following conditions hold.

- For each $\lambda \in [0,1]$ the problem
  \[
  (\phi(u'))' + \lambda k(t,u,u') = 0, \quad u(0) = u(T), \quad u'(0) = u'(T),
  \]
  has no solution on $\partial \mathcal{U}$.
- The equation $k^* (\omega) = 0$ has no solution on $\partial \mathcal{U} \cap \mathbb{R}^m$ and
  \[
  \deg_B(k^*, \mathcal{U} \cap \mathbb{R}^m, 0) \neq 0.
  \]

Then, problem (3.4)-(3.5) has at least a solution in $\mathcal{U}$.

**Proof.** If there exists a solution in $\partial \mathcal{U}$, we are done. Then, for the rest of the proof, we assume that problem (3.4)-(3.5) has no solution in $\partial \mathcal{U}$. We split our argument into three steps.

**Step 1. Compactness.** We claim that the set
\[
\mathcal{K} := \bigcup_{\lambda \in [0,1]} \left\{ u \in \overline{\mathcal{U}} : (\phi(u'))' + \lambda k(t,u,u') = 0 \right\}
\]
is a compact subset of $\mathcal{U}$. To this end, let $(\lambda_n, u_n) \in [0,1] \times \overline{\mathcal{U}}$ be such that
\[
(\phi(u_n'))' + \lambda_n k(t,u_n,u_n') = 0.
\]

By assumption, $\overline{\mathcal{U}}$ is bounded, therefore there is a constant $r > 0$ such that $\|u\|_\infty \leq r$ and $\|u'\|_\infty \leq r$, for each $u \in \overline{\mathcal{U}}$. Then, from the Carathéodory conditions we deduce that there exists a measurable function $\rho \in L^1([0,T])$ such that $\|k(t,u_n(t),u_n'(t))\|_{\mathbb{R}^m} \leq \rho(t)$, for a.e. $t \in [0,T]$. We also introduce the uniformly continuous function $R(t) := \int_0^t \rho(\xi) \, d\xi$, for $t \in [0,T]$. The sequence $(u_n')_n$ is equicontinuous. Indeed,
\[
u_n(t) = \phi^{-1}(v_n(t)), \quad \text{where} \quad v_n(t) := \phi(u_n'(0)) - \lambda_n \int_0^t k(\xi, u_n(\xi), u_n'(\xi)) \, d\xi,
\]
and $v_n$ is uniformly bounded on $[0,T]$ by the constant
\[
r_1 := \max \left\{ \|\phi(z)\|_{\mathbb{R}^m} : \|z\|_{\mathbb{R}^m} \leq r \right\} + R(T).
\]
Actually, with separately the case in which \( \bar{\lambda} \) above and the dominated convergence theorem, we find that \( \lambda_0 \) is a periodic solution of \( \lambda_0 U := \{ u \in C^1 : u \in U_1, u' \in U_2 \} \).

We write (3.4) as an equivalent first order cyclic system in \( u \) solutions on the boundary. Defining \( x \in \partial \Omega \), we immediately conclude that \( \bar{\lambda} \in [0, 1] \). By the assumption of no solutions on the boundary, we must have \( \bar{\lambda} \in U \). We study now separately the case in which \( \bar{\lambda} = 0 \). In this case, by the same computations as above and the dominated convergence theorem, we find that \( \phi(u(t)) = \phi(u'(0)) \) for all \( t \in [0, T] \), so that (recalling that \( \bar{u} \in \bar{U} \) satisfies (3.4)), \( \bar{u} \) is constant, that is \( \bar{u}(t) = \bar{\omega} \) for some \( \bar{\omega} \in \bar{U} \cap \bar{R}^m \). Finally, the second hypothesis in the theorem ensures that \( \bar{\omega} \in \bar{U} \). The claim is proved.

**Step 2. A special case for the domain.** Suppose that there exist two open bounded sets \( U_1, U_2 \in C([0, T], \bar{R}^m) \) with \( 0 \in U_2 \) such that

\[
\mathcal{U} := \{ u \in C^1 : u \in U_1, u' \in U_2 \}.
\]

We write (3.4) as an equivalent first order cyclic system in \( \bar{R}^{2m} \) of the form (3.7) with \( h(t, x_1, x_2) := -k(t, x_1, \bar{\lambda}^{-1}(x_2)) \).

In the Banach space \( X := C([0, T], \bar{R}^{2m}) \) we define the set

\[
\Omega := U_1 \times \phi(U_2) = \{ x = (x_1, x_2) \in X : x_1 \in U_1, \bar{\lambda}^{-1}(x_2) \in U_2 \}.
\]

Clearly the set \( \Omega \) is open and bounded in \( X \).

With these positions, we can easily check that the first hypothesis of the theorem implies that system (3.8) has no \( T \)-periodic solution \( x \in \partial \Omega \), for any \( \lambda \in [0, 1] \), actually for any \( \lambda \in [0, 1] \), because we have started the proof by assuming that (3.4) has no solution on the boundary. We are therefore in the setting of Theorem 3.3 with its first condition satisfied. Also the second condition in Theorem 3.3 holds, because it follows directly from the second hypothesis of the present theorem. Then, we can apply Theorem 3.3 and we obtain that there exists at least a \( T \)-periodic solution \( x(t) = (x_1(t), x_2(t)) \) of (3.3) in \( \overline{U} \). Actually, we have \( x \in \Omega \) (since we have started our proof by assuming that there are no solutions on the boundary). Defining \( u(t) := x_1(t) \) for \( t \in [0, T] \), we immediately conclude that \( u = x_1 \in U_1, u' = \bar{\lambda}^{-1}(x_2) \in U_2 \), then \( u \in \mathcal{U} \), and \( u(t) \) satisfies (3.4) and (3.5).
Step 3. General case. Let $U \in C_T^1$ be an open and bounded set. From Step 1, $K$ is a compact subset of $U$. Therefore, for each point $w \in K$ there is an open ball $B(w, r_w) \subseteq U$, in the $C_T^1$-norm, which is a set of the product form as the one in Step 2. Indeed, $u \in B(w, r_w)$ if and only if $\|u - w\|_\infty < r_w$ and $\|u' - w'\|_\infty < r_w$. By a standard compactness argument, we have

$$K \subseteq \bigcup_{\alpha = 1}^\ell U^\alpha,$$

with $U^\alpha \subseteq U$ an open (and bounded) set of the form

$$U^\alpha := \{ u \in C_T^1 : u \in U^\alpha_1, u' \in U^\alpha_2 \},$$

(3.9)

where $U^\alpha_1, U^\alpha_2 \in C([0, T], \mathbb{R}^m)$ are open (bounded) set.

We notice that, since $\deg_B(k^*, U \cap \mathbb{R}^m, 0) \neq 0$, there exists at least a constant solution in $K$ and therefore at least one of the sets $U^\alpha$ contains an element of the form $\omega \in U \cap \mathbb{R}^m$. This in turn means that at least one of the $U^\alpha_2$ contains the element 0.

