Abstract

In the paper [Dr3] V. Drinfeld formulated a number of problems in quantum group theory. In particular, he raised the question about the existence of a universal quantization for Lie bialgebras, which arose from the problem of quantization of Poisson Lie groups. When the paper [KL] appeared Drinfeld asked whether the methods of [KL] could be useful for the problem of universal quantization of Lie bialgebras. This paper gives a positive answer to a number of Drinfeld's questions, using the methods and ideas of [KL]. In particular, we show the existence of a universal quantization. We plan to provide positive answers to most of the remaining questions in [Dr3] in the following papers of this series.

Introduction

The main result of this paper is a construction of a universal quantization for Lie bialgebras (see [Dr3] Section 1).

The paper consists of two parts. In the first part we construct the quantization of a finite dimensional Lie bialgebra. In the second part we generalize this result to the infinite-dimensional case. The construction in the first part consists of three steps.

1) Given a finite dimensional Lie bialgebra \( \mathfrak{a} \) over a field \( k \) of characteristic zero, we construct the double \( \mathfrak{g} \) of \( \mathfrak{a} \). Our definition of the double coincides with the one in [Dr1]. We consider the category \( \mathcal{M} \) whose objects are \( \mathfrak{g} \)-modules and \( \text{Hom}_{\mathcal{M}}(U,W) = \text{Hom}_\mathfrak{g}(U,W)[[h]] \). For any associator \( \Phi \) ([Dr2, Dr4]) we define a structure of a braided monoidal category on \( \mathcal{M} \), as in [Dr2].

2) We construct Verma modules \( M_+, M_- \) over \( \mathfrak{g} \), and use them to construct a fiber functor from \( \mathcal{M} \) to the tensor category of topologically free \( k[[h]] \) modules: \( F(V) = \text{Hom}_{\mathcal{M}}(M_+ \otimes M_-, V) \). According to the categorical yoga, the existence of such a functor implies the existence of a (topological) Hopf algebra \( H \) isomorphic to \( U(\mathfrak{g})[[h]] \) such that the tensor category \( \mathcal{M} \) is equivalent to the category of representations of \( H \). We show that \( H \) is isomorphic, as a topological algebra, to \( U(\mathfrak{g})[[h]] \), where \( U(\mathfrak{g}) \) is the universal enveloping algebra of the Lie algebra \( \mathfrak{g} \).
3) We construct Hopf subalgebras $H_{\pm}$ of $H$ and show that $H_{+}$ is a quantization of $\mathfrak{a}$ and that the algebra $H$ is the quantum double of the Hopf algebra $H_{+}$.

**Remark.** We do not expect the existence of a quantization of any Lie bialgebra $\mathfrak{a}$ which is isomorphic to $U(\mathfrak{a})[[h]]$ as a topological algebra.

As an application of our techniques, we prove that any classical $r$-matrix $r$ over an associative algebra $A$ ($r \in A \otimes A$) can be quantized. In other words, there exists a quantum $R$-matrix $R \in A \otimes A[[h]]$ such that $R = 1 + hr$. We also show that $R$ is unitary ($R^{21}R = 1$) if $r$ is unitary ($r^{21} = -r$). This answers questions in Section 3 of [Dr3]. As another application, we show the existence of the quantization of a quasitriangular Lie bialgebra $\mathfrak{a}$ (not necessarily finite dimensional) such that the obtained quantized universal enveloping algebra has a quasitriangular structure and is isomorphic to $U(\mathfrak{a})[[h]]$ as a topological algebra, which solves questions in Section 4 of [Dr3].

The construction of quantization given in Part I has two drawbacks. First, it does not work literally for infinite dimensional Lie bialgebras. Second, it does not allow to prove functoriality and universality of quantization. Therefore, in Part II we slightly modify the construction, which puts the results of the first part in a more general setting. Now we consider arbitrary Lie bialgebras, not necessarily finite dimensional. In this case the double $\mathfrak{g}$ of $\mathfrak{a}$ can also be constructed, but it carries a nontrivial topology if $\text{dim} \mathfrak{a} = \infty$. Instead of the category of all $\mathfrak{g}$-modules, we now consider the category $\mathcal{M}^e$ whose objects are equicontinuous $\mathfrak{g}$-modules, which are topological $\mathfrak{g}$-modules satisfying certain conditions. On this category, we define a braided monoidal structure analogously to the finite-dimensional case. We construct Verma modules $M_{+}, M_{-}$ over $\mathfrak{g}$ analogously to the finite-dimensional case. The module $M_{-}$ is equicontinuous. The module $M_{+}$, in general, is not equicontinuous, but the module $M_{+}^*$, dual to $M_{+}$ in an appropriate topology, is an equicontinuous $\mathfrak{g}$-module. Using $M_{-}$ and $M_{+}^*$, we define a fiber functor from $\mathcal{M}^e$ to the category of topological $k[[h]]$-modules, by $F(V) = \text{Hom}_{\mathcal{M}^e}(M_{-}, M_{+}^* \otimes V)$. Since the module $M_{+}$ is not always equicontinuous, this functor is not always representable in $\mathcal{M}^e$. We define a tensor structure on $F$ similarly to the finite dimensional case, and show that if $\mathfrak{g}$ is finite dimensional, the functors obtained in the first and second parts of the paper are isomorphic as tensor functors.

Next, we consider the algebra $H = \text{End}F$. It is a topological algebra over $k[[h]]$ with a “coproduct” $\Delta$, which maps $H$ into a completion of $H \otimes H$, but not necessarily in $H \otimes H$.

Finally, we construct a subalgebra $H_{+}$ of $H$ such that $\Delta(H_{+}) \subset H_{+} \otimes H_{+}$. This is a quantized universal enveloping algebra which is a quantization of $\mathfrak{a}$. For finite dimensional $\mathfrak{a}$, this quantization is isomorphic to the one obtained in the first part.

At the end of the paper we settle Drinfeld’s question of the existence of a universal quantization of Lie bialgebras by showing that the quantization obtained in the second part of the paper is universal. In Drinfeld’s language this means that the product and coproduct in the quantized algebra express in terms of acyclic tensor calculus via the commutator and cocommutator. This result implies that our quantization of Lie bialgebras is a functor from the category of Lie bialgebras to the category of topological Hopf algebras. It also shows that our quantizations of classical $r$-matrices, unitary $r$-matrices, and quasitriangular Lie bialgebras are universal and functorial. Thus we answer positively the corresponding questions of Drinfeld [Dr3].

**Remarks.** 1. The material of Part I does not seem sufficient for proving the
universality and functoriality. In fact, during the computation of the $h^2$-term of
multiplication in $U_h(\mathfrak{a})$, using the method of Part I, one gets non-acyclic expressions,
which cancel at the end of computation. Thus, the generalization to the infinite-
dimensional case is essential for the proof of functoriality, even for finite-dimensional
Lie bialgebras.

2. Most of the results of the paper could be formulated and proved over the ring
$k[[h]]/(h^N)$ rather than $k[[h]]$, and then the results over $k[[h]]$ could be obtained as
a limit. The only problem arises with the notions of the dual quantized universal
enveloping algebra and the quantum double, which collapse over $k[[h]]/(h^N)$. This
is why we chose to work over $k[[h]]$.

In fact, it is easy to see that the main results of the paper hold in a more general
setting than stated. Namely, one can take the Lie bialgebra $\mathfrak{a}$ to be “dependent on
$h$”, i.e. to be a Lie bialgebra over the ring $k[[h]]$, which is topologically free as a
$k[[h]]$-module. The universal acyclic formulas for quantization whose existence is
shown in Section 10 are well defined for this case, and define a functor $\mathfrak{a} \to U_h(\mathfrak{a})$,
from the category of Lie bialgebras over $k[[h]]$ which are topologically free as $k[[h]]$-
modules to the category of quantized universal enveloping algebras. In the second
paper of this series we will show that this functor is in fact an equivalence of
categories.

Moreover, it is easy to see that the acyclic formulas of Chapter 10 which express
the product and coproduct in $U_h(\mathfrak{a})$ in terms of commutator $[,]$ and cocommutator
$\delta$ of $\mathfrak{a}$, are in fact formal series in $[,]$ and $h\delta$ with coefficients independent of $h$. This
allows to generalize the results even further. Namely, let $K$ be any local Artinian or
pro-Artinian algebra over $\mathbb{Q}$, and $I$ be the maximal ideal in $K$. Let $k = K/I$ (it is
a field of characteristic 0). Given a Lie bialgebra $\mathfrak{a}$ over $K$ which is (topologically)
free as a $K$-module and cocommutative modulo $I$. Then the quantization functor
of Chapter 10 is defined and assigns to $\mathfrak{a}$ a quantized universal enveloping algebra
$U_{\text{quant}}(\mathfrak{a})$ over $K$. In the second paper we will show that this is an equivalence of
categories between the category of Lie bialgebras over $K$ which are topologically
free as $K$-modules, and the category of quantized universal enveloping algebras over
$K$. In particular, if $K = k[[h]]$ then $U_{\text{quant}}(\mathfrak{a}) = U_h(\tilde{\mathfrak{a}})$, where $\tilde{\mathfrak{a}}$ is $\mathfrak{a}$ with the same
commutator and cocommutator $\delta_{\tilde{\mathfrak{a}}} = h^{-1}\delta_{\mathfrak{a}}$.

The third paper of this series is not written yet. Therefore we will only indicate
the topics which we are planning to present in this part. First of all, we plan to
consider the case of graded bialgebras with finite-dimensional homogeneous compo-
nents and to show that in this case our formal quantization defines a family of Hopf
algebras $H_h$, depending on a parameter $h \in k$. Our second goal is to prove that for
Kac-Moody bialgebras our quantization coincides with the quantum Kac-Moody
algebra. As another application of our techniques we plan to show how to define
a quantum analog of the Kac-Moody algebra for arbitrary symmetrizable Cartan
matrix (not necessarily integral) and show that for generic values of $q$ the ”size” of
the quantized algebra is the same as of the usual Kac-Moody algebra. This would
settle the questions in Section 8 of [Dr3].

Acknowledgements

The authors are pleased to thank Maxim Vybornov for useful conversations and
Dror Bar-Natan for discussions and information about associators. The authors
also want to thank the referee for many valuable suggestions. The first author was
Part I

1. Drinfeld category.

The definitions and statements of Sections 1.1, 1.2 can be found in [Dr1].

1.1. Lie bialgebras.

Throughout this paper, \( k \) denotes a field of characteristic zero. Let \( \mathfrak{a} \) be a Lie algebra over \( k \), and \( \delta \) be a linear map \( \delta : \mathfrak{a} \to \mathfrak{a} \otimes \mathfrak{a} \).

**Definition.** One says that the map \( \delta \) defines a Lie bialgebra structure on \( \mathfrak{a} \) if it satisfies two conditions:

(i) \( \delta \) is a 1-cocycle of \( \mathfrak{a} \) with coefficients in \( \mathfrak{a} \otimes \mathfrak{a} \), i.e.

\[
\delta([ab]) = [1 \otimes a + a \otimes 1, \delta(b)] + [\delta(a), 1 \otimes b + b \otimes 1];
\]

(ii) The map \( \delta^* : \mathfrak{a}^* \otimes \mathfrak{a}^* \to \mathfrak{a}^* \) dual to \( \delta \) is a Lie bracket on \( \mathfrak{a}^* \).

In this case \( \delta \) is called the cocommutator of \( \mathfrak{a} \).

If \( \mathfrak{a} \) is a finite dimensional Lie bialgebra then \( \mathfrak{a}^* \) is a Lie bialgebra as well. Namely, the commutator in \( \mathfrak{a}^* \) is dual to the cocommutator in \( \mathfrak{a} \), and the cocommutator in \( \mathfrak{a}^* \) is dual to the commutator in \( \mathfrak{a} \). If \( \mathfrak{a} \) is infinite-dimensional, then \( \mathfrak{a}^* \) is not in general a Lie bialgebra but is a topological Lie bialgebra. That is, \( \mathfrak{a}^* \) is a Lie algebra in the usual sense, but the cocommutator maps \( \mathfrak{a}^* \) into the completed tensor product \( \mathfrak{a}^* \otimes \mathfrak{a}^* \) and not necessarily into the usual tensor product \( \mathfrak{a}^* \otimes \mathfrak{a}^* \).

For any Lie bialgebra \( \mathfrak{a} \), the vector space \( \mathfrak{g} = \mathfrak{a} \oplus \mathfrak{a}^* \) has a natural structure of a Lie algebra. Namely, \( \mathfrak{a}, \mathfrak{a}^* \) are Lie subalgebras in \( \mathfrak{g} \) with bracket defined above, and commutator between elements of \( \mathfrak{a}, \mathfrak{a}^* \) is given by

\[
[a, b] = (\text{ad}^* a)b - (1 \otimes b)(\delta(a)), a \in \mathfrak{a}, b \in \mathfrak{a}^*;
\]

where \( \text{ad}^* \) denotes the coadjoint action. There is an invariant nondegenerate inner product on \( \mathfrak{g} \) given by \( \langle a + a', b + b' \rangle = a'(b) + b'(a), a, b \in \mathfrak{a}, a', b' \in \mathfrak{a}^* \). It is easy to show that (1.1) is the unique extension of the commutator from \( \mathfrak{a}, \mathfrak{a}^* \) to \( \mathfrak{g} \) for which the inner product \( <,> \) is ad-invariant.

1.2. Manin triples.

**Definition.** A triple \( (\mathfrak{g}, \mathfrak{g}_+, \mathfrak{g}_-) \), where \( \mathfrak{g} \) is a finite dimensional Lie algebra with a nondegenerate invariant inner product \( \langle, \rangle \), and \( \mathfrak{g}_+, \mathfrak{g}_- \) are isotropic Lie subalgebras, such that \( \mathfrak{g} = \mathfrak{g}_+ \oplus \mathfrak{g}_- \) as a vector space, is called a finite dimensional Manin triple. To every finite dimensional Lie bialgebra \( \mathfrak{a} \) one can associate the corresponding Manin triple \( (\mathfrak{g} = \mathfrak{a} \oplus \mathfrak{a}^*, \mathfrak{a}, \mathfrak{a}^*) \), where the Lie structure on \( \mathfrak{g} \) is as above. Conversely, if \( (\mathfrak{g}, \mathfrak{g}_+, \mathfrak{g}_-) \) is a finite dimensional Manin triple then \( \mathfrak{g}_+ \) (and \( \mathfrak{g}_- \)) is naturally a Lie bialgebra. Namely the pairing \( \langle, \rangle \) identifies \( \mathfrak{g}_+ \) with \( \mathfrak{g}_-^* \), so we can define \( \delta : \mathfrak{g}_+ \to \mathfrak{g}_+ \otimes \mathfrak{g}_+ \) to be the dual map to the commutator of \( \mathfrak{g}_- \). This map is a 1-cocycle of the Lie algebra \( \mathfrak{g}_+ \) with coefficients in the module \( \mathfrak{g}_+ \otimes \mathfrak{g}_+ \), so it defines a structure of a Lie bialgebra on \( \mathfrak{g}_+ \).

Thus, there is a one-to-one correspondence between finite dimensional Lie bialgebras and finite dimensional Manin triples.

If \( \mathfrak{a} \) is a Lie bialgebra then the Lie algebra \( \mathfrak{g} = \mathfrak{a} \oplus \mathfrak{a}^* \) also has a natural structure of a Lie bialgebra. Namely, the cocommutator on \( \mathfrak{g} \) is \( \delta^* = \delta_\alpha \oplus (-\delta_{\alpha}^*) \), where \( \delta_\alpha, \delta_{\alpha}^* \) are the cocommutators of \( \mathfrak{a}, \mathfrak{a}^* \).
The 1-cocycle $\delta_a$ is the coboundary of an element in $g \otimes g$. Namely, if $r \in a \otimes a^* \subset g \otimes g$ is the canonical element corresponding to the identity operator $a \rightarrow a$, then $\delta_a = dr$, where $r$ is regarded as a 0-cochain of $g$ with coefficients in $g \otimes g$, and $d$ is the differential in the cochain complex; that is $\delta_a(x) = [x \otimes 1 + 1 \otimes x, r]$.

The Lie bialgebra $g$ is called the double of $a$.