Next, we define the set

$$\Omega := \bigcup_{\alpha = 1}^\ell \Omega^\alpha, \quad \text{where } \Omega^\alpha := U^\alpha_1 \times \phi(U^\alpha_2).$$

Clearly the set $\Omega$ is open and bounded in $X$. Moreover, if $u \in \partial \Omega$ then there exists at least an index $\alpha \in \{1, \ldots, \ell\}$ such that $u \in \partial \Omega^\alpha$. From the above remark, we also have that $0 \in \phi(U^\alpha_2)$ for at least an index $\alpha \in \{1, \ldots, \ell\}$.

Finally, arguing as in Step 2, it is easy to check the validity of all the hypotheses of Theorem 3.3 and thus we obtain that there exists at least a $T$-periodic solution $x(t) = (x_1(t), x_2(t))$ of (3.3) in $\Omega$ (actually, $x \in \Omega$). Defining $u(t) := x_1(t)$ for $t \in [0, T]$, we immediately conclude that there is an index $\alpha \in \{1, \ldots, \ell\}$ such that $u = x_1 \in U^\alpha_1$, $u' = \phi^{-1}(x_2) \in U^\alpha_2$. Then $u \in U$, and $u(t)$ satisfies (3.4) and (3.5).

The theorem is thus proved. \qed

Remark 3.2. In [16, 17, 18], Manásevich and Mawhin consider a class of continuous functions $\phi : \mathbb{R}^m \to \mathbb{R}^m$ satisfying

(H1) for every $x_1, x_2 \in \mathbb{R}^m, x_1 \neq x_2$, $\langle \phi(x_1) - \phi(x_2), x_1 - x_2 \rangle > 0$;

(H2) there exists a function $\alpha : [0, +\infty) \to [0, +\infty)$, with $\alpha(s) \to +\infty$ as $s \to +\infty$, such that $\langle \phi(x), x \rangle \geq \alpha(|x|)|x|$ for all $x \in \mathbb{R}^m$.

From these two conditions it follows that the map $\phi : \mathbb{R}^m \to \mathbb{R}^m$ is a homeomorphism such that $\phi(0) = 0$. Clearly our hypotheses cover the case considered in [16, 17, 18] and, moreover, it is more general as explained below and in Figure 1.

Under our conditions we can deal with a continuous function built in the following manner. For $i = 1, \ldots, n$, let $h_i : \mathbb{R} \to \mathbb{R}$ be a homeomorphism such that $h_i(0) = 0$. Let $M \in GL_n(\mathbb{R})$ be an invertible matrix in $\mathbb{R}^{m \times m}$. The function $\phi : \mathbb{R}^m \to \mathbb{R}^m$ defined as

$$\begin{pmatrix} u_1 \\ \vdots \\ u_n \end{pmatrix} \mapsto M \begin{pmatrix} h_1(u_1) \\ \vdots \\ h_n(u_n) \end{pmatrix}$$

26
is a homeomorphism. Figure 1 shows another type of homeomorphism $\phi: \mathbb{R}^2 \rightarrow \mathbb{R}^2$ which does not satisfy conditions $(H1)$ and $(H2)$.

Figure 1: The figure shows an example of a homeomorphism $\phi: \mathbb{R}^2 \rightarrow \mathbb{R}^2$ which does not satisfy conditions $(H1)$ and $(H2)$. We consider a function $\phi = (\phi_1, \phi_2)$ defined as

$$\phi_1(x, y) := \frac{(3x + y^3)/40}{3}, \quad \phi_2(x, y) := \frac{(\sin(2(x - y)^3) + 2(x - y)^4)/10}{3}.$$

We illustrate how the square $[-1, 1] \times [-1, 1] \subseteq \mathbb{R}^2$ (on the left) is mapped by the function $\phi$ (figure on the right). For example the points $(-1, 2), (5, 6)$ do not satisfy $(H1)$ and the point $(-2, -2)$ does not satisfy $(H2)$.

4 Periodic solutions to cyclic feedback systems: homotopy to an autonomous system

In this section we continue the study of the differential system $(\mathcal{C})$ introduced in Section 3. We keep all the basic assumptions for $(\mathcal{C})$ considered therein, as well as the abstract framework for the coincidence degree. As an application, we give a continuation theorem which involves an homotopy between $(\mathcal{C})$ and the autonomous differential system

$$(\mathcal{C}_0)$$

$$\begin{cases}
x_1' = g_1(x_2) \\
x_2' = g_2(x_3) \\
\vdots \\
x_{n-1}' = g_{n-1}(x_n) \\
x_n' = h_0(x_1, \ldots, x_n),
\end{cases}$$

where $h_0: \mathbb{R}^m \times \cdots \times \mathbb{R}^m \rightarrow \mathbb{R}^m$ is a continuous function. In detail, we consider an auxiliary function $\tilde{h}: [0, T] \times \mathbb{R}^m \times \cdots \times \mathbb{R}^m \times [0, 1] \rightarrow \mathbb{R}^m$, satisfying the $L^1$-Carathéodory conditions and such that

$$\begin{align*}
\tilde{h}(t, x_1, \ldots, x_n, 1) &= h(t, x_1, \ldots, x_n), \\
\tilde{h}(t, x_1, \ldots, x_n, 0) &= h_0(x_1, \ldots, x_n).
\end{align*}$$

(4.1)

Consistently with the previous notation, since $M$ is the Nemytskii operator associated with $h$, we denote by $\tilde{M}$ the corresponding operator associated with
We also introduce the autonomous vector field
\[ \hat{g}_0(s) := (g_1(s_2), \ldots, g_{n-1}(s_n), h_0(s)), \quad s = (s_1, \ldots, s_n) \in \mathbb{R}^{mn}. \]

In the next results, when we write \( \Omega \subseteq \text{dom} \hat{M} \) (or \( \tilde{\Omega} \subseteq \text{dom} \tilde{M} \), we in fact consider only the case of \( \Omega \subseteq X = C([0,T], \mathbb{R}^{mn}) \). However, in principle, the same results could be applied (using Theorem A.3) also to a more general situation, as explained in Remark 3.1 (see also Section 6).

We are now in position to state our first result, which is a direct consequence of [5, Theorem 1] and of the homotopic invariance of the coincidence degree (cf. Lemma 2.1).

Lemma 4.1. Let \( \Omega \) be an open and bounded set with \( \hat{\Omega} \subseteq \text{dom} \hat{M} \). Suppose that the following condition holds.
\[ (a'_1) \quad \text{For each} \ \lambda \in [0,1] \ \text{there is no} \ T\text{-periodic solution of} \]
\[ (C_0^\lambda) \]
\[ \begin{align*}
  x'_1 &= g_1(x_2) \\
  x'_2 &= g_2(x_3) \\
  &\vdots \\
  x'_{n-1} &= g_{n-1}(x_n) \\
  x'_n &= \tilde{h}(t, x_1, \ldots, x_n, \lambda)
\end{align*} \]
\[ \text{with} \ x \in \partial \Omega. \]

Then
\[ D_L(L - M, \Omega) = (-1)^{mn} \deg_B(\hat{g}_0, \Omega \cap \mathbb{R}^{mn}, 0). \]

From this result the next one follows immediately (see [5, Theorem 2] and Theorem 1.2 in the introduction).

Theorem 4.1. Let \( \Omega \) be an open and bounded set with \( \tilde{\Omega} \subseteq \text{dom} \tilde{M} \). Suppose that the following conditions hold.
\[ \begin{itemize}
  \item For each \ \lambda \in [0,1] \ there is no \ T\text{-periodic solution of} \]
\[ (C_\lambda^0) \]
\[ \begin{align*}
  x'_1 &= g_1(x_2) \\
  x'_2 &= g_2(x_3) \\
  &\vdots \\
  x'_{n-1} &= g_{n-1}(x_n) \\
  x'_n &= \tilde{h}(t, x_1, \ldots, x_n, \lambda)
\end{align*} \]
\[ \text{with} \ x \in \partial \Omega. \]
\[ \text{and} \ \deg_B(\hat{g}_0, \Omega \cap \mathbb{R}^{mn}, 0) \neq 0. \]
\[ \text{Then there exists at least a} \ T\text{-periodic solution of} \ (C) \ \text{in} \ \tilde{\Omega}. \]

In this manner, we reduce part of our problem to the study of the degree of \( \hat{g}_0 \) and for this purpose we can take advantage of the conditions considered in the previous section. We can thus produce results analogous to Corollary 3.3 and Corollary 3.4. With this respect, it is convenient to introduce the function
\[ h_0^\ast: \mathbb{R}^m \rightarrow \mathbb{R}^m \]
\[ \text{defined as} \]
\[ h_0^\ast(\omega) := h_0(\omega, 0, \ldots, 0), \quad \omega \in \mathbb{R}^m. \]

The analogous of Corollary 3.4 is the following, where the open sets \( \mathcal{O}_i \) are defined as in the previous section.

Corollary 4.1. Let \( \Omega \) be an open and bounded set with \( \tilde{\Omega} \subseteq \text{dom} \tilde{M} \). Assume \( (a'_1) \) and also the following conditions
\[ \text{and} \]
\[ \text{Theorem 4.1.} \]
\[ \text{Lemma 4.1.} \]
\[ \text{Corollary 4.1.} \]
\[(a_0') \ (h_0')^{-1}(0) \cap \partial \mathcal{O}_1 = \emptyset; \]
\[(a_0') \ 0 \in \mathcal{O}_{i+1} \text{ and } g_i|_{\mathcal{O}_{i+1}}: \mathcal{O}_{i+1} \to g_i(\mathcal{O}_{i+1}) \subseteq \mathbb{R}^m \text{ is a homeomorphism with } g_i(0) = 0, \text{ for all } i = 1, \ldots, n - 1. \]

If \[\text{deg}_B(h_0', \mathcal{O}_1, 0) \neq 0,\]
then there exists at least a \(T\)-periodic solution of \((C)\) in \(\Omega\).

All the results presented in this section can be stated also in the case of an open possibly unbounded set \(\Omega \subseteq \text{dom } \tilde{M}\). For this aim, one have to follow the scheme presented in Section 3 and a modification of [1, Theorem 1] for open (not necessarily bounded) sets, which is discussed in Appendix A.

In particular, the analogous of Theorem 4.1 is the following result (corresponding to Theorem 3.1).

**Theorem 4.2.** Let \(\Omega \subseteq \text{dom } M\) be an open (possibly unbounded) set. Suppose that the following conditions hold.

- There exists a compact set \(K \subseteq \Omega\) containing all the possible \(T\)-periodic solutions of \((C)\) for any \(\lambda \in [0, 1]\).
- \[\text{deg}_B(\tilde{h}_0, \Omega \cap \mathbb{R}^m, 0) \neq 0.\]

Then there exists at least a \(T\)-periodic solution of \((C)\) in \(\Omega\).

Now, at this point, we can repeat (almost step by step) the results obtained in Section 3 for system (3.2). The only difference is that the continuation theorem will make use of an homotopy leading system (3.3) to an autonomous system of the form

\[
\begin{align*}
x_1' &= \varphi_1^{-1}(x_2) \\
x_2' &= \varphi_2^{-1}(x_3) \\
& \quad \vdots \\
x_{n-1}' &= \varphi_{n-1}^{-1}(x_n) \\
x_n' &= h_0(x_1, \ldots, x_n). 
\end{align*}
\]

In this setting, the analogous of Theorem 3.3 is the next result, where the function \(\tilde{h}\) is defined as in (4.1).

**Theorem 4.3.** Let \(\Omega \subseteq C([0, T], \mathbb{R}^m)\) be an open and bounded set such that \(0 \in \mathcal{O}_i\) for all \(i = 2, \ldots, n\). Suppose that

- for each \(\lambda \in [0, 1]\) there is no \(T\)-periodic solutions of

\[
\begin{align*}
x_1' &= \varphi_1^{-1}(x_2) \\
x_2' &= \varphi_2^{-1}(x_3) \\
& \quad \vdots \\
x_{n-1}' &= \varphi_{n-1}^{-1}(x_n) \\
x_n' &= h(t, x_1, \ldots, x_n, \lambda) 
\end{align*}
\]

with \(x \in \partial \Omega\);
• $h_0^*(\omega) \neq 0$, for every $\omega \in \partial \Omega_1$ and $\deg_B(h_0^*, \Omega_1, 0) \neq 0$.

Then there exists at least a $T$-periodic solution $x(t)$ of (3.3) in $\overline{\Omega}$.

The proof is omitted as it is a direct consequence of Corollary 4.1.

As in the final part of Section 3, we propose an application to the second order $\phi$-Laplacian equation (3.4). In the present case, instead of equation (3.6), we consider the system

$$
(\phi(u'))' + \tilde{k}(t, u, u', \lambda) = 0,
$$

where $\tilde{k} : [0, T] \times \mathbb{R}^m \times \mathbb{R}^m \times [0, 1] \rightarrow \mathbb{R}^m$ is an $L^1$-Carathéodory function such that

$$
\tilde{k}(t, x_1, x_2, 0) = k_0(x_1, x_2),
$$

with $k_0 : \mathbb{R}^m \times \mathbb{R}^m \rightarrow \mathbb{R}^m$ an autonomous field.

Now we are in a position to prove the following continuation theorem which corresponds to [16, Theorem 4.1] (but without any additional assumption on the homeomorphism $\phi$).