Let $a$ be a Lie algebra, and $r \in a \otimes a$. The equation

\[(1.2) \quad [r_{12}, r_{13}] + [r_{12}, r_{23}] + [r_{13}, r_{23}] = 0\]

in $U(a)^{\otimes 3}$ is called the classical Yang-Baxter equation. It is easy to check that the canonical element $r$ satisfies this equation.

**Definition.** We say that a Lie bialgebra $a$ is quasitriangular if it is equipped with an element $r \in a \otimes a$ satisfying the classical Yang-Baxter equation, such that $\delta(a) = [a \otimes 1 + 1 \otimes a, r]$ for any $a \in a$ (i.e. $\delta$ is a coboundary of $r$).

For example, the double $g$ of any finite dimensional Lie bialgebra $a$ equipped with the canonical element $r$ is a quasitriangular Lie bialgebra.

1.3. **Associators.** Recall some notation and definitions from the theory of associators [Dr2,BN]. Let $T_n$ be the algebra over $k$ generated by elements $t_{ij}$, $1 \leq i, j \leq n$, $i \neq j$, with defining relations $t_{ij} = t_{ji}$, $[t_{ij}, t_{lm}] = 0$ if $i, j, l, m$ are distinct, and $[t_{ij}, t_{ik} + t_{jk}] = 0$.

Let $P_1, ..., P_n$ be disjoint subsets of $\{1, ..., m\}$. There exists a unique homomorphism $\rho_{P_1...P_n}: T_n \rightarrow T_m$ defined by

\[(1.3) \quad \rho_{P_1...P_n}(t_{ij}) = \sum_{p \in P_i, q \in P_j} t_{pq}.\]

For any $X \in T_n$, we denote $\rho_{P_1...P_n}(X)$ by $X_{P_1,...,P_n}$.

Let $\Phi \in T_3$. The relation

\[(1.4) \quad \Phi_{1,2,3,4}\Phi_{12,3,4} = \Phi_{2,3,4}\Phi_{1,23,4}\Phi_{1,2,3}\]

in $T_4[[h]]$ (=relation (1.2) in [Dr2]) is called the pentagon relation.

Let $B = e^{ht_{12}/2} \in T_2[[h]]$. The relations

\[(1.5) \quad B_{12,3} = \Phi_{3,1,2}B_{1,3}\Phi_{1,3,2}^{-1}B_{2,3}\Phi_{1,2,3}, \quad B_{1,23} = \Phi_{2,3,1}^{-1}B_{1,3}\Phi_{2,1,3}B_{1,2}\Phi_{1,2,3}^{-1}.\]

in $T_3[[h]]$ (=relations (3.9a),(3.9b) in [Dr2]) are called the hexagon relations.

The element $\Phi$ is called an associator if it satisfies the pentagon and hexagon relations.

For $k = \mathbb{C}$, an example of an associator is the Drinfeld associator $\Phi_{KZ}$ obtained from the KZ equations, as explained in [Dr2].

The following theorem about associators is due to Drinfeld ([Dr4], Theorem A').

**Theorem 1.1.** There exists an associator defined over $\mathbb{Q}$.

This theorem implies that there exists an associator defined over any field $k$ of characteristic zero. From now on we will fix such an associator $\Phi$.

1.4. **Drinfeld category.**
Let $\mathfrak{g}$ be a Lie algebra over $k$, and $\Omega \in S^2\mathfrak{g}$ be a $\mathfrak{g}$-invariant element.

We will be mostly interested in the case when $\mathfrak{g}$ belongs to a finite dimensional Manin triple $(\mathfrak{g}, \mathfrak{g}_+, \mathfrak{g}_-)$, and $\Omega = \sum_i g_i \otimes g^i$, where $\{g_i\}$ is a basis of $\mathfrak{g}$, and $\{g^i\}$ is the dual basis to $\{g_i\}$ with respect to the invariant inner product on $\mathfrak{g}$. In this case the element $\Omega$ is called the Casimir element.

Let $\mathcal{M}$ denote the category whose objects are $\mathfrak{g}$-modules, and $\text{Hom}_\mathcal{M}(U, W) = \text{Hom}_\mathfrak{g}(U, W)[[h]]$. This is a $k[[h]]$-linear additive category. For brevity we will later write $\text{Hom}$ for $\text{Hom}_\mathcal{M}$.

Drinfeld [Dr2] defined a structure of a braided monoidal category on $\mathcal{M}$ as follows.

For any $V_1, V_2, V_3 \in \mathcal{M}$, consider a homomorphism $\theta : T_3[[h]] \to \text{End}(V_1 \otimes V_2 \otimes V_3)$ by $\theta(t_{ij}) = \Omega_{ij}$, and define $\Phi_{V_1 V_2 V_3} = \theta(\Phi)$.

For any $V_1, V_2 \in \mathcal{M}$, define $V_1 \otimes V_2 \in \mathcal{M}$ to be the usual tensor product of $V_1, V_2$ and the associativity morphism to be $\Phi_{V_1 V_2 V_3}$, regarded as an element of $\text{Hom}((V_1 \otimes V_2) \otimes V_3, V_1 \otimes (V_2 \otimes V_3))$. For any $V_1, V_2 \in \mathcal{M}$, introduce the braiding $\beta_{V_1 V_2} : V_1 \otimes V_2 \to V_2 \otimes V_1$ by the formula $\beta = s \circ e^{h\Omega/2}$, where $s$ is the permutation.

It follows from relations (1.4), (1.5) that the morphisms $\Phi_{V_1 V_2 V_3}$ and $\beta_{V_1 V_2}$ define the structure of a braided monoidal category on $\mathcal{M}$ (see [Dr2]).

2. The fiber functor.

2.1. The category of topologically free $k[[h]]$-modules.

Let $V$ be a vector space over $k$. Then the space $V[[h]]$ of formal power series in $h$ with coefficients in $V$ has a natural structure of a topological $k[[h]]$-module. We call a topological $k[[h]]$-module topologically free if it is isomorphic to $V[[h]]$ for some $V$.

Let $\mathcal{A}$ be the category of topologically free $k[[h]]$-modules, where morphisms are continuous $k[[h]]$-linear maps. It is an additive category. Define the tensor structure on $\mathcal{A}$ as follows: for $V, W \in \mathcal{A}$ define $V \otimes W$ to be the projective limit of the $k[[h]]/h^n$-modules $(V/h^n V) \otimes (W/h^n W)$ as $n \to \infty$.

Let $\text{Vect}$ be the category of vector spaces. We have the functor of extension of scalars, $V \mapsto V[[h]]$, acting from $\text{Vect}$ to $\mathcal{A}$. This functor respects the tensor product, i.e. $(V \otimes W)[[h]]$ is naturally isomorphic to $V[[h]] \otimes W[[h]]$. The category $\mathcal{A}$ equipped with the functor $\otimes$ is a symmetric monoidal category.

If $X \in \mathcal{A}$ then $X^* = \text{Hom}_\mathcal{A}(X, k[[h]])$ is a topologically free $k[[h]]$-module. The assignment $X \to X^*$ is a contravariant functor from $\mathcal{A}$ to itself.

2.2. The forgetful functor.

Let $(\mathfrak{g}, \mathfrak{g}_+, \mathfrak{g}_-)$ be a finite dimensional Manin triple, $\Omega \in S^2\mathfrak{g}$ be the Casimir element associated to the inner product $\langle , \rangle$ on $\mathfrak{g}$, and $\mathcal{M}$ be the Drinfeld category associated to $\mathfrak{g}$.

Let $F : \mathcal{M} \to \mathcal{A}$ be the functor given by $F(M) = \text{Hom}(U(\mathfrak{g}), M)$, where $U(\mathfrak{g})$ is regarded as a left $\mathfrak{g}$-module. This functor is naturally isomorphic to the “forgetful” functor which assigns to every $\mathfrak{g}$-module $M$ the $k[[h]]$-module $M[[h]]$. The isomorphism between these two functors is given by the assignment $f \in F(M) \to f(1) \in M[[h]]$.

2.3. The Verma modules.

Consider the Verma modules $M_+ = \text{Ind}_{\mathfrak{g}_+}^\mathfrak{g} 1$, $M_- = \text{Ind}_{\mathfrak{g}_-}^\mathfrak{g} 1$ (here 1 denotes the trivial 1-dimensional representation). By the Poincare-Birkhoff-Witt theorem, the product in $U(\mathfrak{g})$ defines linear isomorphisms $U(\mathfrak{g}_+) \otimes U(\mathfrak{g}_-) \to U(\mathfrak{g})$, and
1 \rightarrow 1_+ \otimes 1_- extends to an isomorphism of \(g\)-modules
\(\phi : U(g) \rightarrow M_+ \otimes M_-\).

Lemma 2.1 implies that the functor \(F\) can be identified with the functor \(V \rightarrow \text{Hom}(M_+ \otimes M_-, V)\). This definition of \(F\) will be used from now on.

2.4. Tensor structure on the functor \(F\).

Let \((\mathcal{C}, \otimes)\) be a monoidal category, \(\Phi\) be the associativity constraint in \(\mathcal{C}\), and \(1\) be the identity object in \(\mathcal{C}\). For simplicity we assume that \(1 \otimes X = X \otimes 1 = X\) for any object \(X \in \mathcal{C}\), and the functorial isomorphisms \(X \otimes X \otimes 1, X \rightarrow 1 \otimes X\) the are identity morphisms.

Let \(F : \mathcal{C} \rightarrow \mathcal{A}\) be a functor such that \(F(1) = k[[h]]\).

Definition. By a tensor structure on the functor \(F\) one means a functorial isomorphism \(J_{VW} : F(V) \otimes F(W) \rightarrow F(V \otimes W)\) satisfying the associativity identity
\(F(\Phi_{VWU})J_{V \otimes WU} \circ (J_{VW} \otimes 1) = J_{V,W \otimes U} \circ (1 \otimes J_{WU})\), such that for any object \(V J_{V1} = J_{1V} = 1\). A functor equipped with a tensor structure is called a tensor functor.

Now we describe a tensor structure on the functor \(F\) constructed in Section 2.2.

For any \(v \in F(V), w \in F(W)\) define \(J_{VW}(v \otimes w)\) to be the composition of morphisms:

\[
\begin{align*}
M_+ \otimes M_- & \xrightarrow{i_+ \otimes i_-} (M_+ \otimes M_+) \otimes (M_- \otimes M_-) \xrightarrow{\text{associativity morphism}} \\
& \quad \rightarrow (M_+ \otimes (M_+ \otimes M_-)) \otimes M_- \xrightarrow{(1 \otimes \beta_{23}) \otimes 1} \\
& \quad \rightarrow (M_+ \otimes (M_- \otimes M_+)) \otimes M_- \xrightarrow{\text{associativity morphism}} \\
& \quad \rightarrow (M_+ \otimes M_-) \otimes (M_+ \otimes M_-) \xrightarrow{\nu \otimes \nu} V \otimes W,
\end{align*}
\]

where \(\beta_{23}\) denotes the braiding \(\beta\) acting in the second and third components of the tensor product.

It is clear from this definition that all combinatorial complexity of the morphism \(J\) comes from the arrows “associativity morphism” which involve associators.

The arrows “associativity morphism” make the problem of checking various identities for \(J\) (for example, the associativity identity) rather tedious. To avoid this, we can use MacLane’s theorem, which says that any monoidal category is equivalent to a strict one. Namely, when we check identities between morphisms in the category, we will assume that the category \(\mathcal{M}\) is replaced with an equivalent strict
monoidal category and ignore associativity morphisms. For example, the definition of $J$ will look as follows:

$$J_{VW}(v \otimes w) = (v \otimes w) \circ (1 \otimes \beta_{23} \otimes 1) \circ (i_+ \otimes i_-).$$

However, when we do computations with vectors in modules from $\mathcal{M}$, it is important to pay attention to brackets, since different positions of brackets are related with each other by the associator.

**Proposition 2.2.** The maps $J_{VW}$ are isomorphisms and define a tensor structure on the functor $F$.

**Proof.** It is obvious that $J_{VW}$ is an isomorphism since it is an isomorphism modulo $h$. It is also clear that $J_{V1} = J_{1V} = 1$. Thus the only thing we need to check is the associativity identity $J_{V \otimes W,U} \circ (J_{VW} \otimes 1) = J_{V,W \otimes U} \circ (1 \otimes J_{WU})$. To prove this equality, we need the following result.

**Lemma 2.3** $(i_+ \otimes 1) \circ i_+ = (1 \otimes i_+) \circ i_+$ in Hom$(M_+, M_+^{\otimes 3})$.

**Proof.** We prove the identity for $i_+$. The identity for $i_-$ is proved in the same way.

We need to show that for any vector $x \in M_+$

$$\Phi \cdot (i_+ \otimes 1)i_+x = (1 \otimes i_+)i_+x. \quad (2.2)$$

Since comultiplication in $U(g_-)$ is coassociative, i.e. $(i_+ \otimes 1)i_+x = (1 \otimes i_+)i_+x$, it is sufficient to show that the associator $\Phi$ is the identity on the image of $(i_+ \otimes 1)i_+$. Because $\Phi$ is $g$-invariant, it is enough to show that $\Phi \cdot (i_+ \otimes 1)i_+1_+ = (1 \otimes 1)i_+1_+$, i.e.

$$\Phi \cdot (1_+ \otimes 1_+ \otimes 1_+) = 1_+ \otimes 1_+ \otimes 1_+. \quad (2.3)$$

Since the subalgebras $g_+, g_-$ are isotropic, the operators $\Omega_{12}, \Omega_{23}$ annihilate the vector $1_+ \otimes 1_+ \otimes 1_+$. Thus, equation (2.3) follows from the definition of $\Phi$. $\square$

Now we can finish the proof of the proposition. Let $\psi_1, \psi_2 : M_+ \otimes M_- \rightarrow (M_+ \otimes M_-)^{\otimes 3}$ be the morphisms defined by

$$\psi_1 = (1 \otimes \beta_{23} \otimes 1 \otimes 1 \otimes 1) \circ (i_+ \otimes i_- \otimes 1 \otimes 1) \circ (1 \otimes \beta_{23} \otimes 1) \circ (i_+ \otimes i_-), \quad (2.4)$$

$$\psi_2 = (1 \otimes 1 \otimes 1 \otimes \beta_{45} \otimes 1) \circ (1 \otimes 1 \otimes i_+ \otimes i_-) \circ (1 \otimes \beta_{23} \otimes 1) \circ (i_+ \otimes i_-),$$

Then for any $v \in F(V), w \in F(W), u \in F(U)$ we have

$$J_{V \otimes W,U}(J_{VW} \otimes 1)(v \otimes w \otimes u) = (v \otimes w \otimes u) \circ \psi_1,$$

$$J_{V,W \otimes U}(1 \otimes J_{WU})(v \otimes w \otimes u) = (v \otimes w \otimes u) \circ \psi_2.$$

Therefore, to prove the proposition, it is sufficient to show that $\psi_1 = \psi_2$.

To prove this equality, we observe that the functoriality of the braiding implies the identities

$$\begin{align*}
(i_+ \otimes i_- \otimes 1 \otimes 1) \circ (1 \otimes \beta_{23} \otimes 1) &= (1 \otimes \beta_{3,45} \otimes 1) \circ (i_+ \otimes 1 \otimes i_- \otimes 1), \\
(1 \otimes 1 \otimes i_+ \otimes i_-) \circ (1 \otimes \beta_{23} \otimes 1) &= (1 \otimes \beta_{23,4} \otimes 1) \circ (1 \otimes i_+ \otimes 1 \otimes i_-)
\end{align*} \quad (2.5)$$
which follows directly from the braiding axioms. □

Using Lemma 2.3 and identities (2.5), we reduce the statement $\psi_1 = \psi_2$ to the identity

\[(2.6) \quad (1 \otimes \beta_{23} \otimes 1 \otimes 1 \otimes 1) \circ (1 \otimes \beta_{3,45} \otimes 1) = (1 \otimes 1 \otimes 1 \otimes 1) \circ (1 \otimes \beta_{23,4} \otimes 1),\]

which follows directly from the braiding axioms. □

We call the functor $F$ equipped with the tensor structure $J$ the fiber functor.