**Theorem 4.4.** Let $U$ be an open and bounded set in $C^1_T$ such that the following conditions hold.

• For each $\lambda \in [0, 1]$ the problem

$$
(\phi(u'))' + \tilde{k}(t, u, u', \lambda) = 0, \quad u(0) = u(T), \quad u'(0) = u'(T),
$$

has no solution on $\partial U$.

• The Brouwer degree

$$
\deg_B(k_0(\cdot, 0), U \cap \mathbb{R}^m, 0) \neq 0.
$$

Then, problem (3.4)-(3.5) has at least a solution in $U$.

**Proof.** If there exists a solution in $\partial U$, we are done. Then, for the rest of the proof, we assume that problem (3.4)-(3.5) has no solution in $\partial U$. We split our argument into three steps, which are the same as in the proof of Theorem 3.4.

**Step 1. Compactness.** The set

$$
K := \bigcup_{\lambda \in [0, 1]} \left\{ u \in \overline{U} : (\phi(u'))' + \tilde{k}(t, u, u', \lambda) = 0 \right\}
$$

is a compact subset of $\mathcal{U}$. To check this claim we just repeat (with obvious changes) the proof of Step 1 of Theorem 3.4.

**Step 2. A special case for the domain.** Suppose that there exist two open bounded sets $U_1, U_2 \in C([0, T], \mathbb{R}^m)$ with $0 \in U_2$ such that

$$
U = \{ u \in C^1_T : u \in U_1, u' \in U_2 \}.
$$

We write (4.2) as an equivalent first order cyclic system in $\mathbb{R}^{2m}$ of the form

$$
\begin{cases}
    x'_1 = \phi^{-1}(x_2) \\
    x'_2 = \tilde{h}(t, x_1, x_2, \lambda),
\end{cases}
$$
where \( \tilde{h}(t, x_1, x_2, \lambda) := -\tilde{k}(t, x_1, \phi^{-1}(x_2), \lambda) \).

In the Banach space \( X := C([0, T], \mathbb{R}^{2m}) \) we define the open and bounded set

\[
\Omega := \mathcal{U}_1 \times \phi(\mathcal{U}_2) = \{ x = (x_1, x_2) \in X : x_1 \in \mathcal{U}_1, \phi^{-1}(x_2) \in \mathcal{U}_2 \}.
\]

We can now apply Theorem 4.3 (analogously as we applied Theorem 3.3 in Step 2 in the proof of Theorem 3.4) and obtain the existence of at least a \( T \)-periodic solution \((x_1(t), x_2(t)) \in \Omega \) of

\[
\begin{align*}
x_1' &= \phi^{-1}(x_2) \\
x_2' &= h(t, x_1, x_2),
\end{align*}
\]

for \( h(t, x_1, x_2) := -k(t, x_1, \phi^{-1}(x_2)) \). Then, the first component \( u := x_1 \) of such a solution is a solution of (3.4) with \( u \in \mathcal{U} \).

**Step 3. General case.** Let \( \mathcal{U} \in C^1_T \) be an open and bounded set. Recalling Step 1, we know that \( K \) is a compact subset of \( \mathcal{U} \) and we cover it by a finite number of open sets \( \mathcal{U}^\alpha \) as in (3.9). From this point on, the proof follows the same lines as those of Step 3 in the proof of Theorem 3.4 and we can conclude.

### 5 Periodic solutions to Hartman-type perturbations of the \( \phi \)-Laplacian operator

As an application of the previous continuation results, we propose a further variant of the Hartman-Knobloch theorem for the \( T \)-periodic problem associated with the vector second order differential equation

\[
(\phi(u'))' + f(t, u) = 0,
\]

where \( f: [0, T] \times \mathbb{R}^m \rightarrow \mathbb{R}^m \) is a continuous function and \( \phi: \mathbb{R}^m \rightarrow \mathbb{R}^m \) is a homeomorphism with \( \phi(0) = 0 \).

A classical result of Hartman [11] guarantees the existence of a solution for the two-point (Dirichlet) boundary value problem associated with

\[
u'' + f(t, u) = 0,
\]

by assuming the existence of a constant \( R > 0 \) such that

\[
\langle f(t, \xi), \xi \rangle \leq 0, \quad \forall t \in [0, T], \forall \xi \in \mathbb{R}^m \text{ with } \|\xi\|_{\mathbb{R}^m} = R.
\]

Under the same conditions, Knobloch in [12] obtained an existence result for the periodic problem and with a Lipschitzian \( f \) (see also [22], dealing with a continuous \( f \)). Both Hartman and Knobloch results apply also to more general systems of the form

\[
u'' + f(t, u, u') = 0,
\]

under suitable growth conditions on \( u' \) of Bernstein-Nagumo type. For simplicity, we do not pursue our study in this direction and refer to [7, 22] for interesting surveys and information on this topic.
In [24], Mawhin extended the theorems for equation (5.2) to systems of the form (5.1) for a \( p \)-Laplacian differential operator, namely for \( \phi(\xi) = \psi_p(\xi) \), where

\[
\psi_p(\xi) := |\xi|^{p-2} \xi, \quad \xi \in \mathbb{R}^m \setminus \{0\}, \quad \psi_p(0) = 0,
\]

for \( p > 1 \) (see also [25]). The corresponding results for system (5.4) were generalized to the \( p \)-Laplacian operator by Mawhin and Ureña in [28].

We plan now to present a version of Knobloch theorem, limited to the case of (5.2), for system (5.1) and involving a class of nonlinear differential operators which are not included in those studied in [16, 25]. In any case, we shall borrow some arguments already developed in [24] and [28] in the case of \( \phi = \psi_p \). Thus our computations are in debt of those performed in the above quoted papers; indeed we show that they can be reproduced in our more general setting, by virtue of the continuation theorems developed in the previous sections.

In the following lemma we obtain an a priori bound for the derivative of the solution to a parameter-dependent equation of the form

\[
\left( \phi(u') \right)' + \tilde{f}(t, u, \lambda) = 0,
\]

where \( \tilde{f} : [0, T] \times \mathbb{R}^m \times [0, 1] \to \mathbb{R}^m \) is a continuous function.

Using the continuity of \( \tilde{f} \), for any constant \( d > 0 \) we define

\[
C_d := \max \{ \|f(t, \xi, \lambda)\|_{\mathbb{R}^m} : t \in [0, T], \xi \in B[0, d], \lambda \in [0, 1] \}.
\]

**Lemma 5.1.** Let us suppose that

\[
\lim_{|\xi| \to +\infty} \langle \phi(\xi), \xi \rangle = +\infty.
\]

Then, for every \( d > 0 \) there exists \( M_d > 0 \) such that \( \|u'\|_\infty < M_d \), whenever \( u(t) \) is a \( T \)-periodic solution \( u(t) \) of (5.6), for some \( \lambda \in [0, 1] \), with \( \|u\|_\infty \leq d \).

**Proof.** Let \( u(t) \) be a \( T \)-periodic solution of (5.6) with \( \|u\|_\infty \leq d \). We divide the proof into two steps.

**Step 1.** We claim that there exist a point \( t_0 \in [0, T] \) and a constant \( L_d > 0 \) such that \( \|u'(t_0)\|_{\mathbb{R}^m} \leq L_d \).

By multiplying equation (5.6) by \( u(t) \) and by integrating in \([0, T] \), we obtain

\[
- \int_0^T \langle (\phi(u'(t)))', u(t) \rangle dt = \int_0^T \langle \tilde{f}(t, u(t), \lambda), u(t) \rangle dt
\]

and thus

\[
\frac{1}{T} \int_0^T \langle \phi(u'(t)), u'(t) \rangle dt = \frac{1}{T} \int_0^T \langle \tilde{f}(t, u(t), \lambda), u(t) \rangle dt \leq dC_d.
\]

By the mean value theorem, there exists \( t_0 \in [0, T] \) such that

\[
\langle \phi(u'(t_0)), u'(t_0) \rangle \leq dC_d.
\]

From the hypothesis of the lemma, there exists \( L_d > 0 \) such that if \( \|\xi\|_{\mathbb{R}^m} > L_d \) then \( \langle \phi(\xi), \xi \rangle > dC_d \). Therefore we conclude that \( \|u'(t_0)\|_{\mathbb{R}^m} \leq L_d \).
Step 2. By integrating \(5.6\) in \([t_0, t]\), for \(t \in [0, T]\), we deduce
\[
\phi(u'(t)) = \phi(u'(t_0)) - \int_{t_0}^{t} f(s, u(s), \lambda) \, ds
\]
and thus
\[
\|\phi(u'(t))\|_{\mathbb{R}^m} \leq \|\phi(u'(t_0))\|_{\mathbb{R}^m} + TC_d.
\]
Next, by defining
\[
K_d := \sup \{ \|\phi(\xi)\|_{\mathbb{R}^m} : \xi \in \mathbb{R}^m, \|\xi\|_{\mathbb{R}^m} \leq L_d \},
\]
we have
\[
\|\phi(u'(t))\|_{\mathbb{R}^m} \leq K_d + TC_d, \quad \forall t \in [0, T],
\]
and hence
\[
u'(t) = \phi^{-1}(B[0, K_d + TC_d]), \quad \forall t \in [0, T].
\]
Now, it is sufficient to take as \(M_d > 0\) any real number such that
\[
\phi^{-1}(B[0, K_d + TC_d]) \subseteq B(0, M_d).
\]
The lemma is thus proved. \(\Box\)

The following existence result holds.

**Theorem 5.1.** Let \(A : \mathbb{R}^m \setminus \{0\} \to [0, +\infty[\) be a continuous function and let
\[
\phi(\xi) := A(\xi)\xi, \quad \text{if } \xi \in \mathbb{R}^m \setminus \{0\}, \quad \phi(0) = 0. \tag{5.7}
\]
Suppose that \(\phi : \mathbb{R}^m \to \mathbb{R}^m\) is a homeomorphism. If there exists \(R > 0\) such that Hartman’s condition \(5.3\) holds, then there exists at least a \(T\)-periodic solution \(u(t)\) of \(5.1\) such that \(\|u(t)\|_{\mathbb{R}^m} \leq R\) for all \(t \in [0, T]\).

**Proof.** We shall propose two different proofs. The first one is based on Theorem 4.4 and is partially inspired by the approach introduced by Mawhin in [24]. The second one will be only sketched and is based on Theorem 3.4 following the approach in [25].

We introduce a function \(\tilde{f}(t, \xi, \lambda)\) such that
\[
\tilde{f}(t, \xi, 1) = f(t, \xi), \quad \tilde{f}(t, \xi, 0) = -\xi, \quad t \in [0, T], \quad \xi \in \mathbb{R}^m,
\]
and
\[
\langle \tilde{f}(t, \xi, \lambda), \xi \rangle < 0, \quad \forall t \in [0, T], \forall \xi \in \mathbb{R}^m \text{ with } \|\xi\|_{\mathbb{R}^m} = R, \forall \lambda \in [0, 1]. \tag{5.8}
\]
In view of Hartman’s condition \(5.3\), a suitable choice of \(\tilde{f}\) could be
\[
\tilde{f}(t, \xi, \lambda) = \lambda f(t, \xi) - (1 - \lambda)\xi.
\]
Since \(\phi : \mathbb{R}^m \to \mathbb{R}^m\) is a homeomorphism, it follows that \(|\phi(\xi)| \to +\infty\) as \(|\xi| \to +\infty|\). Then, by the structure of \(\phi\) we have chosen, we have that \(A(\xi)|\xi| \to +\infty\) as \(|\xi| \to +\infty|\). Hence, \(\langle \phi(\xi), \xi \rangle = A(\xi)|\xi|^2 \to +\infty\) as \(|\xi| \to +\infty|\). Therefore, the hypothesis of Lemma \(5.1\) is satisfied and thus there exists a constant \(M_R > 0\) such that \(\|u''\|_{\infty} < M_R\) for any \(T\)-periodic solution \(u(t)\) of \(5.6\) (for some \(\lambda \in [0, 1]\)) such that \(\|u\|_{\infty} \leq R\).
We are going to apply Theorem 4.4 to the set
\[ \mathcal{U} := \{ u \in C^1_T : \|u\|_\infty < R, \|u'\|_\infty < M_R \}. \] (5.9)

First, we prove that the \( T \)-periodic problem associated with (5.6), for \( \lambda \in [0, 1] \), has no solution on \( \partial \mathcal{U} \). As already observed, from Lemma 5.1 we deduce that every solution \( u \in \mathcal{U} \) satisfies \( \|u'\|_\infty < M_R \). Therefore, to prove our claim we have only to verify that if \( u \in \mathcal{U} \) is a \( T \)-periodic solution of (5.6) for some \( \lambda \in [0, 1] \), then \( \|u\|_\infty < R \).