3. Quantization of the double of a Lie bialgebra.

3.1. Topological Hopf algebras.

Let $A$ be an algebra over $k[[h]]$ with unit. Let $I$ be a proper two-sided ideal in $A$ such that $h \in I$. This ideal gives rise to a translation invariant topology on $A$ such that $\{I^n, n \geq 0\}$ is a basis of neighborhoods of 0. We will call $A$ a topological algebra if $A$ is complete in this topology, and $A/h^N A$ is a free $k[h]/(h^N)$-module for each $N \geq 1$.

Let $A, B$ be two topological algebras, $I, J$ be the corresponding ideals. Define $A \otimes B$ to be the projective limit of algebras $A/I^n \otimes_{k[[h]]/h^n} B/J^n$ as $n \to \infty$. Then $A \otimes B$ is also a topological algebra, with topology defined by the ideal $I \otimes B + A \otimes J$.

We say that a topological algebra $A$ is a topological Hopf algebra if it is equipped with comultiplication $\Delta : A \to A \otimes A$, the counit $\varepsilon : A \to k[[h]]$, and the antipode $S : A \to A$, which are $k[[h]]$-linear, continuous, and satisfy the standard axioms of a Hopf algebra. Note that an infinite dimensional topological Hopf algebra may not be literally a Hopf algebra because the image of comultiplication may not belong to the algebraic tensor square of $A$.

Topological algebras and Hopf algebras over $k$ are defined similarly.

If $A$ is a topological algebra or Hopf algebra over $k[[h]]$ then $B = A/hA$ is a topological algebra, respectively Hopf algebra, over $k$. In such a case we say that $A$ is a formal deformation of $B$. In particular, if $B = U(\mathfrak{g})$ with discrete topology, where $\mathfrak{g}$ is a Lie algebra, then $A$ is called a quantized universal enveloping algebra [Dr1].

The following definition is due to Drinfeld [Dr1].

**Definition.** Let $(\mathfrak{g}, \delta)$ be a Lie bialgebra. We say that a quantized universal enveloping algebra $A$ is a quantization of $(\mathfrak{g}, \delta)$, or that $(\mathfrak{g}, \delta)$ is the quasiclassical limit of $A$, if

(i) $A/hA$ is isomorphic to $U(\mathfrak{g})$ as a Hopf algebra, and

(ii) For any $x_0 \in \mathfrak{g}$ and any $x \in A$ equal to $x_0 \mod h$ one has

$$h^{-1}(\Delta(x) - \Delta^{\text{op}}(x)) \equiv \delta(x_0) \mod h,$$

where $\Delta^{\text{op}}$ is the opposite comultiplication ($\Delta^{\text{op}} = s\Delta$).

3.2. The algebra of endomorphisms of the fiber functor.

Let $H = \text{End}(F)$ be the algebra of endomorphisms of the functor $F$. This algebra is naturally isomorphic to $U(\mathfrak{g})[[h]]$. Namely, the map $\alpha : U(\mathfrak{g})[[h]] \to H$ is defined on $x \in U(\mathfrak{g})$ by the formula $(\alpha(x)f)(y) = f(yx)$, where $f \in \text{Hom}(U(\mathfrak{g}), M)$, and is extended by linearity and continuity to $U(\mathfrak{g})[[h]]$. This map is an isomorphism of algebras. From now on we will make no distinction between $U(\mathfrak{g})[[h]]$ and $H$, identifying them by $\alpha$. 

9
Let $F^2 : \mathcal{M} \times \mathcal{M} \to \mathcal{A}$ be the bifunctor defined by $F^2(V,W) = F(V) \otimes F(W)$. It is clear that $\text{End}(F^2) = H \otimes H$.

The algebra $H$ has a natural comultiplication $\Delta : H \to H \otimes H$ defined by $\Delta(a)_{V,W}(v \otimes w) = J_{V,W}^{-1} a_{V \otimes W} J_{V,W}(v \otimes w)$, $a \in H$, $v \in F(V), w \in F(W)$ where $a_V$ denotes the action of $a$ in $F(V)$. We can also define the counit on $H$ by $\varepsilon(a) = a_1 \in k[[h]]$, where $1$ is the neutral object.

For any $V \in \mathcal{M}$, let $V^*$ be the dual space to $V$ (regarded as an object of $\mathcal{M}$), and let $\sigma_V : V^* \otimes V \to 1$ be the canonical pairing. We have a functorial isomorphism $\xi_V : F(V^*) \to F(V)^*$ defined by $\xi_V(v^*)(v) = F(\sigma_V)J_{V^*V}(v^* \otimes v), v \in F(V), v^* \in F(V^*)$. For any $a \in H$, let $S(a)_V = (\xi_V)^{-1} a_{V^*} \xi_V$ be a morphism $F(V)^* \to F(V)^*$. It is easy to show that the subspace $F(V) \subset F(V)^*$ is invariant under this morphism. The antipode $S : H \to H$ is defined by $S(a)_V = \widetilde{S(a)}_{V^*}|_{F(V)}$.

**Proposition 3.1.** The algebra $H$ equipped with $\Delta, \varepsilon, S$ is a topological Hopf algebra.

The proof is straightforward.

3.3. Explicit representation of comultiplication and antipode.

Let $\Delta_0 : U(g) \to U(g) \otimes U(g)$ be the standard coproduct. For any $V, W \in \mathcal{M}$, let $J^0_{V,W} : F(V) \otimes F(W) \to F(V \otimes W)$ be the morphism defined by the formula $J^0_{V,W}(v \otimes w)(x) = (v \otimes w)(\Delta_0(x)), x \in U(g), v \in F(V), w \in F(W)$. It is clear that $J_{V,W} \equiv J^0_{V,W}$ mod $h$.

Let $J \in U(g)^{\otimes 2}[h]$ be defined by the formula

\begin{equation}
J = (\phi^{-1} \otimes \phi^{-1}) \left( \Phi^{-1}_{1,2,3,4}(1 \otimes \Phi_{2,3,4})se^{h\Omega_{23}/2}(1 \otimes \Phi^{-1}_{2,3,4})\Phi_{1,2,3,4}(1_+ \otimes 1_+ \otimes 1_- \otimes 1_-) \right),
\end{equation}

where $\phi$ is the isomorphism of Lemma 2.1.

**Proposition 3.2.** For any $V, W \in \mathcal{A}, v \in F(V), w \in F(W)$ one has $J_{V,W}(v \otimes w) = J^0_{V,W} J(v \otimes w)$.

**Proof.** The statement follows from the definition (2.1) of $J_{V,W}$. □

**Lemma 3.3.** Let $a \in H$. Then

\begin{equation}
\Delta(a) = J^{-1}\Delta_0(a)J.
\end{equation}

**Proof.** The lemma follows from Proposition 3.2 and the identities $\Delta_0(a)_{V,W} = (J^0_{V,W})^{-1} a_{V \otimes W} J^0_{V,W}, \Delta(a)_{V,W} = J^{-1}_{V,W} a_{V \otimes W} J_{V,W}, a \in U(g)$. □

Now consider the explicit expression for the antipode. For any $V \in \mathcal{M}$ define the morphism $\xi^0_V : F(V^*) \to F(V)^*$ by $\xi^0_V(v^*)(v) = F(\sigma_V)J^0_{V^*V}(v^* \otimes v), v \in V, v^* \in V^*$. It is clear that $\xi_V \equiv \xi^0_V$ mod $h$.

Let $S_0 : U(g) \to U(g)$ be the usual antipode. Let $J = \sum_j x_j \otimes y_j, x_j, y_j \in U(g)[[h]]$ (the sum is finite modulo $h^n$ for any $n$). Define an element $Q \in U(g)[[h]]$ by $Q = \sum_j S_0(x_j)y_j$.

**Lemma 3.4.** Let $a \in H$. Then

\begin{equation}
S(a) = Q^{-1} S_0(a)Q.
\end{equation}
Proof. It follows from the definitions of $\xi_V$, $\xi_0$, and $Q$ that $\xi_V = \xi_0 V (Q)_{V^*}$. Thus the Lemma follows from the formulas $S(a)_V = (\xi^*_V)^{-1} a^*_V \xi^*_V |_{F(V)}$, $S_0(a)_V = (\xi^*_V)^{-1} a^*_V \xi^*_V |_{F(V)}$. □

Thus, we have proved the following result.

**Corollary 3.5.** Introduce a new comultiplication and antipode on the topological Hopf algebra $U(g)[[h]]$ by

$$(3.4) \quad \Delta(x) = J^{-1} \Delta_0(x) J, \quad S(x) = Q^{-1} S_0(x) Q,$$

where $\Delta_0, S_0$ are the usual comultiplication and antipode. Then $(U(g)[[h]], \Delta, S)$ is a topological Hopf algebra isomorphic to $H$.

We will denote the topological Hopf algebra $(U(g)[[h]], \Delta, S)$ by $U_h(g)$.

**Remark.** It is easy to see that according to the terminology of [Dr2], the element $J^{-1}$ is a twist that realizes an equivalence between the quasi-Hopf algebra $(U(g)[[h]], \Phi)$ and the Hopf algebra $U_h(g)$.

3.4. The quasiclassical limit of $U_h(g)$.

**Proposition 3.6.** The topological Hopf algebra $U_h(g)$ is a quantization of the Lie bialgebra $(g, \delta_g)$.

**Proof.** Take $a \in g \subset U_h(g)$. Let $\delta(a) \in U(g) \otimes U(g)$ be defined by the formula $\delta(a) = h^{-1}(\Delta(a) - \Delta^{op}(a)) \mod h$. To prove the proposition, we need to show that for any $a \in g$ one has $\delta(a) = \delta_g(a)$, where $\delta_g(a)$ is defined in Chapter 1.

It is easy to check the following identities:

$$(3.5) \quad e^{h\Omega/2} \equiv 1 + h\Omega/2 \mod h^2, \Phi \equiv 1 \mod h^2.$$

Let $\{g^+_j\}$ be a basis of $g_+$, $\{g^-_j\}$ be the dual basis of $g_-$, and $r = \sum_j g^+_j \otimes g^-_j$. Identities (3.1) and (3.5) imply that

$$(3.6) \quad J \equiv 1 + hr/2 \mod h^2.$$

Therefore, by Lemma 3.3,

$$(3.7) \quad \Delta(a) \equiv \Delta_0(a) + \frac{h}{2} [\Delta_0(a), r] \mod h^2.$$

Thus,

$$(3.8) \quad \Delta(a) - \Delta^{op}(a) \equiv \frac{h}{2} [\Delta_0(a), r - sr] \mod h^2.$$

Since $r + sr (= \Omega)$ is $g$-invariant, we obtain

$$(3.9) \quad \delta = dr = \delta_g,$$

Q.E.D. □

3.5. The quaitriangular structure on $U_h(g)$.

Define the element

$$(3.10) \quad R = (J^{op})^{-1} e^{h\Omega/2} J \in U_h(g) \otimes^2,$$

where $J^{op}$ is obtained from $J$ by permuting components. We call this element the universal R-matrix of $U_h(g)$. 

11
Proposition 3.7. $R$ defines a quasitriangular structure on $U_h(\mathfrak{g})$. That is, $R$ is invertible and

$$R \Delta = \Delta^{\text{op}} R,$$

(3.11)

Moreover, $R$ is a quantization of $r$, i.e.

$$R \equiv 1 + hr \mod h^2.$$  

(3.13)

Proof. Identity (3.13) follows from (3.5),(3.6) and the definition of $R$. This identity implies that $R$ is invertible.

One has

$$R \Delta (a) = (J^{\text{op}})^{-1} e^{h \Omega/2} J \Delta (a) = (J^{\text{op}})^{-1} e^{h \Omega/2} \Delta_0 (a) J = (J^{\text{op}})^{-1} \Delta_0 (a) e^{h \Omega/2} J = \Delta^{\text{op}} (a) (J^{\text{op}})^{-1} e^{h \Omega/2} J = \Delta^{\text{op}} (a) R,$$

(3.14)

which proves (3.11).

Now let us prove the first identity of (3.12). The second identity is proved analogously.

According to the definition of $R$, for any $V, W \in \mathcal{M}$, $v \in F(V)$, $w \in F(W)$, one has $R(v \otimes w) = s J^{-1} W_F (\beta_{VW}) J_{VW}$. Thus, for any $U \in \mathcal{M}$, $u \in F(U)$ one has

$$\Delta \otimes 1)(R)(v \otimes w \otimes u) = (J^{-1} W_v \otimes 1) R(J_{VW} \otimes 1)(v \otimes w \otimes u) =$$

(3.15)

$$s_{12,3} (1 \otimes J^{-1}_{VW}) J_{U,V \otimes W} F(\beta_{VW,U}) J_{V \otimes W,U} (J_{VW} \otimes 1)(v \otimes w \otimes u),$$

where $s_{12,3}$ is the permutation of the first two components with the third one. Using the braiding property $\beta_{V \otimes W,U} = (\beta_{VU} \otimes 1) \circ (1 \otimes \beta_{WU})$, the associativity of $J_{VW}$, and the obvious identities $J^{-1}_{U \otimes V,W} F(\beta_{VU} \otimes 1) J_{V \otimes U,W} = F(\beta_{VU}) \otimes 1$, $J^{-1}_{V, U \otimes W} F(1 \otimes \beta_{WU}) J_{V,W \otimes U} = 1 \otimes F(\beta_{WU})$, one finds that the right hand side of (3.15) equals to $R_{13} R_{23} (v \otimes w \otimes u)$, as desired. \hspace{1em} \square

4. Quantization of finite-dimensional Lie bialgebras.

Our purpose in this section is to represent the quasitriangular topological Hopf algebra $U_h(\mathfrak{g})$ as a quantum double of another topological Hopf algebra, $U_h(\mathfrak{g}_+)$. The topological Hopf algebra $U_h(\mathfrak{g}_+)$ will be a quantization of the Lie bialgebra $\mathfrak{g}_+$.

4.1. The algebras $U_h(\mathfrak{g}_\pm)$.

As we have seen, the fiber functor $F$ which we used to construct the quantum group $U_h(\mathfrak{g})$, is represented by the object $M_+ \otimes M_-$ of $\mathcal{M}$. Therefore, we have a homomorphism $\theta : \text{End}(M_+ \otimes M_-) \rightarrow \text{End}(F) = U_h(\mathfrak{g})$ defined by $\theta(a)v = v \circ a$, $v \in F(V), V \in \mathcal{M}, a \in \text{End}(M_+ \otimes M_-)$. 

12
**Lemma 4.1.** The map $\theta$ is an isomorphism.

**Proof.** The Lemma follows from Lemma 2.1. $\square$

Thus, we can identify $\text{End}(M_+ \otimes M_-)$ with $U_h(\mathfrak{g})$. From now on we make no distinction between them.

Now let us define the subalgebras $U_h(\mathfrak{g}_\pm) \subset U_h(\mathfrak{g})$.

Let $x \in F(M_+)$. Define the endomorphism $m_-(x)$ of $M_+ \otimes M_-$ to be the composition of the following morphisms in $M$: $m_-(x) = (x \otimes 1) \circ (1 \otimes i_-)$. This defines a linear map $m_- : F(M_+) \to U_h(\mathfrak{g})$. Denote the image of this map by $U_h(\mathfrak{g}_-)$. Let $m_0^0(x) \in U(\mathfrak{g}_-)$ be defined by the equation $x(1_+ \otimes 1_-) = m_0^0(x)1_+$. It is easy to show that $m_-(x) \equiv m_0^0(x) \mod h$, which implies that $m_-$ is an embedding.

A similar definition can be made for $x \in F(M_-)$. Define the endomorphism $m_+(x)$ of $M_+ \otimes M_-$ to be the composition of the following morphisms in $M$: $m_+(x) = (1 \otimes x) \circ (i_+ \otimes 1)$. This defines an injective linear map $m_+ : F(M_-) \to U_h(\mathfrak{g})$. Denote the image of this map by $U_h(\mathfrak{g}_+)$.

**Proposition 4.2.** $U_h(\mathfrak{g}_\pm)$ are subalgebras in $U_h(\mathfrak{g})$.

**Proof.** Let us give a proof for $U_h(\mathfrak{g}_-)$. The proof for $U_h(\mathfrak{g}_+)$ is analogous.

Using Lemma 2.3, we obtain

$$m_-(x) \circ m_-(y) = (x \otimes 1) \circ (1 \otimes i_-) \circ (y \otimes 1) \circ (1 \otimes i_-) =$$

$$= (x \otimes 1) \circ (y \otimes 1 \otimes 1) \circ (1 \otimes 1 \otimes i_-) \circ (1 \otimes i_-) =$$

$$(4.1) \quad = (x \otimes 1) \circ (y \otimes 1 \otimes 1) \circ (1 \otimes i_- \otimes 1) \circ (1 \otimes i_-) = (z \otimes 1) \circ (1 \otimes i_-),$$

where $z = x \circ (y \otimes 1) \circ (1 \otimes i_-) \in F(M_+)$. So by the definition we get $m_-(x) \circ m_-(y) = m_-(z)$. $\square$

Note that the algebra $U_h(\mathfrak{g}_-)$ is a deformation of the algebra $U(\mathfrak{g}_-)$. Indeed, we can define a linear isomorphism $\mu : U(\mathfrak{g}_-)[[h]] \to U_h(\mathfrak{g}_-)$ by $\mu(a)(1_+ \otimes 1_-) = a1_+$. This isomorphism has the property $\mu(ab) = \mu(a) \circ \mu(b) \mod h^2$, which follows from (3.5), but in general $\mu(ab) \neq \mu(a) \circ \mu(b)$.

The subalgebra $U_h(\mathfrak{g}_-)$ has a unit since it is a deformation of the algebra with unit $U(\mathfrak{g}_-)$. In fact, one can show that the unit equals to $\mu(1)$, $1 \in U(\mathfrak{g}_-)$. Similar statements apply to the algebra $U_h(\mathfrak{g}_+)$.

**Proposition 4.3.** The map $U_h(\mathfrak{g}_+) \otimes U_h(\mathfrak{g}_-) \to U_h(\mathfrak{g})$ given by $a \otimes b \to ab$ is an isomorphism.

**Proof.** The statement is true because it holds modulo $h$. $\square$

### 4.2. Polarization of the R-matrix.

Define the element $\tilde{R} \in U_h(\mathfrak{g}_+) \otimes U_h(\mathfrak{g}_-)$ by the identity

$$(4.2) \quad \tilde{R} \circ \beta^{-1} \circ (i_+ \otimes i_-) = \beta$$

in $\text{Hom}(M_+ \otimes M_-, M_- \otimes M_+)$. It is obvious that such an element is unique. It can be computed as follows.
Let \( \nu : M_\pm[[h]] \to U_h(\mathfrak{g}_\pm) \) be the linear isomorphism defined by the equation 
\( \nu(x(1_+ \otimes 1_-)) = m_\pm(x) \) for any \( x \in F(M_\pm) \). Let \( K \in U(\mathfrak{g}) \otimes^2[[h]] \) be given by 
(4.3) 
\[
K = (\phi^{-1} \otimes \phi^{-1})(\Phi_{1,2,34}(1 \otimes \Phi_{2,3,4}^-)se^{-h\Omega_{23}/2}(1 \otimes \Phi_{2,3,4}^-)\Phi_{1,2,34}(1_+ \otimes 1_+ \otimes 1_- \otimes 1_-)).
\]

Then it is easy to check, using (4.2), that
(4.4) 
\[
\hat{R} = (\nu \otimes \nu)(K^{-1}e^{h\Omega/2}(1_- \otimes 1_+)).
\]

**Proposition 4.4.** \( \hat{R} = R \).

**Proof.** According to (3.10), the R-matrix \( R \in U_h(\mathfrak{g}) \otimes U_h(\mathfrak{g}) \) is defined by the condition that for any \( V, W \in \mathcal{M} \) and \( v \in F(V), w \in F(W) \) one has the equality
(4.5) 
\[
R^{op}(v \otimes w) \circ \beta_{23} \circ (i_+ \otimes i_-) = \\
\beta \circ (w \otimes v) \circ \beta_{23} \circ (i_+ \otimes i_-)
\]
in \( \text{Hom}(M_+ \otimes M_-, V \otimes W) \).

By the functoriality of the braiding, \( R^{op}(v \otimes w) = \beta \circ R(w \otimes v) \circ \beta_{12,34}^{-1} \). Besides, \( \beta_{12,34} = \beta_{23} \circ \beta_{12} \circ \beta_{34} \circ \beta_{23} \). Substituting this into (4.5) and taking into account that \( \beta \circ i_\pm = i_\pm \), we get
(4.6) 
\[
R(w \otimes v) \circ \beta_{23}^{-1} \circ (i_+ \otimes i_-) = \\
(w \otimes v) \circ \beta_{23} \circ (i_+ \otimes i_-)
\]
in \( \text{Hom}(M_+ \otimes M_-, W \otimes V) \).

To show that \( R = \hat{R} \) we have to prove the identity
(4.7) 
\[
(1 \otimes \hat{R} \otimes 1) \circ (i_+ \otimes 1_+ \otimes 1_-) \circ \beta_{23}^{-1} \circ (i_+ \otimes i_-) = \\
\beta_{23} \circ (i_+ \otimes i_-)
\]
in \( \text{Hom}(M_+ \otimes M_-, M_+ \otimes M_- \otimes M_+ \otimes M_-) \).

Interchanging the order of factors on the left hand side of (4.7) and using Lemma 2.3, we can rewrite (4.7) in the form:
(4.8) 
\[
(1 \otimes \hat{R} \otimes 1) \circ \beta_{34}^{-1} \circ (1 \otimes i_+ \otimes i_- \otimes 1) \circ (i_+ \otimes i_-) = \\
\beta_{23} \circ (i_+ \otimes i_-)
\]
in \( \text{Hom}(M_+ \otimes M_-, M_+ \otimes M_- \otimes M_+ \otimes M_-) \).

It is obvious that identity (4.8) follows from is the definition of \( \hat{R} \). The proposition is proved. \( \square \)

**4.3. Subalgebras \( U_h(\mathfrak{g}_\pm) \) in terms of the R-matrix.**

Let \( U_h(\mathfrak{g}_\pm)^* = \text{Hom}_A(U_h(\mathfrak{g}_\pm), k[[h]]) \). Define \( k[[h]] \)-linear maps \( \rho_\pm : U_h(\mathfrak{g}_\pm)^* \to U_h(\mathfrak{g}_\pm) \), by \( \rho_+(f) = (1 \otimes f)(R) \), \( \rho_-(f) = (f \otimes 1)(R) \). Let \( U_\pm \) be the images of the maps \( \rho_\pm \), and \( \tilde{U}_\pm \) be the closures of the \( k[[h]] \)-subalgebras generated by \( U_\pm \).
Thus, the Lemma is true for $x$ if the coproduct is defined by $\Delta(x) = x + O(h)$. If $x$ has degree $\leq m$ with respect to the standard filtration in $U(\mathfrak{g}^+)$, then $t_x$ can be chosen in such a way that $h^mt_x \in \tilde{U}_+$. Therefore, $t_x = x + \mathcal{O}(h)$. The topology on $\tilde{U}_+$ is defined by $\Delta(x) = x + O(h)$.

Proof of the Lemma. It is clear that $1 \in \tilde{U}_+$ since $1 = \rho_+(\varepsilon)$. So we can set $t_1 = 1$.

Now consider the case $x \in \mathfrak{g}^+$. Let $f \in U_h(\mathfrak{g}^+)^*$ be any element such that $f(1) = 0$ and $f(a) = (x, a)$ for any $a \in \mathfrak{g}^-$ and $a \in U_h(\mathfrak{g}^-)$ such that $a = a \bmod h$. Then it follows from (3.13) that $\rho_+(f) = hx + \mathcal{O}(h^2)$. So we can let $t_x = h^{-1}\rho_+(f)$. Thus, the Lemma is true for $x \in \mathfrak{g}^+$.

Since $\tilde{U}_+$ is an algebra, the validity of the Lemma for $x \in \mathfrak{g}^+$ implies its validity for any $x \in U(\mathfrak{g}^+)$. □

Now we can prove the proposition. Let $T_0 \in U_h(\mathfrak{g}^+)$. Let $x_0 \in U(\mathfrak{g}^+)$ be the reduction of $T_0 \bmod h$. Then $T_0 - t_{x_0}$ is divisible by $h$, so we can consider $T_1 = h^{-1}(T_0 - t_{x_0})$ and repeat our procedure. This gives us a sequence $x_i \in U(\mathfrak{g}^+)$, and $T_0 = \sum_{m \geq 0} t_{x_m}h^m$. This shows that $T_0$ belongs to the h-adic completion of $\tilde{U}_+ \otimes k((h))$, as desired. □

Theorem 4.7. The subalgebras $U_h(\mathfrak{g}^\pm)$ are Hopf subalgebras in $U_h(\mathfrak{g})$.

Proof. The fact that $U_h(\mathfrak{g}^\pm)$ are closed under the comultiplication $\Delta$ follows from Proposition 4.5 and identities (3.12). The fact that $U_h(\mathfrak{g}^\pm)$ are closed under the antipode $S$ follows from Proposition 4.5 and the identity $(S \otimes 1)(R) = R^{-1}$, which holds in any quasitriangular Hopf algebra. □

Remark. In fact, it is possible to prove the following explicit formula for coproduct in $U_h(\mathfrak{g}^\pm)$: for any $x \in F(M_\pm)$

\begin{equation}
\Delta(m_\pm(x)) = (m_\pm \otimes m_\pm)(J_{M_\pm M_\pm}^{-1}(i_\pm \circ x)).
\end{equation}

The proof is a direct verification. A similar formula is contained in Proposition 9.3.

It is obvious that $U_h(\mathfrak{g}^+)/hU_h(\mathfrak{g}^+)$ is isomorphic to $U(\mathfrak{g}^+)$ as a Hopf algebra. Therefore, $U_h(\mathfrak{g}^+)$ is a quantized universal enveloping algebra. It follows from Proposition 3.6 that its quasiclassical limit is the Lie bialgebra $\mathfrak{g}^+$. Similar statements apply to $U_h(\mathfrak{g}^-)$.

4.4. Duality of quantized universal enveloping algebras and the quantum double.

The following general constructions can be found in [Dr1].

If $A$ is a quantized universal enveloping algebra then its dual $A^* = \text{Hom}_A(A, k[[h]])$ carries a natural structure of a topological algebra. Namely, for any $x, y \in A$,

$f, g \in A^* f g(x) = (f \otimes g)(\Delta(x))$, and the unit is $\varepsilon$. It can be shown that $A^*$ has a unique maximal ideal $I^*$, which is the kernel of the linear map $A \to k$ given by $f \to f(1) \bmod h$. The topology on $A^*$ is defined by the condition that $\{I^* n, n \geq 0\}$ is a basis of neighborhoods of zero. This implies that the topological algebras $(A \otimes A)^*$ and $A^* \otimes A^*$ are isomorphic.

The algebra $A^*$ has a natural structure of a topological Hopf algebra. Namely, the coproduct is defined by $\Delta(f)(x \otimes y) = f(xy)$, the counit is 1, and the antipode is
Proof. We only prove the first statement. The second one is proved analogously.

Let $A$ be any quantized universal enveloping algebra. Let $A^\ast$ be the dual algebra, and let $I^\ast$ be the maximal ideal in $A^\ast$. Consider the h-adic completion $A^\vee$ of the subalgebra $\sum_{n\geq 0} h^{-n}(I^\ast)^n$ in the algebra $A^\ast \otimes_k[h]$ of the quantized universal enveloping algebra [Dr1]. This algebra is called the dual quantized universal enveloping algebra $A^\vee$. Drinfeld [Dr1] showed that there exists a unique structure of a topological Hopf algebra on $(\sum_{n\geq 0} h^{-n}(I^\ast)^n)$. Let $\Delta$ be the maximal ideal in $\sum_{n\geq 0} h^{-n}(I^\ast)^n$. Then $A^\vee$ is a new quantized universal enveloping algebra $[\text{Dr1}]$. This algebra is called the dual quantized universal enveloping algebra to $A$.

The algebra $A^\ast$ can be identified with a subalgebra in $A^\vee$ which is constructed as follows.

Let $\Delta^n : A \to A^\otimes n$ be the iterated coproduct maps: $\Delta^0(a) = \varepsilon(a)$, $\Delta^1(a) = a$, $\Delta^2(a) = \Delta(a)$, $\Delta^n(a) = (\Delta \otimes 1^\otimes (n-2))((\Delta^{n-1}(a))$, $n > 2$.

Let $\Sigma = \{i_1, ..., i_k\} \subset \{1, ..., n\}$, and $i_1 < ... < i_k$. Let $j_\Sigma : A^\otimes k \to A^\otimes n$ be the homomorphism defined by $j_\Sigma(a_1 \otimes ... \otimes a_k) = b_1 \otimes ... \otimes b_n$, $a_1, ..., a_k \in A$, where $b_i = 1$ if $i \notin \Sigma$, and $b_{i_m} = a_m$, $m = 1, ..., k$.

Let $\Delta_\Sigma(a) = j_\Sigma(\Delta^k(a))$, $a \in A$.

Define linear mappings $\delta_n : A \to A^\otimes n$ for all $n \geq 1$ by

$$\delta_n(a) = \sum_{\Sigma \subset \{1, ..., n\}} (-1)^{n-|\Sigma|} \Delta_\Sigma(a)$$

and a Hopf subalgebra $A' = \{a \in A : \delta_n(a) \in h^n A^\otimes n\}$ in $A$.

It is easy to check that $A^\ast = (A^\vee)'$.

If $A$ is any Hopf algebra, let $A^{\text{op}}$ denote the Hopf algebra $A$ with the comultiplication $\Delta$ replaced by $\Delta^{\text{op}}$, and the antipode $S$ replaced with $S^{-1}$. $A^{\text{op}}$ is also a Hopf algebra.

Now we can define the notion of the quantum double. Let $A$ be a quantized universal enveloping algebra. Consider the $k[[h]]$-module $D(A) = A \otimes (A^\ast)^{\text{op}}$. Let $R \in A \otimes A^\ast \subset A \otimes (A^\vee)^{\text{op}}$ be the canonical element. We can regard $R$ as an element of $D(A) \otimes D(A)$ using the embedding $A \otimes (A^\ast)^{\text{op}} \to D(A) \otimes D(A)$ given by $x \otimes y \to x \otimes 1 \otimes 1 \otimes y$. Drinfeld [Dr1] showed that there exists a unique structure of a topological Hopf algebra on $D(A)$ such that

1) $A \otimes 1, 1 \otimes (A^\vee)^{\text{op}}$ are Hopf subalgebras in $D(A)$,

2) $R$ defines a quasitriangular structure on $D(A)$, i.e. is invertible and satisfies (3.12), (3.13), and

3) The linear mapping $A \otimes (A^\vee)^{\text{op}} \to D(A)$ given by $a \otimes b \to ab$ is bijective.

$D(A)$, equipped with this structure, is a quasitriangular quantized universal enveloping algebra. It is called the quantum double of $A$.

4.5. The quantum double of $U_h(\mathfrak{g}^+)$.  

\textbf{Proposition 4.8.} $\rho$ is a homomorphism of topological Hopf algebras $(U_h(\mathfrak{g}^-)^{\text{op}})^* \to U_h(\mathfrak{g}^+)$. $\rho$ is a homomorphism of topological Hopf algebras $U_h(\mathfrak{g})^* \to U_h(\mathfrak{g}^+)$. 

\textbf{Proof.} We only prove the first statement. The second one is proved analogously.