By contradiction, assume that there exists a \( T \)-periodic solution \( u(t) \) of (5.6) (for some \( \lambda \in [0, 1] \)) such that \( \|u\|_\infty = R \). Then, there exists \( t^* \in [0, T] \) such that \( \|u(t^*)\|_\infty = R \) and \( t^* \) a point of maximum for \( \|u(t)\|_\infty \). By the \( T \)-periodicity of the map \( t \rightarrow \|u(t)\|_\infty \), we have that \( t^* \) is a critical point and therefore (by differentiating) \( (u'(t^*), u(t^*)) = 0 \). Next, we observe that, if \( u'(t^*) = 0 \), then \( \phi(u'(t^*)) = 0 \), while, if \( u'(t^*) \neq 0 \), then (by the particular form of \( \phi \))
\[ \langle \phi(u'(t^*)), u(t^*) \rangle = A(u'(t^*)) \langle u'(t^*), u(t^*) \rangle = 0. \]

From the equality
\[ \frac{d}{dt} \langle \phi(u'(t^*)), u(t) \rangle = -\langle \tilde{f}(t, u(t), \lambda), u(t) \rangle + \langle \phi(u'(t^*)), u'(t^*) \rangle \]
and condition (5.8), we obtain that
\[ \frac{d}{dt} \langle \phi(u'(t^*)), u(t) \rangle|_{t=t^*} > 0. \]
We thus have proved that the function \( v(t) := \langle \phi(u'(t^*)), u(t) \rangle \) is such that \( v(t^*) = 0 \) and \( v'(t^*) > 0 \). We deduce the existence of \( \varepsilon > 0 \) such that
\begin{align*}
    v(t) < 0, & \quad \text{for all } t \in [t^* - \varepsilon, t^*], \\
    v(t) > 0, & \quad \text{for all } t \in [t^*, t^* + \varepsilon].
\end{align*}
Both the above inequalities are meaningful also if \( t^* = 0 \) or if \( t^* = T \), because, in this case, \( |u(0)| = |u(T)| = \|u\|_\infty = R \) and also \( v(0) = v(T) \). More precisely, if such a situation occurs, we read the first inequality for \( t^* = T \) and the second one for \( t^* = 0 \). The special form of \( \phi \) implies that
\begin{align*}
    \langle u'(t), u(t) \rangle < 0, & \quad \text{for all } t \in [t^* - \varepsilon, t^*], \\
    \langle u'(t), u(t) \rangle > 0, & \quad \text{for all } t \in [t^*, t^* + \varepsilon].
\end{align*}
Then, since
\[ \frac{d}{dt} \|u(t)\|_\infty^2 = 2 \langle u'(t), u(t) \rangle, \]
we obtain that \( t = t^* \) cannot be a maximum point for the function \( \| \cdot \|_\infty \), a contradiction.

The second hypothesis of Theorem 4.4 follows directly from the fact that
\[ \tilde{f}(t, \xi, 0) = -\xi \]
and, clearly, the degree \( \text{deg}_{\mathbb{S}}(-Id_{\mathbb{R}^m}, \mathcal{U} \cap \mathbb{R}^m, 0) \) is nonzero.

The theorem is thus proved as an application of Theorem 4.4.

34
The same theorem can be proved also using Theorem 3.4. We give just a sketch of the proof. As in [28] we suppose that Hartman’s condition (5.3) holds with a strict inequality, namely

\[ \langle f(t, \xi), \xi \rangle < 0, \quad \forall t \in [0, T], \forall \xi \in \mathbb{R}^m \quad \text{with } \|\xi\|_{\mathbb{R}^m} = R. \tag{5.10} \]

Then, using the same argument as above, we prove that system (5.6) for

\[ \tilde{f}(t, \xi, \lambda) := \lambda f(t, \xi) \]

satisfies the following condition: for each \( \lambda \in (0, 1] \), there are no (\( T \)-periodic) solutions on the boundary of \( \mathcal{U} \) (where \( \mathcal{U} \) is defined as in (5.9)). Moreover, consistently with the notation in Theorem 3.4, we have

\[ k^*(\omega) := \frac{1}{T} \int_{0}^{T} f(t, \omega) \, dt, \quad \omega \in \mathbb{R}^m, \]

and, by (5.10), we obtain \( \langle k^*(\omega), \omega \rangle < 0 \) for all \( \omega \in \partial B(0, R) = \partial \mathcal{U} \cap \mathbb{R}^m \). Hence,

\[ \deg_B(k^*, \mathcal{U} \cap \mathbb{R}^m, 0) = \deg_B(-Id_{\mathbb{R}^m}, \mathcal{U} \cap \mathbb{R}^m, 0) = (-1)^m \neq 0. \]

At this point Theorem 3.4 implies the existence of at least a \( T \)-periodic solution of (5.1) with \( \|u\|_{\infty} \leq R \) (and also \( \|u'\|_{\infty} \leq M_R \)). Since the result is obtained under the strict inequality (5.10) in Hartman’s condition, it remains to prove the theorem within the original inequality (5.3).

To achieve this latter step, we approximate the vector field with functions of the form

\[ f(t, \xi) - \varepsilon \xi \quad \text{(with } \varepsilon \to 0^+ \text{)} \]

and use the a priori bounds for the solutions. We skip this part since it has been already fully developed in [28].

**Remark 5.1.** Obviously any vector \( p \)-Laplacian differential operator defined through a homeomorphism \( \psi_p \), defined as in (5.5) for \( p > 1 \), satisfies the assumption of \( \phi \) in Theorem 5.1. On the other hand, it is possible to provide simple examples of homeomorphisms satisfying (5.7) which do not belong to the class of the \( \psi_p \)-functions considered in (5.5). For instance, the map

\[ \phi(\xi) := (\arctan |\xi|)\xi, \quad \xi \in \mathbb{R}^m, \tag{5.11} \]

fits well for Theorem 5.1 and is not in the \( p \)-Laplacian class.

The homeomorphism defined in (5.11) is a special case of a class of maps of the form

\[ \phi(\xi) := \gamma(|\xi|)\xi, \quad \text{if } \xi \in \mathbb{R}^m \setminus \{0\}, \quad \phi(0) = 0, \tag{5.12} \]

with \( \gamma(s) \) a positive continuous function defined for \( s > 0 \). Such class of operators is clearly included in that of the form (5.7) and it has been considered in [13] for the singular case, namely for \( \phi \) defined on an open ball \( B(0, a) \) and, consequently, for \( \gamma(s) \) with \( 0 < s < a < +\infty \).

A natural question which raises in this context is whether the homeomorphisms \( \phi \) of the form (5.7) (and thus, in particular, (5.12)) belong to the class of nonlinear operators introduced by Manásevich and Mawhin in [16] and satisfying conditions (H1) and (H2) recalled in Remark 3.2. With this respect, we observe that (H2) is always satisfied, since \( \langle \phi(x), x \rangle \equiv |\phi(x)||x| \geq \alpha(|x|)|x| \) for the map \( \alpha(s) \) defined as

\[ \alpha(s) := \min \{|\phi(x)| : |x| = s\}, \quad s \geq 0, \]
and such that \( \alpha(s) \to +\infty \) as \( s \to +\infty \).