It is clear that $\rho$ is continuous. Also, for any $f, g \in (U_h(\mathfrak{g}^-)^{\text{op}})^*$ one has

$$\rho(fg) = (1 \otimes f g)(R) = (1 \otimes f \otimes g)((1 \otimes \Delta^{\text{op}})(R)) = (1 \otimes f \otimes g)(R_{12}R_{13}) =
(1 \otimes f)(R) \cdot (1 \otimes g)(R) = \rho(f)\rho(g);$$

$$\Delta(\rho(f)) = \Delta((1 \otimes f)(R)) = (1 \otimes 1 \otimes f)((\Delta \otimes 1)(R)) =$$

$$(1 \otimes 1 \otimes f)(R_{13}R_{23}) = (1 \otimes 1 \otimes \Delta(f))(R_{13}R_{24}) = (\rho \otimes \rho)(\Delta(f)).$$
It is obvious that $\rho_+(1) = 1$ and $\varepsilon(\rho_+(f)) = \varepsilon(f)$ for any $f$. Also, it is easy to check that $\rho_+(S^{-1}f) = S(\rho_+(f))$. The proposition is proved. \qed

**Corollary 4.9.** $U_{\pm}$ are Hopf subalgebras in $U_h(g_{\pm})$. In particular, $\tilde{U}_{\pm} = U_{\pm}$.

**Proof.** The first statement is clear. The second statement follows from the first one and the fact that $U_{\pm}$ is closed in $U_h(g_{\pm})$, which is easy to check. \qed

**Proposition 4.10.** The maps $\rho_+$, $\rho_-$ are injective.

**Proof.** We show the injectivity of $\rho_+$ (the case of $\rho_-$ is similar). Fix an element $f \in \tilde{U}_h(g_-)^* \setminus \{0\}$. We can always assume that $f \not\equiv 0 \mod h$. Let $x \in U(g_-)$ be such that $f(tx) \not\equiv 0 \mod h$ (where $tx$ was defined in Lemma 4.6), $n \geq 0$ be such that $h^ntx \in U_-$, and $g \in U_h(g_+)^*$ be such that $\rho_-(g) = h^ntx$. Such a $g$ exists by the definition of $n$. Then $g(\rho_+(f)) = (g \otimes f)(R) = f(\rho_-(g)) = h^n f(tx) \neq 0$. Therefore, $\rho_+(f) \neq 0$. \qed

**Proposition 4.11.** $U_{\pm} = U_h(g_{\pm})'$.

**Proof.** We give the proof for $U_+$. The proof for $U_-$ is similar.

First we need the following statement.

**Lemma 4.12** Let $t \in U_h(g_+)'$ be an element such that $h^{-n}t \in U_h(g_+)$ and $h^{-n}t = x + O(h)$, $x \in U(g_+)$, $x \neq 0$. Then $x$ has degree $\leq n$.

**Proof of the Lemma.** By the definition, $\delta_{n+1}(h^{-n}t)$ is divisible by $h$. On the other hand, $\delta_{n+1}(h^{-n}t) = \delta_{n+1}(x) + O(h)$. Thus, $\delta_{n+1}(x) = 0$, which implies that the degree of $x$ is $\leq n$, since the kernel of $\delta_{n+1}$ on $U(g_+)$ is the set of all elements of $U(g_+)$ whose degree is $\leq n$. \qed

Now we can prove the proposition. By Lemma 4.6, for any $x \in U(g_+)$ of degree $\leq n$, an element $tx$ can be chosen in such a way that $h^n tx \in U_+$. This implies the inclusion $U_+ \supset U_h(g_+)'$. Indeed, let $T_0 \in U_h(g_+)'$, and $T_0 \equiv h^mx_0 \mod h^{m+1}$, where $x_0 \in U(g_+)$. Then, according to Lemma 4.12, the degree of $x_0$ is $\leq m$. Therefore, $h^m tx_0 \in U_+$. Thus, $T_1 = T_0 - h^m tx_0 \in U_+$ and is divisible by $h^{m+1}$, so we can repeat our procedure. This gives us a sequence of elements $x_i \in U(g_+)$ of degrees $m_i$ ($m_0 = m$), such that $m_0 < m_1 < \ldots < m_i < \ldots$, and $T_0 = \sum_{i \geq 0} tx_i h^{m_i}$. This shows that $T_0$ belongs to $U_+$, as desired.

To demonstrate the inclusion $U_+ \subset U_h(g_+)'$, observe that according to (3.12),

$$(\Delta^n \otimes 1)(R) = R_{1n+1} \ldots R_{nn+1}.$$ 

This implies that

$$(\delta_n \otimes 1)(R) = (R_{1n+1} - 1) \ldots (R_{nn+1} - 1) = O(h^n).$$

Therefore, $\delta_n(\rho_+(f))$ is divisible by $h^n$ for any $f \in U_h(g_-)^*$. \qed

Comparing our results with the definitions of the previous, section we see that we have obtained the following result.

**Theorem 4.13.** Let $g_+$ be a finite dimensional Lie bialgebra and $(g, g_+, g_-)$ be the associated Manin triple. Then

(i) There exist quantized universal enveloping algebras $U_h(g)$ and $U_h(g_{\pm}) \subset U_h(g)$, which are quantizations of the Lie bialgebras $g$, $g_{\pm} \subset g$, respectively;

(ii) The multiplication map $U_h(g_+) \otimes U_h(g_-) \rightarrow U_h(g)$ is a linear isomorphism;
(iii) The algebras $U_h(\mathfrak{g}^+), U_h(\mathfrak{g}^-)^{op}$ are dual to each other as quantized universal enveloping algebras, in the sense of Drinfeld [Dr1];

(iv) The factorization $U_h(\mathfrak{g}) = U_h(\mathfrak{g}^+) U_h(\mathfrak{g}^-)$ defines an isomorphism of $U_h(\mathfrak{g})$ with the quantum double of $U_h(\mathfrak{g}^+)$;

(v) $U_h(\mathfrak{g})$ is isomorphic to $U(\mathfrak{g})[[h]]$ as a topological algebra.

5. Quantization of solutions of the classical Yang-Baxter equation.

Let $A$ be an associative algebra over $k$ with unit, and $r \in A \otimes A$. The element $r$ is called a classical $r$-matrix if it satisfies the classical Yang-Baxter equation

$$[r_{12}, r_{13}] + [r_{12}, r_{23}] + [r_{13}, r_{23}] = 0. \tag{5.1}$$

We say that $r$ is unitary if $r^{op} = -r$. An algebra $A$ equipped with a classical $r$-matrix $r$ is called a classical Yang-Baxter algebra. $A$ is called unitary if $r$ is unitary.

Let $A$ be a topological algebra over $k[[h]]$. Let $R \in A \otimes A$. We say that $R$ is a quantum $R$-matrix if it satisfies the quantum Yang-Baxter equation

$$R_{12} R_{13} R_{23} = R_{23} R_{13} R_{12} \tag{5.2}$$

We say that $R$ is unitary if $R^{op} = R^{-1}$. A topological algebra $A$ equipped with a quantum $R$-matrix $R$ is called a quantum Yang-Baxter algebra. $A$ is called unitary if $R$ is unitary.

The following theorem answers question 3.1 in [Dr3]. It shows that any classical Yang-Baxter algebra can be quantized.

**Theorem 5.1.** Let $A$ be an associative algebra with unit over $k$, and $r \in A \otimes A$ be a classical $r$-matrix. Then there exists a quantum $R$-matrix $R \in A \otimes A[[h]]$ such that $R = 1 + hr \mod h^2$. If in addition $r$ is unitary then $R$ can also be chosen unitary.

**Proof.**

We start with a construction of Reshetikhin and Semenov-Tian-Shansky [RS]. Let $\mathfrak{g}^+_+ = \{(1 \otimes f)(r), f \in A^*\}, \mathfrak{g}^- = \{(f \otimes 1)(r), f \in A^*\}$ be vector subspaces in $A$. It is clear that $\mathfrak{g}^+\mathfrak{g}^-$ are finite-dimensional, $r \in \mathfrak{g}^+ \otimes \mathfrak{g}^-$, and the map $\chi_r : \mathfrak{g}^+_+ \rightarrow \mathfrak{g}^-$ defined by $\chi_r(f) = (f \otimes 1)(r)$, is an isomorphism of vector spaces.

**Remark.** Note that the spaces $\mathfrak{g}^+$ and $\mathfrak{g}^-$ may intersect nontrivially and even coincide.

**Lemma 5.2.** $\mathfrak{g}^+, \mathfrak{g}^-$ are Lie subalgebras in $A$.

**Proof.** Let $x, y \in \mathfrak{g}^+$, $x = (1 \otimes f)(r), y = (1 \otimes g)(r)$. Using (5.1), we have

$$[xy] = (1 \otimes f \otimes g)([r_{12}, r_{13}]) = (1 \otimes f \otimes g)([r_{12}, r_{13}, r_{23}]) = (1 \otimes h)(r),$$

where $h \in A^*, h(a) = (f \otimes g)([r, a \otimes 1 + 1 \otimes a])$. Thus, $[xy] \in \mathfrak{g}^+$, i.e. $\mathfrak{g}^+$ is a Lie algebra. The proof for $\mathfrak{g}^-$ is similar. □

Let $\mathfrak{g} = \mathfrak{g}^+ \oplus \mathfrak{g}^-$ be a vector space. Define the skew-symmetric bracket $[,] : \mathfrak{g} \otimes \mathfrak{g} \rightarrow \mathfrak{g}$ as follows. If $x, y \in \mathfrak{g}^+$ or $x, y \in \mathfrak{g}^-$ then the bracket $[xy]$ is the Lie bracket in $\mathfrak{g}^+$ or $\mathfrak{g}^-$, respectively. If $x \in \mathfrak{g}^+, y \in \mathfrak{g}^-$, then $[xy]$ is defined by

$$[xy] = (ad^* x)y - (ad^* y)x. \tag{5.4}$$

Let $\pi : \mathfrak{g} \rightarrow A$ be the linear map whose restrictions to $\mathfrak{g}^+, \mathfrak{g}^-$ are the corresponding embeddings. The restrictions of $\pi$ to $\mathfrak{g}^+, \mathfrak{g}^-$ are injective but in general $\pi$ itself is not an embedding.
Lemma 5.3. \( \pi([xy]) = [\pi(x), \pi(y)], \ x, y \in \mathfrak{g}. \)

Proof. The Lemma is a direct consequence of the classical Yang-Baxter equation. \( \square \)

Lemma 5.4. \((\mathfrak{g}, [,])\) is a Lie algebra.

Proof. We have to check the Jacobi identity in \( \mathfrak{g}. \) It is enough to check it for three elements \( a, x, y \) such that \( a \in \mathfrak{g}_+, \ x, y \in \mathfrak{g}_-. \) For brevity we write \( a(x) \) for \( (\text{ad}^* a)x. \) We have

\[
\begin{align*}
[a[xy]] &= a([xy]) - [xy](a), \\
[y[ax]] &= [y, a(x) - x(a)] = [y, a(x)] - y(x(a)) + y(a(x)), \\
[x[ya]] &= [x, y(a) - a(y)] = -[x, a(y)] + x(y(a)) - x(a(y)).
\end{align*}
\]

Adding these three identities, and using the fact that \([xy](a) = x(y(a)) - y(x(a)),\)

we get

\[
(5.6) \quad [a[xy]] + [y[ax]] + [x[ya]] = a([xy]) + [y, a(x)] - [x, a(y)] + y(a(x)) - x(a(y)).
\]

Denote the right hand side of (5.6) by \( X. \) Applying \( \pi \) to both sides of (5.6), and using Lemma 5.3 and the Jacobi identity in \( A, \) we get

\[
(5.7) \quad \pi(X) = 0.
\]

Since \( X \in \mathfrak{g}_+, \) and \( \pi \) is injective on \( \mathfrak{g}_+, \) we get \( X = 0, \) which implies the Jacobi identity in \( \mathfrak{g}. \) \( \square \)

Let \( \langle \cdot, \cdot \rangle \) be the inner product on \( \mathfrak{g} \) such that \( \langle x_+ + x_- , y_+ + y_- \rangle = x_- \cdot y_+ + y_- \cdot x_+, \)

where \( x_+, y_+ \in \mathfrak{g}_+, \)

\( x_-, y_- \in \mathfrak{g}_-, \) and the dot denotes the natural pairing \( \mathfrak{g}_- \otimes \mathfrak{g}_+ \to k \)

defined by the map \( \chi_r. \) This inner product is ad-invariant. Thus, \((\mathfrak{g}, \mathfrak{g}_+, \mathfrak{g}_-)\) is a Manin triple.

Now we can finish the proof of the theorem. Lemma 5.3 implies that \( \pi : \mathfrak{g} \to A \)

is a homomorphism of Lie algebras. Therefore, it extends to a homomorphism of associative algebras \( \pi : U(\mathfrak{g}) \to A. \) Furthermore, \((\mathfrak{g}, \mathfrak{g}_+, \mathfrak{g}_-)\) is a Manin triple. The Lie bialgebra \( \mathfrak{g} \) is quasitriangular, and its quasitriangular structure is defined by the classical r-matrix \( \tilde{r} = \sum x_+^i \otimes x_-^i, \)

where \( x_+^i \) is a basis of \( \mathfrak{g}_+, \) and \( x_-^i \) is a dual basis of \( \mathfrak{g}_-. \) Note that \( (\pi \otimes \pi)(\tilde{r}) = r. \)

By Theorem 4.13, there exists a quasitriangular topological Hopf algebra \( U_h(\mathfrak{g}), \)

with a quasitriangular structure \( \tilde{R} \in U_h(\mathfrak{g}) \otimes U_h(\mathfrak{g}). \) Moreover, the associative algebra \( U_h(\mathfrak{g}) \) is isomorphic to \( U(\mathfrak{g})[[h]], \) and the isomorphism can be chosen to be the identity modulo \( h. \) Thus, we can assume that \( \tilde{R} \in (U(\mathfrak{g}) \otimes U(\mathfrak{g}))[h]. \)

Set \( R = (\pi \otimes \pi)(\tilde{R}). \) From what we said above it follows that \( R \) satisfies (5.2) and \( R = 1 + hr \) modulo \( h^2. \)

Assume now that \( r^\text{op} = -r. \) Let \( \tilde{\Omega} = \tilde{r} + r^\text{op}. \) It follows immediately from the construction of \( \tilde{R} \) that \( R^\text{op} \tilde{R} \) is conjugate to \( e^{h\tilde{\Omega}}. \) But \( (\pi \otimes \pi)(\tilde{\Omega}) = r + r^\text{op} = 0. \) This implies that \( R^\text{op} R = 1, \) as desired.

The theorem is proved. \( \square \)

Let \( \mathcal{R} \) be the ring of algebraic functions of a variable \( h \) with coefficients in \( k \)

which are regular at \( h = 0. \)
**Theorem 5.5.** Let $A$ be a finite-dimensional associative algebra with unit over $k$, and $r \in A \otimes A$ be a classical $r$-matrix. Then there exists a family of quantum $R$-matrices $R(h) \in A \otimes A \otimes R$ such that $R = 1 + hr + O(h^2)$, $h \to 0$. If in addition $r$ is unitary then $R(h)$ can also be chosen unitary.

**Proof.** The theorem follows immediately from Theorem 5.1 and the following result of M. Artin [Ar].

**Theorem.** Any system of polynomial equations in indeterminates $x_1, \ldots, x_n$ with coefficients in $k[[h]]$ which has solutions over $k[[h]]$ also has solutions over $\mathcal{R}$. Indeed, let us write $R$ in the form $R = 1 + hr + h^2 X(h)$, and look for a series $X(h)$ such that $R$ satisfies the quantum Yang-Baxter equation, and the unitarity condition in the case when $r$ is unitary. This is a system of polynomial equations on the components of $X(h)$ with coefficients in $k[[h]]$. By Theorem 5.1, it has solutions over $k[[h]]$. Therefore, by Artin’s theorem, it has solutions over $\mathcal{R}$.

### 6. Quantization of quasitriangular Lie bialgebras.

#### 6.1. Quasitriangular quantization of quasitriangular Lie bialgebras.

In this section we give a recipe of quantization of a quasitriangular Lie bialgebra $\mathfrak{a}$ (not necessarily finite dimensional), which produces a quantized universal enveloping algebra isomorphic to $U(\mathfrak{a})[[h]]$ as a topological algebra. This answers questions from Section 4 of [Dr3].

Let $\mathfrak{g}_+ = \{(1 \otimes f)(r), f \in \mathfrak{a}^*\}$, $\mathfrak{g}_- = \{(f \otimes 1)(r), f \in \mathfrak{a}^*\}$. be subspaces in $\mathfrak{a}$. By Lemma 5.2, applied to $A = U(\mathfrak{a})$, these subspaces are finite dimensional Lie subalgebras in $\mathfrak{a}$. Moreover, let $\mathfrak{g}$ be the vector space $\mathfrak{g}_+ \oplus \mathfrak{g}_-$. This space is a Lie algebra with bracket defined by (5.4) and an invariant inner product. By Lemma 5.3, we have a natural homomorphism of Lie algebras $\pi : \mathfrak{g} \to \mathfrak{a}$, and it is easy to see that this homomorphism is a morphism of quasitriangular Lie bialgebras.

Let $\mathcal{M}_\mathfrak{a}$ be the category whose objects are $\mathfrak{a}$-modules, and morphisms are defined by $\text{Hom}_{\mathcal{M}_\mathfrak{a}}(V, W) = \text{Hom}_\mathfrak{a}(V, W)[[h]]$. Let $\mathcal{M}_\mathfrak{g}$ be the Drinfeld category associated to $\mathfrak{g}$. We have the pullback functor $\pi^* : \mathcal{M}_\mathfrak{a} \to \mathcal{M}_\mathfrak{g}$. Define the braided monoidal structure on $\mathcal{M}_\mathfrak{a}$ to be the pullback of the braided monoidal structure on $\mathcal{M}_\mathfrak{g}$. This definition makes sense, since the element $\Omega = r + r^{op} \in \mathfrak{g} \otimes \mathfrak{g}$ is $\mathfrak{g}$-invariant by the definition of a quasitriangular Lie bialgebra.

Let $M_+, M_-$ be the Verma modules over $\mathfrak{g}$. Define a functor $F : \mathcal{M}_\mathfrak{a} \to \mathfrak{A}$ by $F(V) = \text{Hom}_{\mathcal{M}_\mathfrak{g}}(M_+ \otimes M_-, \pi^*(V))$. The tensor structure on $F$ is introduced in the same way as in Section 1.8. Let $G = \text{End}F$. Since the functor $F$ is isomorphic to the “forgetful” functor $V \to \text{ “ the } k[[h]] \text{ module } V[[h]] \text{ ” }$, the algebra $H$ is isomorphic to $U(\mathfrak{a})[[h]]$ as a topological algebra over $k[[h]]$. On the other hand, $H$ has a natural coproduct and antipode defined analogously to Section 3.2, and a quasitriangular structure $R \in H \otimes H$ defined analogously to Section 3.5. It is easy to check that the quasiclassical limit of $H$ is the Lie bialgebra $\mathfrak{a}$, and $R = 1 + hr + O(h^2)$, so $r$ is the quasiclassical limit of $R$.

Furthermore, suppose that the original Lie bialgebra $r$ is triangular, i.e. $r$ is a unitary $r$-matrix. Then $\Omega = r + r^{op} = 0$, and hence $R^{op} R = J^{-1} e^{h\Omega} J = 1$, so the Hopf algebra $H$ is triangular, too.

Thus, we have the following theorem.

**Theorem 6.1.** Any quasitriangular Lie bialgebra $\mathfrak{a}$ admits a quantization $U_h(\mathfrak{a})$ which is a quasitriangular quantized universal enveloping algebra isomorphic to
$U(a)[[\hbar]]$ as a topological algebra. If $a$ is triangular, so is $U_h(a)$.

6.2. Identification of two quantizations of a quasitriangular Lie bialgebra. Let $a$ be a finite dimensional quasitriangular Lie bialgebra. Let $U_h(a)$ be the quantization of $a$ constructed in Section 4, and $U^{qt}_h(a)$ be the quasitriangular quantization of $a$ constructed in Section 6.1.

**Theorem 6.2.** The quantized universal enveloping algebras $U_h(a)$, $U^{qt}_h(a)$ are isomorphic.

The proof of this theorem is given below and uses the functoriality of quantization, which is proved in Chapter 10.

**Corollary 6.3.** The quantization of the double $g$ of a finite dimensional Lie bialgebra $a$ constructed in Chapter 3 is isomorphic to the quantization of $g$ as a Lie bialgebra, constructed in Chapter 4.

To prove Theorem 6.2, we first need the following result, which appears (in somewhat different form) in [RS].

**Lemma 6.4.** Let $a$ be a quasitriangular Lie bialgebra, and $g$ be the double of $a$. Then the linear map $\tau: g \to a$ defined by

$$\tau(x + f) = x + (f \otimes 1)(r), x \in a, f \in a^*,$$

is a homomorphism of quasitriangular Lie bialgebras.

**Proof.** First we show that $\tau$ is a homomorphism of Lie algebras, i.e. $\tau([g_1g_2]) = [\tau(g_1)\tau(g_2)]$. This is obvious when $g_1, g_2 \in a$. Assume that $f, g \in a^*$. Then, using the classical Yang-Baxter equation, we get

$$\tau([fg]) = ([fg] \otimes 1)(r) = (f \otimes g \otimes 1)((\delta \otimes 1)(r)) = (f \otimes g \otimes 1)([r_{13}, r_{23}]) = [\tau(f)\tau(g)].$$

Now assume that $x \in a, f \in a^*$. Then

$$\tau([xf]) = \tau(ad^*x(f)) - \tau(ad^*f(x)) = \tau((f \otimes 1)([r, x \otimes 1])) + \tau((f \otimes 1)([x \otimes 1 + 1 \otimes x, r])) = \tau((f \otimes 1)([1 \otimes x, r])) = [\tau(x)\tau(f)].$$

Now we check that $\tau$ is a homomorphism of quasitriangular Lie bialgebras. Let $\tilde{\tau}$ be the quasitriangular structure on $g$. If $x_i$ is a basis of $a$, and $f_i$ is the dual basis of $a^*$, then $\tilde{\tau}$ is given by the formula $\tilde{\tau} = \sum_i x_i \otimes f_i$. Thus we have

$$(\tau \otimes \tau)(\tilde{\tau}) = \sum_i \tau(x_i) \otimes \tau(f_i) = \sum_i x_i \otimes (f_i \otimes 1)(r) = r.$$

The Lemma is proved. □

**Proof of Theorem 6.2.** Lemma 6.4 claims that there exists a morphism of quasitriangular Lie bialgebras $\tau: g \to a$ which is the identity on $a$. Theorem 10.6 below
states that quasitriangular quantization of Section 6.1 is a functor from the category of quasitriangular Lie bialgebras to the category of quasitriangular topological Hopf algebras over $k[[h]]$. Thus, $\tau$ defines a morphism $\tilde{\tau} : U^q_t(g) \to U^q_t(a)$. On the other hand, $U_h(a)$ was constructed as a subalgebra in $U^q_t(g)$, so we have an embedding $\eta : U_h(a) \to U^q_t(g)$. Consider the morphism $\tau \circ \eta : U_h(a) \to U^q_t(a)$. This morphism is an isomorphism since it equals to 1 modulo $h$. The theorem is proved. □

Remark. An analogous theorem holds for infinite dimensional Lie bialgebras. Namely, the “usual” quantization of $a$ defined in Section 9 is isomorphic to its quasitriangular quantization. The proof is analogous to the finite dimensional case.

6.3. Representations of $U_h(g)$.

Let $a$ be a quasitriangular Lie bialgebra (not necessarily finite dimensional). By a representation of $U_h(a)$ we mean a topologically free $k[[h]]$-module $V$ together with a homomorphism $\pi : U_h(a) \to \text{End}_{k[[h]]}V$. Representations of $U_h(g)$ form a braided tensor category, with the trivial associativity morphism and braiding defined by the $R$-matrix. Denote this category by $\mathcal{R}$.

The functor $F : \mathcal{M}_a \to \mathcal{A}$ can be regarded as a functor from $\mathcal{M}_a$ to $\mathcal{R}$, since for any $W \in \mathcal{M}_a$ the $k[[h]]$-module $F(W)$ is equipped with a natural action of $U_h(g)$. We denote this new functor also by $F$. This functor inherits the tensor structure defined by the maps $J_{VW}$.

Theorem 6.5. The functor $F$ defines an equivalence of braided tensor categories $\mathcal{M}_a \to \mathcal{R}$.

Proof. The theorem follows from the definition of the functor $F$, the algebra $U_h(g)$ and the R-matrix $R$. □

Part II

7. Drinfeld category for an arbitrary Lie bialgebra.

7.1. Topological vector spaces. Recall the definition of the product topology. Let $S$ be a set, $T$ a topological space, and $T^S$ the space of functions from $S$ to $T$. This space has a natural weak topology, which is the weakest of the topologies in which all the evaluation maps $T^S \to T, f \mapsto f(s)$, are continuous. Namely, let $B$ be a basis of the topology on $T$. For any integer $n \geq 1$, elements $s_1, \ldots, s_n \in S$, and open sets $U_1, \ldots, U_n \in B$, define $V(s_1, \ldots, s_n, U_1, \ldots, U_n) = \{f \in T^S : f(s_i) \in U_i, i = 1, \ldots, n\}$. Let $B$ be the collection of all such sets $V$. This is a basis of a topology on $T^S$ which is called the weak topology. The obtained topological space is the product of copies of $T$ corresponding to elements of $S$. If $X$ is any subset in $T^S$, the weak topology on $T^S$ induces a topology on $X$. We will call it the weak topology as well.

Let $k$ be a field of characteristic zero with the discrete topology. Let $V$ be a topological vector space over $k$. The topology on $V$ is called linear if open subspaces of $V$ form a basis of neighborhoods of 0.

Remark. It is clear that in any topological vector space, an open subspace is also closed.

Let $V$ be a topological vector space over $k$ with linear topology. $V$ is called separated if the map $V \to \varprojlim(V/U)$ is a monomorphism, where $U$ runs over open subspaces of $V$. 

22
Topology on all vector spaces we consider in this paper will be linear and separated. So we will say “topological vector space” for “separated topological vector space with linear topology”.

Let $M, N$ be topological vector spaces over $k$. We denote by $\text{Hom}_k(M, N)$ the space of continuous linear operators from $M$ to $N$, equipped with the weak topology. It is clear that a basis of neighborhoods of zero in $\text{Hom}_k(M, N)$ is generated by sets of the form $\{A \in \text{Hom}_k(M, N) : Av \in U\}$, where $v \in M$, and $U \subset N$ is an open set.

In particular, if $N = k$ with the discrete topology, the space $\text{Hom}_k(M, N)$ is the space of all continuous linear functionals on $M$, which we denote by $M^*$. It is clear that a basis of neighborhoods of zero in $M^*$ consists of orthogonal complements of finite-dimensional subspaces in $M$. In particular, if $M$ is discrete then the canonical embedding $M \rightarrow (M^*)^*$ is an isomorphism of linear spaces. However, if $M$ is infinite-dimensional, this embedding is not an isomorphism of topological vector spaces since the space $(M^*)^*$ is not discrete.

7.2 Complete vector spaces
Let $V$ be a topological vector space over $k$. $V$ is called complete if the map $V \rightarrow \lim V/U$ is an epimorphism, where $U$ runs over open subspaces of $V$.

In particular, if a complete space $M$ has a countable basis of neighborhoods of 0, then there exists a filtration $M = M_0 \supset M_1 \supset \ldots$, such that $\cap_{n \geq 0} M_n = 0$, and $\{M_n\}$ is a basis of neighborhoods of zero in $M$. In this case $M = \lim_{n \rightarrow \infty} M/M_n$.

Examples. 1. Any discrete vector space is complete.

2. If $V$ is a discrete vector space then the topological space $M = V[[h]]$ of formal power series in $h$ with coefficients in $V$ is a complete vector space.

Let $V$ be a complete vector space, $U \subset V$ an open subspace. Then $U$ is complete and $V/U$ is discrete.

Let $V, W$ be complete vector spaces. Consider the space $V \hat{\otimes} W = \lim V/V_1 \otimes W/W_1$, where the projective limit is taken over open subspaces $V_1 \subset V$, $W_1 \subset W$. It is easy to see that $V \hat{\otimes} W$ is a complete vector space. We call the operation $\hat{\otimes}$ the completed tensor product.

A basis of neighborhoods of 0 in $V \hat{\otimes} W$ is the collection of subspaces $V \hat{\otimes} W_1 + V_1 \otimes W$, where $V_1, W_1$ are open subspaces in $V, W$.

Example. Let $V$ be a discrete space. Then $V \hat{\otimes} k[[h]] = V[[h]]$.

Complete vector spaces form an additive category in which morphisms are continuous linear operators. This category, equipped with tensor product $\hat{\otimes}$, is a strict symmetric tensor category.

7.3. Equicontinuous $g$-modules.
Let $M$ be a topological vector space over $k$, and $\{A_x, x \in X\}$ be a family of elements of $\text{End} M$. We say that the family $\{A_x\}$ is equicontinuous if for every neighborhood of the origin $U \subset M$ there exists another neighborhood of the origin $U' \subset M$ such that $A_x U' = U$ for all $x \in X$. For example, if $M$ is complete and $A \in \text{End} M$ is any continuous linear operator, then $\{\lambda A, \lambda \in k\}$ is equicontinuous.

Fix a topological Lie algebra $g$.

Definition. Let $M$ be a complete vector space. We say that $M$ is an equicontinuous $g$-module if one is given a continuous homomorphism of topological Lie algebras $\pi : g \rightarrow \text{End} M$, such that the family of operators $\pi(g), g \in g$, is equicontinuous.
Example. If $M$ is a complete vector space with a trivial $g$-module structure then $M$ is an equicontinuous $g$-module.

Let $V, W$ be equicontinuous $g$-modules. It is easy to check that $V \otimes W$ has a natural structure of an equicontinuous $g$-module. Moreover, $(V \otimes W) \otimes U$ is naturally identified with $V \otimes (W \otimes U)$ for any equicontinuous $g$-modules $V, W, U$. This means that the category of equicontinuous $g$-modules, where morphisms are continuous homomorphisms, is a monoidal category. This category is symmetric since the objects $V \otimes W$ and $W \otimes V$ are identified by the permutation of components. We denote this category by $\mathcal{M}_g$.

7.4. Lie bialgebras and Manin triples. Let $a$ be a Lie bialgebra over $k$. We will regard $a$ as a topological Lie algebra with the discrete topology. Let $a^*$ be the full dual space to $a$. The cocommutator defines a Lie bracket on $a^*$ which is continuous in the weak topology, so $a^*$ has a natural structure of a topological Lie algebra.

Furthermore, the space $a \oplus a^*$ has a natural topology, and the Lie bracket on $g$ defined by (1.1) is continuous in this topology.

Let $g$ be a Lie algebra with a nondegenerate invariant inner product $\langle , \rangle$. So far we have no topology on $g$. Let $g_+, g_-$ be isotropic Lie subalgebras in $g$, such that $g = g_+ \oplus g_-$ as a vector space. The inner product $\langle , \rangle$ defines an embedding $g_- \to g_+^*$. If this embedding is an isomorphism then we equip $g$ with a topology, by putting the discrete topology on $g_+$ and the weak topology on $g_-$. If in addition the commutator in $g$ is continuous in this topology then the triple $(g, g_+, g_-)$ is called a Manin triple.

To every Lie bialgebra $a$ one can associate the corresponding Manin triple $(g = a \oplus a^*, a, a^*)$, where the Lie structure on $g$ is as above. Conversely, if $(g, g_+, g_-)$ is a Manin triple then $g_+$ is naturally a Lie bialgebra: the pairing $\langle , \rangle$ identifies $g_+^*$ with $g_-$, which defines a commutator on $g_+^*$. This commutator turns out to be dual to a 1-cocycle (cf. [Dr1]).

Thus, there is a one-to-one correspondence between Lie bialgebras and Manin triples.

Let $(g, g_+, g_-)$ be a Manin triple. Let $\{a_i, i \in I\}$ be a basis of $g_+$, and $b^i \in g_-$ be the linear functions on $a$ defined by $b^i(a_j) = \delta_{ij}$.

**Lemma 7.1.** Let $M$ be an equicontinuous $g$-module. Then for any $v \in M$ and any neighborhood of zero $U \subset M$ one has $b^iv \in U$ for all but finitely many $i \in I$.

**Proof.** We assume that $	ext{dim} g_+ = \infty$ (otherwise there is nothing to prove).

Let $\{i_m \in I : m \geq 1\}$ be any sequence of distinct elements. The $b^{i_m} \to 0$, $m \to \infty$, so $b^{i_m}v \to 0$, $m \to \infty$, for any $v \in M$. This means that $b^iv \in U$ for almost all $i$. \hfill $\Box$

7.5. Examples of equicontinuous $g$-modules.

In this section we will construct examples of equicontinuous $g$-modules in the case when $g$ belongs to a Manin triple $(g, g_+, g_-)$.