Concerning condition (H1) we claim that the homeomorphisms defined by (5.12) satisfy this condition. Indeed, for the proof of (H1) we proceed as follows. First of all, we notice that a homeomorphism of the form (5.12) transforms any radial line \( \{ \phi \tilde{v}; \tilde{v} \geq 0 \} \) homeomorphically onto itself (where \( \tilde{v} \in S^{m-1} \) is an arbitrary unit vector). Hence (by the positivity of \( \gamma \)) we immediately deduce that the map \( \zeta: \mathbb{R}^+ \to \mathbb{R}^+ \) defined by \( \zeta(s) := \gamma(s)s \) for \( s > 0 \) and \( \zeta(0) = 0 \) is an increasing homeomorphism of \( \mathbb{R}^+ \) onto itself. Then, to conclude, we just repeat (with minor modifications) the proof already given by Manásevich and Mawhin in [10] Example 2.2 for the vector \( p \)-Laplacian, that is

\[
\langle \phi(x_1) - \phi(x_2), x_1 - x_2 \rangle =
\gamma(|x_1||x_1|^2 + \gamma(|x_2||x_2|^2 - \gamma(|x_1||x_1|)\langle x_1, x_2 \rangle - \gamma(|x_2||x_2|)\langle x_1, x_2 \rangle
\geq \gamma(|x_1||x_1|^2 + \gamma(|x_2||x_2|^2 - \gamma(|x_1||x_1||x_2| - \gamma(|x_2||x_2|)\langle x_1, x_2 \rangle
= \langle \zeta(|x_1|) - \zeta(|x_2|) \rangle (|x_1| - |x_2|) \geq 0.
\]

Therefore, we have that \( \langle \phi(x_1) - \phi(x_2), x_1 - x_2 \rangle = 0 \) implies \( |x_1| = |x_2| \). Then, either \( x_1 = x_2 = 0 \) or \( |x_1| \neq 0 \) and \( \langle \phi(x_1) - \phi(x_2), x_1 - x_2 \rangle = \gamma(|x_1||x_1|^2 - \gamma(|x_2||x_2|)\langle x_1, x_2 \rangle \), so that we conclude again that \( x_1 = x_2 \). Hence (H1) is proved.

On the other hand, we claim that there are homeomorphisms \( \phi \) of the form (5.7) which do not satisfy condition (H1). Before presenting our example, we first introduce a class of homeomorphisms satisfying (5.7) which strictly includes the \( p \)-Laplacian class.

Let \( A: S^{m-1} \to \mathbb{R}^n_0 \) be a continuous map, where \( S^{m-1} = \partial B(0,1) \) is the \((m - 1)\)-dimensional sphere in the Euclidean space \( \mathbb{R}^m \). Let also \( p > 1 \) be a fixed real number. We define

\[
\phi(\xi) := |\xi|^{p-2}A \left( \frac{\xi}{|\xi|} \right) \xi, \quad \text{if} \ \xi \in \mathbb{R}^m \setminus \{0\}, \quad \phi(0) = 0, \quad (5.13)
\]
which is of the form (5.7) for \( A(\xi) := |\xi|^{p-2}A(\xi/|\xi|) \). It is straightforward to check that maps of the form (5.13) are one-to-one, surjective and continuous, therefore, by Brouwer invariance of domain theorem, are homeomorphisms of \( \mathbb{R}^m \).

We give now an example of a planar homeomorphism of the form (5.13) which does not satisfy condition (H1). It is not difficult to extend the example to any dimension \( m \geq 2 \). For simplicity, we restrict to the case \( p = 2 \). First of all, we observe that, given two nontrivial vectors \( x_1 \neq x_2 \) and for \( v_i := x_i/|x_i| \) (\( i = 1, 2 \)), we have

\[
\langle \phi(x_1) - \phi(x_2), x_1 - x_2 \rangle =
\langle A(v_1)x_1 - A(v_2)x_2, x_1 - x_2 \rangle
= A(v_1)|x_1|^2 + A(v_2)|x_2|^2 - (A(v_1) + A(v_2))\langle x_1, x_2 \rangle
= A(v_1)|x_1|^2 + A(v_2)|x_2|^2 - (A(v_1) + A(v_2))|x_1||x_2|\cos \beta.
\]

The inner product is clearly positive when \( \langle x_1, x_2 \rangle = 0 \). We show now how to find vectors where it can get negative values. We take as \( A: S^1 \to \mathbb{R}^n_0 \) any continuous map such that \( A(1) = 1 \) and \( A(e^{i\pi/4}) = 6 \). Then, for the vectors

\[
x_1 = (1,0), \quad x_2 = \rho (\sqrt{2}/2, \sqrt{2}/2), \quad \text{with} \ \rho = \frac{7\sqrt{2}}{24},
\]

36
the above formula (with $\beta = \pi/4$) yields
\[ \langle \phi(x_1) - \phi(x_2), x_1 - x_2 \rangle = -\frac{1}{48} < 0. \]

This shows the effectiveness of Theorem 3.4 and Theorem 4.4 which allow to extend Hartman-Knobloch theorem to a broader class of operators not included in [16, 25].

6 Concluding remarks

In this paper all the applications of the abstract results to differential systems have been considered in the context of vector fields which are globally defined on the Euclidean space $\mathbb{R}^m$ (cf. system (6.1)) or have an inverse that is globally defined (cf. (3.3)). However, there are some significant cases of maps which have as their natural domain/image an open (and possibly bounded) subset of $\mathbb{R}^m$. In the one-dimensional case, typical examples in this direction arise from the study of the mean curvature operator
\[ u \mapsto \frac{u'}{\sqrt{1 + (u')^2}} \]
or of the Minkowski operator
\[ u \mapsto \frac{u'}{\sqrt{1 - (u')^2}}, \]
which may be described by means of homeomorphisms $\phi: I \to J$, with $I = \mathbb{R}$ and $J = ]-1,1[$, or $I = ]-1,1[$ and $J = \mathbb{R}$, respectively (see, for instance, [3, 31] and the references therein). Higher dimensional versions of these operators are usually studied as well.

As already observed in Remark 3.1 and underlined many times along the paper, our abstract setting has been devised in order to deal with these general cases, too. Indeed, all our results in the previous sections could be reformulated (by suitably adapting the hypotheses) in terms of operators which are not defined on the whole space. Instead of discussing again with the needed details all the theorems and lemmas presented above, we just illustrate how to deal with the autonomous system
\[ (\phi(u'))' + k(t, u, u') = 0, \quad (6.1) \]
when $\phi$ (or $\phi^{-1}$) and $k$ are not defined on the whole space.

Let $\mathcal{A}, \mathcal{B}, \mathcal{G} \subseteq \mathbb{R}^m$ be nonempty open connected sets with $\mathcal{A}, \mathcal{B}$ containing the zero element $0_{\mathbb{R}^m}$. Let $k: [0, T] \times \mathcal{G} \times \mathcal{A} \to \mathbb{R}^m$ be an $L^1$-Carathéodory function and let $\phi: \mathcal{A} \to \phi(\mathcal{A}) = \mathcal{B}$ be a homeomorphism with $\phi(0) = 0$.