Consider the Verma modules $M_+ = \text{Ind}_{\mathfrak{g}_+}^g \mathbf{1}$, $M_- = \text{Ind}_{\mathfrak{g}_-}^g \mathbf{1}$, (here $\mathbf{1}$ denotes the trivial 1-dimensional representation). The modules $M_\pm$ are freely generated over $U(\mathfrak{g}_\pm)$ by a vector $1_\pm$ such that $\mathfrak{g}_\pm 1_\pm = 0$, and thus are identified (as vector spaces) with $U(\mathfrak{g}_\pm)$ via $x 1_\pm \to x$.

Below we show that the module $M_-$ and the module $M_+^*$ dual to $M_+$ in an appropriate sense are equicontinuous $g$-modules.
Lemma 7.2. The module $M_-$, equipped with the discrete topology, is an equicon-

continous $\mathfrak{g}$-module.

Proof. In order to prove the continuity of $\pi_{M_-}(g)$ as a function on $\mathfrak{g}$, we have
to check that for any $v \in M_-$ the space $\mathfrak{g}_- v \subset M_-$ is finite dimensional. One
may assume that $v = a_1 a_2 ... a_n 1_-$. We show that $\mathfrak{g}_- v$ is finite dimensional by
induction in $n$. The base of induction is clear since $\mathfrak{g}_- v = 0$ if $n = 0$. Now assume
that $v = a_j w$, where $w = a_1 a_2 ... a_{n-1} 1_-$. By the induction assumption, we know that
$\mathfrak{g}_- w$ is finite dimensional. For any $b \in \mathfrak{g}_-$ we have $bw = ba_j w = [ba_j]w + a_j bw$. For
any $j \in I$ we denote by $W_j \subset \mathfrak{g}_-$ space of all $b \in \mathfrak{g}_-$ such that $(1 \otimes b)(\delta(a_j)) = 0$. It
is clear that $W_j$ has finite codimension. For any $b \in W_j$, we have $[ba_j] \in \mathfrak{g}_-$, since
$\text{ad}^* b(a_j) = 0$ by the definition of $W_j$. Therefore, for any $b \in W_j$ $bw = [ba_j]w + a_j bw \in 
\mathfrak{g}_- w + a_j \mathfrak{g}_- w$. The latter space is finite dimensional, which implies that $W_j v$ is
finite dimensional. Since $W_j$ has a finite codimension in $\mathfrak{g}_-$, the space $\mathfrak{g}_- v$ is finite-
dimensional. This implies the continuity of the homomorphism $\pi_{M_-} : \mathfrak{g} \to \text{End}M_-$. The
equicontinuity condition is trivial. □

Let us now introduce a topology on the space $M_+$. This topology comes from
the identification of $M_+$ with $U(\mathfrak{g}_-)$. The space $U(\mathfrak{g}_-)$ can be represented as
a union of $U_n(\mathfrak{g}_-), n \geq 0$, where $U_n(\mathfrak{g}_-)$ is the set of all elements of $U(\mathfrak{g}_-)$ of
degree $\leq n$. Furthermore, for any $n \geq 0$, we have a linear map $\mathfrak{g}_-^* \otimes U_n(\mathfrak{g}_-)$
given by $x_1 \otimes ... \otimes x_n \rightarrow x_1 ... x_n$. This map induces a linear isomorphism $\xi_n : 
\otimes_{j=0}^n S^j \mathfrak{g}_- \rightarrow U_n(\mathfrak{g}_-)$, where $S^j \mathfrak{g}_-$ is the $j$-th symmetric power of $\mathfrak{g}_-$ (as usual we
set $\mathfrak{g}_-^* = S^0 \mathfrak{g}_- = k$). Since $S^j \mathfrak{g}_-$ has a natural weak topology, coming from its
embedding to $(\mathfrak{g}_+^*)^*$, the isomorphism $\xi_j$ defines a topology on $U_n(\mathfrak{g}_-)$. Moreover,
by the definition, if $m < n$ then $U_m(\mathfrak{g}_-)$ is a closed subspace in $U_n(\mathfrak{g}_-)$. This allows
us to equip $U(\mathfrak{g}_-)$, i.e. $M_+$, with the topology of inductive limit. By the definition,
a set $U \subset U(\mathfrak{g}_-)$ is open in this topology if and only if $U \cap U_n(\mathfrak{g}_-)$ is open for all
$n$.

Lemma 7.3. Let $g \in \mathfrak{g}$. Then $\pi_{M_+}(g)$ is a continuous operator $M_+ \rightarrow M_+$.

Proof. Let $g \in \mathfrak{g}$. We need to show that for any neighborhood of the origin $U \subset M_+$
there exists a neighborhood of the origin $U' \subset M_+$ such that $\pi_{M_+}(g)U' \subset U$.

Let $U \subset U(\mathfrak{g}_-)$ be a neighborhood of zero, and $U_n = U \cap U_n(\mathfrak{g}_-)$. To construct
$U'$, we need to construct $U'_n = U' \cap U_n(\mathfrak{g}_-)$ such that $U'_n = U_{n+1}' \cap U_n(\mathfrak{g}_-)$. Before
giving the construction of $U'_n$, we make some definitions.

For any neighborhood $U$ of zero, there exists an increasing sequence of finite
subsets $T_n \subset I$, $n \geq 1$, such that for any $f \in S^m \mathfrak{g}_-$, $m \leq n$ satisfying the equation
$f(a_{i_1}, ..., a_{i_m}) = 0$ for any $i_1, ..., i_m \in T_n$, one has $\xi_n(f) \in U$. Fix such a sequence
$\{T_n, n \geq 1\}$.

Let $I$ be as in Section 7.4. For any finite subset $J \subset I$ denote by $S(J)$ the set of
all $i \in I$ such that there exists $b \in \mathfrak{g}_-$ and $j \in J$ with the property $[bb^i](a_j) \neq 0$.
Since $[bb^i](a_j) = b \otimes b^i(\delta(a_j))$, the set $S(J)$ is finite. Let the sets $S_n(J) \subset I$ be
defined recursively by $S_0(J) = J, S_n(J) = S(S_{n-1}(J))$.

To construct $U'$, we consider separately the cases $g \in \mathfrak{g}_+$ and $g \in \mathfrak{g}_-$. First
consider the case $g \in \mathfrak{g}_+$.

For any elements $x_1, ..., x_n \in \mathfrak{g}_-$ $(n \geq 1)$ consider the element $X = \sum_{\sigma \in S_n} x_{\sigma(1)} ... x_{\sigma(n)}$ in $U_n(\mathfrak{g}_-)$, where $S_n$ is the symmetric group. Consider the element $gX \in U_{n+1}(\mathfrak{g}_-)$. It is easy to see that it is possible to write $gX$ as a linear combination of elements of the form $\sum_{\sigma \in S_m} y_{\sigma(1)} ... y_{\sigma(m)}; y_p \in \mathfrak{g}_-, 0 \leq m \leq n + 1$, in such a way that $y_p$ are
iterated commutators of $g$ and $x_1, ..., x_n$, and the number of commutators involved in each term $y_p$ does not exceed $n$.

Now we make a crucial observation.

**Claim.** Let $J \subset I$ be a finite subset. If for some $m$, $1 \leq m \leq n$, we have $x_m(a_i) = 0$, for all $i \in S_n(J)$, then every monomial $y_1...y_m$ in the symmetrized expression of $gX$ contains a factor $y_p$ such that $y_p(a_i) = 0$, $i \in J$.

**Proof.** Clear.

The construction of $U'$ is as follows. For $n \geq 1$, let $U'_n \subset U_n(g_-)$ be the span of all elements $\xi_m(f), 0 \leq m \leq n$, where $f \in S^m g_-$ are such that $f(a_{i_1}, ..., a_{i_m}) = 0$ whenever $i_1, ..., i_m \in S_n(T_{n+1})$. Also, set $U'_0 = 0$ (recall that $\{0\} \subset k$ is a neighborhood of zero since $k$ is discrete). Our observation shows that for any $X \in U'_n$, $gX \in U_{n+1}$, as desired.

Now consider the case $g \in g_+$. Let $R_0(g) \subset I$ be the set of all $i \in I$ such that $b^i(g) \neq 0$. This is a finite set. Define inductively the sets $R_n(g)$ by $R_n(g) = S(R_{n-1}(g))$.

For any finite subsets $K, J \subset I$ denote by $P(K, J)$ the set of all $i \in I$ such that there exists $j \in J$ and $k \in K$ with $[a_k b^j](a_j) \neq 0$. It is clear that if $K, J$ are finite then $P(K, J)$ is finite. Let $P_n(K, J)$ be defined inductively by $P_n(K, J) = P(K, P_{n-1}(K, J))$.

Let $n \geq 1$ be an integer, $X \in U_n(g_-)$ be as above, and $K = R_n(g)$. Consider the vector $gX_{1+} \in M_+$. Using the relations in $M_+$, we can reduce this vector to a linear combination of vectors of the form $\sum_{\sigma \in S_m} y_{\sigma_1}...y_{\sigma_m}, y_p \in g_-, 0 \leq m \leq n+1$, in such a way that $y_p$ are obtained by iterated commutation of $g$, $x_1, ..., x_n$. As before, it is easy to see that the resulting symmetrized expression will contain no more than $n$ commutators.

Now let us make a crucial observation.

**Claim.** Let $J \subset I$ be any finite subset. If for some $m$, $1 \leq m \leq n$, we have $x_m(a_i) = 0$, for all $i \in S_n(P(K, S_n(J)))$, then every monomial $y_1...y_m$ in the symmetrized expression of $gX_{1+}$ contains a factor $y_p$ such that $y_p(a_i) = 0$, $i \in J$.

**Proof.** Clear.

The construction of $U'$ is as follows. For $n \geq 1$, let $U'_n \subset U_n(g_-)$ be the span of all elements $\xi_m(f), f \in S^m g_-, 0 \leq m \leq n$, such that $f(a_{i_1}, ..., a_{i_m}) = 0$ whenever $i_1, ..., i_m \in S_n(P(K, S_n(T_{n+1})))$. Also, set $U'_0 = 0$. Our observation shows that for any $X \in U'_n$, $gX \in U_{n+1}$, as desired. □

Consider the vector space $M_+^*$ of continuous linear functionals on $M_+$. By the definition, $M_+^*$ is naturally isomorphic to the projective limit of $U_n(g_-)^*$ as $n \to \infty$. As vector spaces, $U_n(g_-)^* = (S^i g_-)^* = S^i g_+$. Therefore, it is natural to put the discrete topology on $U_n(g_-)^*$. This equips the module $M_+^*$ with a natural structure of a complete vector space. It is also equipped with a filtration by subspaces $(M_+^*)_n = U_{n-1}(g_-)^{\perp}, n \geq 1$, such that $M_+ = \lim \frac{M_+^*}{(M_+^*)_n}$.

**Remark.** The topology of projective limit on $M_+^*$ does not, in general, coincide with the weak topology of the dual. In fact, it is stronger than the weak topology.

By Lemma 7.3, $M_+^*$ has a natural structure of a $g$-module. Namely, the action of $g$ on $M_+^*$ is defined to be the dual to the action of $g$ on $M_+$.

**Lemma 7.4.** $M_+^*$ is an equicontinuous $g$-module.

**Proof.** It is easy to see that $a(M_+^*)_n \subset (M_+^*)_n, a \in g_+$, and $b(M_+^*)_n \subset (M_+^*)_n$, $b \in g_-$. This means that the operators $\pi_{M_+^*}(g)$ are continuous for any $g \in g$, and
π_{M_+}(g) \subset \text{End}M_+^\ast is an equicontinuous family of operators. It remains to show that the assignment \( g \to \pi_{M_+}(g) \) is continuous for \( g \in g \). Since \( g_+ \) is discrete, it is enough to check this statement for \( g \in g_- \).

Let \( f \in M_+^\ast \). Let \( f_n \) be the reduction of \( f \) modulo \((M_+^\ast)_n \). We can regard \( f \) as an element of \( \bigoplus_{j=0}^n S^j g_+ \). Let us write \( f_n \) in terms of the basis \( \{a_i\} \), and let \( T_n(f) \) be the set of all \( i \in I \) such that \( a_i \) is involved in this expression.

Let \( S_n(J) \) be as in the proof of Lemma 7.3, and \( i \in I \setminus S_n(T_{n+1}(f)) \). Then it is easy to see that \( b^i f \in (M_+^\ast)_n \). This shows that for any \( n \geq 0 \) and any \( f \in M_+^\ast \), \( b^i f \in (M_+^\ast)_n \) for almost all \( i \in I \).

Thus, \( M_+^\ast \) is an equicontinuous \( g \)-module. \( \square \)

**Remark.** If \( g_+ \) is infinite dimensional then \( M_+ \) is not, in general, an equicontinuous \( g \)-module, since the family of operators \( \{\pi_{M_+}(g), g \in g_+\} \) may fail to be equicontinuous.

### 7.6. The Casimir element

Consider the tensor product \( a \otimes a^\ast \). This space can be embedded into \( \text{End}a \), by \( (x \otimes f)(y) = f(y)x, \) \( x, y \in a, f \in a^\ast \). This embedding defines a topology on \( a \otimes a^\ast \), obtained by restriction of the weak topology on \( \text{End}a \). Let \( a \hat{\otimes} a^\ast \) be the completion of \( a \otimes a^\ast \) in this topology. Since the image of \( a \otimes a^\ast \) is dense in \( \text{End}a \), this completion is identified with \( \text{End}a \).

**Lemma 7.5.** Let \( V, W \in M_0^\ast \). The map \( \pi_V \otimes \pi_W : a \otimes a^\ast \to \text{End}(V \hat{\otimes} W) \) extends to a continuous map \( a \hat{\otimes} a^\ast \to \text{End}(V \hat{\otimes} W) \).

**Proof.** Let \( x \in V \hat{\otimes} W \) be a vector. It is easy to see that the map \( \pi_V \otimes \pi_W(\cdot)x : a \otimes a^\ast \to V \hat{\otimes} W \) is continuous. Since the space \( V \hat{\otimes} W \) is complete, this map extends to a continuous map \( a \hat{\otimes} a^\ast \to V \hat{\otimes} W \). This allows us to define a linear map \( \pi_V \otimes \pi_W : a \hat{\otimes} a^\ast \to \text{End}(V \hat{\otimes} W) \). We would like to show that this map is continuous.

Let \( x \in V \hat{\otimes} W \) be a vector, and \( n \geq 0 \) be an integer. Let \( P \subset V \hat{\otimes} W \) be an open subspace, and \( U = \{A \in \text{End}(V \hat{\otimes} W) : Ax \in P\} \). Since open sets of this form generate the topology on \( \text{End}(V \hat{\otimes} W) \), it is enough to show that there exists a neighborhood of zero \( Y \subset a \hat{\otimes} a^\ast \) such that \( (\pi_V \otimes \pi_W)(Y) \subset U \), i.e. \( (\pi_V \otimes \pi_W)(Y)x \subset P \).

We can assume that \( P = V_1 \hat{\otimes} W_1 + W_1 \hat{\otimes} V \), where \( V_1, W_1 \) are open subspaces of \( V, W \). By the equicontinuity of \( \pi_V(g), \pi_W(g), g \in g \), there exist open subspaces \( V_2 \subset V, W_2 \subset W \) such that \( \pi_V(g)V_2 \subset V_1, \pi_W(g)W_2 \subset W_1 \). Let \( y \in V \otimes W \) be a vector in the usual tensor product of \( V \) and \( W \) such that \( y - x \in V_2 \hat{\otimes} W + W \hat{\otimes} W_2 \). Then for any \( t \in a \hat{\otimes} a^\ast \), \( (\pi_V \otimes \pi_W)(t)(y - x) \in P \), so it is enough to find \( Y \) satisfying the condition \( (\pi_V \otimes \pi_W)(Y)y \subset P \).

We have \( y = \sum_{j=1}^m v_j \otimes w_j, v_j \in V, w_j \in W \). Let \( X \subset a \) be a finite-dimensional subspace such that for any \( b \in X^\perp \subset a^\ast \), \( bw_j \in W_1 \) for \( j = 1, \ldots, m \). Such a subspace exists by Lemma 7.1. The set \( Y = a \hat{\otimes} X^\perp \) (the completion of \( a \otimes X^\perp \) in \( a \hat{\otimes} a^\ast \)) is open in \( a \hat{\otimes} a^\ast \), and \( (\pi_V \otimes \pi_W)(Y)y \subset P \), as desired. This shows the continuity of \( \pi_V \otimes \pi_W \) on \( a \hat{\otimes} a^\ast \). \( \square \)

Let \( r \in a \hat{\otimes} a^\ast \) be the vector corresponding to the identity operator under the identification \( a \hat{\otimes} a^\ast \) with \( \text{End}a \). Let \( r^\text{op} \in a^\ast \hat{\otimes} a \) be the element obtained from \( r \) by permutation of the components. We define the Casimir element \( \Omega \in a \hat{\otimes} a^\ast + a^\ast \hat{\otimes} a \) to be the sum \( r + r^\text{op} \).