As before, we deal with the $T$-periodic problem associated with equation (6.1). We recall that a $T$-periodic solution of (6.1) is a continuously differentiable function $u: [0, T] \to \mathbb{R}^m$ such that $u(0) = u(T)$ and satisfying
- $u(t) \in \mathcal{G}$, for all $t \in [0, T]$;
- $u'(t) \in \mathcal{A}$, for all $t \in [0, T]$;
• $t \mapsto \phi(u'(t))$ is absolutely continuous;
• $u(t)$ satisfies (6.1), for a.e. $t \in [0,T]$.

Writing equation (6.1) as an equivalent cyclic feedback system in $\mathbb{R}^{2m}$ in the class $\mathcal{C}$
\[
\begin{cases}
u' = \phi^{-1}(y) \\y' = -k(t,u,\phi^{-1}(y))
\end{cases}
\] (6.2)
we can enter the setting presented in Section 2 with the choice of $X$, $Z$ and $L$ described at the beginning of Section 3 (with $n = 2$) and with $M$ the Nemytskii operator associated with the right-hand side of system (6.2). In this case, $M$ has as a domain the set of continuous pairs of functions $(x_1, x_2) \in X$ such that $x_1(t) \in \mathcal{G}$ and $x_2(t) \in \mathcal{B}$ for all $t \in [0,T]$.

We notice that our semi-abstract results such as Theorem 3.2 or Theorem 4.1 can be restated without changes (in view of the hypothesis $\Omega \subseteq \text{dom } M$, or $\Omega \subseteq \text{dom } \tilde{M}$, respectively). As a consequence, we can provide versions of Theorem 3.4 and Theorem 4.4 in this more general context. For these versions we must be careful in the choice of the open and bounded set $\mathcal{U} \subseteq \mathcal{C}^1_T$ considered in these theorems. Indeed, we need to check that
\[
\mathcal{U} \subseteq \{ u \in \mathcal{C}^1_T : u(t) \in \mathcal{G}, u'(t) \in \mathcal{A}, \forall t \in \mathbb{R}\}.
\]
In this framework we could also extend to higher dimensions the continuation theorem of Benevieri, do Ó and de Medeiros obtained in [2] in the one-dimensional case.

A Coincidence degree results for autonomous equations

In this appendix we deal with the $T$-periodic boundary value problem associated with the autonomous equation
\[
x' = f_0(x),
\] (A.1)
where $f_0 : \mathcal{A}_0 \to \mathbb{R}^d$ is a continuous function defined on the open (and not necessarily bounded) set $\mathcal{A}_0 \subseteq \mathbb{R}^d$.

Let $X : = C([0,T],\mathbb{R}^d)$ be the Banach space of the continuous functions from $[0,T]$ to $\mathbb{R}^d$, endowed with the sup-norm, and let $Z : = L^1([0,T],\mathbb{R}^d)$ be the space of integrable functions from $[0,T]$ to $\mathbb{R}^d$, endowed with the $L^1$-norm. Let $\text{dom } L \subseteq X$ be the set of absolutely continuous functions satisfying the periodic boundary condition $x(0) = x(T)$. We define the linear differential operator $L : \text{dom } L \to Z$ as
\[
(Lx)(t) := x'(t), \quad t \in [0,T],
\]
which is a Fredholm mapping of index zero.

Let
\[
\text{dom } M_0 := \{ x \in X : x(t) \in \mathcal{A}_0, \forall t \in [0,T] \}.
\]
We define $M_0 : \text{dom } M_0 \to Z$ as the Nemytskii operator induced by the function $f_0(s)$, namely
\[
(M_0u)(t) = f_0(u(t)), \quad t \in [0,T].
\]
With this position, the $T$-periodic boundary value problem associated with (A.1) can be written as an equivalent coincidence equation
\[ Lx = M_0 x, \quad x \in \text{dom } L \cap \text{dom } M_0. \]

In this context the following theorem holds.

**Theorem A.1.** Let $A_0 = \mathbb{R}^d$. Let $\Omega \subseteq X$ be an open bounded set. Assume that there is no $u \in \partial \Omega$ such that $u' = f_0(u)$. Then
\[ D_L(L - M_0, \Omega) = (-1)^d \deg_B(f_0, \Omega \cap \mathbb{R}^d, 0). \]

The above result was proved by Capietto, Mawhin and Zanolin in [5] using Mawhin’s coincidence degree and an approximation argument based on Kupka-Smale theorem. A generalization of Theorem A.1 to the neutral functional differential equation $\frac{d}{dt}(Dx_t) = g(x_t)$ was obtained by Bartsch and Mawhin in [1] using the topological degree for $S^1$-equivariant maps. The main result in the article of Bartsch and Mawhin (cf. [1, Theorem 1]) concerns a vector field defined on the whole space, however its proof is based on a “local” result [1, Theorem 2], which, if adapted to our situation, allows to prove easily the following version of Theorem A.1.

**Theorem A.2.** Let $\Omega \subseteq X$ be an open bounded set with $\overline{\Omega} \subseteq \text{dom } M_0$. Assume that there is no $u \in \partial \Omega$ such that $u' = f_0(u)$. Then
\[ D_L(L - M_0, \Omega) = (-1)^d \deg_B(f_0, \Omega \cap \mathbb{R}^d, 0). \]

The next theorem is a generalization of the above results, dealing with an open (possibly unbounded) set $\Omega \subseteq X$.

**Theorem A.3.** Let $\Omega \subseteq \text{dom } M_0$ be an open (possibly unbounded) set such that the set of the ($T$-periodic) solutions of (6.1) in $\Omega$ is a compact subset of $\Omega$. Then
\[ D_L(L - M_0, \Omega) = (-1)^d \deg_B(f_0, \Omega \cap \mathbb{R}^d, 0). \]

**Proof.** Let $K$ be the set of the ($T$-periodic) solutions of (6.1) in $\Omega$. We stress that $K$ is a compact subset of $\Omega$ (by hypothesis). Then, we can find an open bounded set $\Omega_0$ such that $K \subseteq \Omega_0 \subseteq \text{cl}(\Omega_0) \subseteq \Omega$ and so, by the excision, $D_L(L - M_0, \Omega) = D_L(L - M_0, \Omega_0)$. Since there is no $u \in \partial \Omega_0$ such that $u' = f_0(u)$, we apply Theorem A.2 and get $D_L(L - M_0, \Omega_0) = (-1)^d \deg_B(f_0, \Omega_0 \cap \mathbb{R}^d, 0)$. We conclude observing that $\deg_B(f_0, \Omega_0 \cap \mathbb{R}^d, 0) = \deg_B(f_0, \Omega \cap \mathbb{R}^d, 0)$ (due to the excision property and the fact that $K \subseteq \Omega_0 \subseteq \Omega$).