It is easy to see that, \( r = \sum a_i \otimes b^i, r^\text{op} = \sum b^i \otimes a_i, \Omega = \sum (a_i \otimes b^i + b^i \otimes a_i) \).
Let $V, W$ be equicontinuous $g$-modules, and denote by $\pi_V : g \rightarrow \text{End} V$, $\pi_W : g \rightarrow \text{End} W$ the corresponding linear maps. Let $\Omega_{VW} = \pi_V \otimes \pi_W(\Omega)$. This endomorphism of $V \otimes W$ is well defined and continuous by Lemma 7.5. Moreover, it is easy to see that $\Omega_{VW}$ commutes with $g$, so it is an endomorphism of $V \otimes W$ as an equicontinuous $g$-module.

**Remark.** Although the Casimir operator $\Omega = \sum (a_i \otimes b^i + b^i \otimes a_i)$ is defined in the product of any two equicontinuous $g$-modules $V \otimes W$, the Casimir element $C = \sum (a_i b^i + b_i a_i)$ in general (for $\dim a = \infty$) has no meaning as an operator in an equicontinuous $g$-module $V$.

7.7. Drinfeld category. Let $\mathcal{M}^e$ denote the category whose objects are equicontinuous $g$-modules, and $\text{Hom}_{\mathcal{M}}(U, W) = \text{Hom}_g(U, W)[[h]]$. This is an additive category. For brevity we will later write $\text{Hom}$ for $\text{Hom}_{\mathcal{M}}$.

Define a structure of a braided monoidal category on $\mathcal{M}^e$ analogously to Section 1.4, using an associator $\Phi$ and the functor $\hat{\gamma}$. As before, we identify $\mathcal{M}^e$ with a strict category and forget about positions of brackets.

Let $\gamma$ be the functorial isomorphism defined by $\gamma_{XY} = \beta_{YX}^{-1} \in \text{Hom}(X \otimes Y, Y \otimes X)$, $X, Y \in \mathcal{M}^e$. It is easy to check that $\gamma$ is a braiding on $\mathcal{M}^e$. We will need the braiding $\gamma$ in our construction below.

8. The fiber functor.

8.1. The category of complete $k[[h]]$-modules.

Let $V$ be a complete vector space over $k$. Then the space $V[[h]] = V \hat{\otimes} k[[h]]$ of formal power series in $h$ with coefficients in $V$ is also a complete vector space. Moreover, $V[[h]]$ has a natural structure of a topological $k[[h]]$-module. We call a topological $k[[h]]$-module complete if it is isomorphic to $V[[h]]$ for some complete $V$.

Let $\mathcal{A}^e$ be the category of complete $k[[h]]$-modules, where morphisms are continuous $k[[h]]$-linear maps. It is an additive category. Define the tensor structure on $\mathcal{A}^e$ as follows. For $V, W \in \mathcal{A}^e$ define $V \hat{\otimes} W$ to be the quotient of the completed tensor product $V \hat{\otimes} W$ by the image of the operator $h \otimes 1 - 1 \otimes h$. It is clear that $V, W \in \mathcal{A}^e$, $V \hat{\otimes} W$ is also in $\mathcal{A}^e$. The category $\mathcal{A}^e$ equipped with the functor $\hat{\otimes}$ is a symmetric monoidal category.

Let $\text{CVect}$ be the category of complete vector spaces. We have the functor of extension of scalars, $V \mapsto V[[h]]$, acting from $\text{CVect}$ to $\mathcal{A}^e$. This functor respects the tensor product, i.e. $(V \hat{\otimes} W)[[h]]$ is naturally isomorphic to $V[[h]] \hat{\otimes} W[[h]]$.

8.2. Properties of the Verma modules.

Let $(g, g^+, g^-)$ be a Manin triple, and $\mathcal{M}^e$ be the Drinfeld category associated to $g$. Let $M_+, M_-$ be the Verma modules over $g$ defined in Section 7.5.

Recall that the modules $M_\pm$ are identified with $U(g_\pm)$. Thus, we can define the maps $i_\pm : M_\pm \rightarrow M_\pm \otimes M_\pm$ given by comultiplication in the universal enveloping algebras $U(g_\pm)$. These maps are $U(g)$-intertwiners, since they are $U(g_{\pm})$-intertwiners and map the vector $1_\pm$ to the $g_\pm$-invariant vector $1_\pm \otimes 1_\pm$.

Let $M_+^*$ be as in Section 7.5, and $f, g \in M_+^*$. Consider the linear functional $M_+ \rightarrow k$ defined by $v \mapsto (f \otimes g)(i_+(v))$. It is easy to check that this functional is continuous, so it belongs to $M_+^*$. Define the map $i_+^* : M_+^* \otimes M_+^* \rightarrow M_+^*$ by $i_+^*(f \otimes g)(v) = (f \otimes g)(i_+(v))$, $v \in M_+$. It is clear that $i_+^*$ is continuous, so it extends to a morphism in $\mathcal{M}^e$: $i_+^* : M_+^* \otimes M_+^* \rightarrow M_+^*$.

Let $V \in \mathcal{M}$. Consider the space $\text{Hom}_g(M_-, M_+^* \hat{\otimes} V)$, where $\text{Hom}_g$ denotes the
set of continuous homomorphisms. Equip this space with the weak topology (see Section 7.1).

**Lemma 8.1.** The complete vector space \( \text{Hom}_k(M_-, M^+_+ \hat{\otimes} V) \) is isomorphic to \( V \). The isomorphism is given by \( f \to (1_+ \otimes 1)(f(1_-)), f \in \text{Hom}_k(M_-, M^+_+ \hat{\otimes} V) \).

**Proof.** By the Frobenius reciprocity, \( \text{Hom}_k(M_-, M^+_+ \hat{\otimes} V) \) is isomorphic, as a topological vector space, to the space of invariants \( (M^+_+ \hat{\otimes} V)^{g_-} \), via \( f \to f(1_-) \). Consider the space \( \text{Hom}_k(M_+, V) \) of continuous homomorphisms from \( M_+ \) to \( V \), equipped with the weak topology, and the map \( \phi : (M^+_+ \hat{\otimes} V) \to \text{Hom}_k(M_+, V) \), given by \( \phi(f \otimes v)(x) = f(x)v, u \in M^+_+, x \in M_+, v \in V \). It is clear that \( \phi \) is injective and continuous.

**Claim.** The map \( \phi \) restricts to an isomorphism \((M^+_+ \hat{\otimes} V)^{g_-} \to \text{Hom}_k(M_+, V)\).

**Proof.** It is clear that \( \phi((M^+_+ \hat{\otimes} V)^{g_-}) \subset \text{Hom}_k(M_+, V) \). So it is enough to show that any continuous \( g_- \)-intertwiner \( g : M_+ \to V \) is of the form \( \phi(g') \), \( g' \in (M^+_+ \hat{\otimes} V)^{g_-} \), where \( g' \) continuously depends on \( g \).

Let \( X \subset V \) be an open subspace. Then for any \( g_- \)-intertwiner \( g : M_+ \to V \) and \( n \geq 1 \) the image of \( g(U_n(g_-)1_+) \) in \( V/V_m \) is finite-dimensional. This shows that \( g = \phi(g') \) for some \( g' \in (V \otimes M^+_+)^{g_-} \). It is clear that \( g' \) is continuous in \( g \). The claim is proved.

By the Frobenius reciprocity, the space \( \text{Hom}_k(M_+, V) \) is isomorphic to \( V \) as a topological vector space, via \( f \to f(1_+) \). The lemma is proved. \( \square \)

**8.3. The forgetful functor.**

Let \( F : \mathcal{M}^e \to \mathcal{A}^c \) be a functor given by \( F(V) = \text{Hom}(M_-, M^+_+ \hat{\otimes} V) \). Lemma 8.1 implies that this functor is naturally isomorphic to the “forgetful” functor which associates to every equicontinuous \( g \)-module \( M \) the complete \( k[[h]] \)-module \( M[[h]] \). The isomorphism between these two functors is given by \( f \to (1_+ \otimes 1)(f(1_-)) \), for any \( f \in F(M) \). Denote this isomorphism by \( \tau \).

**8.4. Tensor structure on the functor \( F \).**

From now on, when no confusion is possible, we will denote the tensor product in the categories \( \mathcal{M}^e \) and \( \mathcal{A}^c \) by \( \otimes \), instead of \( \hat{\otimes} \) and \( \tilde{\otimes} \).

Define a tensor structure on the functor \( F \) constructed in Section 8.3.

For any \( v \in F(V), w \in F(W) \) define \( J_{VW}(v \otimes w) \) to be the composition of morphisms:

\[
M_- \xrightarrow{i_-} M_- \otimes M_- \xrightarrow{v \otimes w} M^+_+ \hat{\otimes} V \otimes M^+_+ \hat{\otimes} W \xrightarrow{1 \otimes \gamma_{23} \otimes 1} M^+_+ \hat{\otimes} V \hat{\otimes} W,
\]

(8.1)

where \( \gamma_{23} \) denotes the braiding \( \gamma \) acting in the second and third components of the tensor product. That is,

\[
J_{VW}(v \otimes w) = (i^*_+ \otimes 1 \otimes 1) \circ (1 \otimes \gamma_{23} \otimes 1) \circ (v \otimes w) \circ i_-.
\]

**Proposition 8.2.** The maps \( J_{VW} \) are isomorphisms and define a tensor structure on the functor \( F \).

**Proof.** It is obvious that \( J_{VW} \) is an isomorphism since it is an isomorphism modulo \( h \).
To prove the associativity of $J_{V,W}$, we need the following result.

**Lemma 8.3** $(i_- \otimes 1) \circ i_- = (1 \otimes i_-) \circ i_-$ in $\text{Hom}(M_-, M_-^3)$; $(i_+^* \otimes 1) \circ i_+^* = (1 \otimes i_+^*) \circ i_+^*$ in $\text{Hom}(M_+^*, (M_+^*)^3$).

**Proof.** The proof of the first identity coincides with the proof of Lemma 2.3 in Part I. To prove the second identity, define $M_+^* \hat{\otimes} M_+^* \hat{\otimes} M_+^*$ to be space of continuous linear functionals on $M_+^* \hat{\otimes} M_+^* \hat{\otimes} M_+^*$. Since the operators $\Omega_{ij} \in \text{End}_g(M_+^* \hat{\otimes} M_+^* \hat{\otimes} M_+^*)$ are continuous, one can define the dual operators $\Omega_{ij}^* \in \text{End}_g(M_+^* \hat{\otimes} M_+^* \hat{\otimes} M_+^*)$, and hence the operator $\Phi^*$ dual to $\Phi$. It is easy to show analogously to the proof of Lemma 2.3 that $\Phi^*(1_+ \otimes 1_+ \otimes 1_+) = 1_+ \otimes 1_+ \otimes 1_+$, which implies the second identity of Lemma 8.3.

Now we can finish the proof of the proposition. We need to show that for any $v \in F(V), w \in F(W), u \in F(U) \ J_{V \otimes W,U} \circ (J_{V,W} \otimes 1)(v \otimes w \otimes u) = J_{V,W \otimes U} \circ (1 \otimes J_{W,U})(v \otimes w \otimes u)$, i.e.

$$(i_+^* \otimes 1 \otimes 1 \otimes 1) \circ \gamma_{34,5} \circ (i_+^* \otimes 1 \otimes 1 \otimes 1 \otimes 1) \circ \gamma_{23} \circ (v \otimes w \otimes u) \circ (i_- \otimes 1) \circ i_- = \gamma_{34,5} \circ \gamma_{23} = (i_+^* \otimes 1 \otimes 1 \otimes 1) \circ \gamma_{23} \circ (1 \otimes 1 \otimes i_+^* \otimes 1 \otimes 1) \circ \gamma_{45} \circ (v \otimes w \otimes u) \circ (1 \otimes i_-) \circ i_- = (i_+^* \otimes 1 \otimes 1 \otimes 1 \otimes 1) \circ \gamma_{23} \circ (1 \otimes 1 \otimes i_+^* \otimes 1 \otimes 1) \circ \gamma_{45},$$

in $\text{Hom}(M_+^* \otimes V \otimes M_+^* \otimes W \otimes M_+^* \otimes U, M_+^* \otimes V \otimes W \otimes U)$.

To prove this equality, we observe that the functoriality of the braiding implies the identity

$$(i_+^* \otimes 1 \otimes 1 \otimes 1 \otimes 1) \circ (i_+^* \otimes 1 \otimes 1 \otimes 1 \otimes 1) \circ \gamma_{34,5} \circ \gamma_{23} = (i_+^* \otimes 1 \otimes 1 \otimes 1 \otimes 1) \circ \gamma_{23} \circ (1 \otimes 1 \otimes i_+^* \otimes 1 \otimes 1) \circ \gamma_{45},$$

in $\text{Hom}(M_+^* \otimes V \otimes M_+^* \otimes W \otimes M_+^* \otimes U, M_+^* \otimes V \otimes W \otimes U)$.

Using (8.5) and the identity $(i_+^* \otimes 1) \circ i_+^* = (1 \otimes i_+^*) \circ i_+^*$, which follows from Lemma 8.3, we reduce (8.4) to the identity $\gamma_{34,5} \gamma_{23} = \gamma_{2,23} \gamma_{23}$, which follows directly from the braiding axioms. \qed

We will call the functor $F$ equipped with the tensor structure defined above the fiber functor.

9. Quantization of Lie bialgebras.

9.1. The algebra of endomorphisms of the fiber functor.

Let $H = \text{End}(F)$ be the algebra of endomorphisms of the functor $F$, with a topology defined by the ideal $hH \subset H$. It is clear that $H$ is a topological algebra over $k[[h]]$ (see Part I, Section 3.1).

Let $H_0$ be the algebra of endomorphisms of the forgetful functor $\mathcal{M}_0^e \to \text{CVect}$. It follows from Lemma 8.1 that the algebra $H$ is naturally isomorphic to $H_0[[h]]$.

Let $F^2 : \mathcal{M}^e \times \mathcal{M}^e \to \mathcal{A}^e$ be the bifunctor defined by $F^2(V,W) = F(V) \otimes F(W)$.

Let $H^2 = \text{End}(F^2)$. It is clear that $H^2 \supset H \otimes H$ but $H^2 \neq H \otimes H$ unless $g$ is finite dimensional.
The algebra $H$ has a natural “comultiplication” $\Delta : H \to H^2$ defined by
$\Delta(a)_{V,W}(v \otimes w) = J^{-1}_{V,W}a_{V\otimes W}J_{V,W}(v \otimes w)$, $a \in H$, $v \in F(V), w \in F(W)$ where $a_{V}$ denotes the action of $a$ in $F(V)$. We can also define the counit on $H$ by $\varepsilon(a) = a_1 \in k[[h]]$, where $1$ is the neutral object.

A topological algebra $A$ over $k[[h]]$ is said to be a topological bialgebra if it is equipped with a coproduct $\Delta : A \to A \otimes A$ (where $\otimes$ is the tensor product in $A$) and a counit $\varepsilon : A \to k[[h]]$ which are $k[[h]]$-linear, continuous, and satisfy the standard axioms of a bialgebra.

We will need the following statement.

**Proposition 9.1.** Let $A \subset H$ be a topological subalgebra such that $\Delta(A) \subset A \otimes A$. Then $(A, \Delta, \varepsilon)$ is a topological bialgebra over $k[[h]]$.

The proof is straightforward.

**Remark.** For infinite-dimensional $\mathfrak{g}$, the algebra $H$ equipped with the topology defined by the ideal $hH$ is not a topological bialgebra since $\Delta(H)$ is not a subset of $H \otimes H$.

In the following sections we construct a quantum universal enveloping algebra $U_h(\mathfrak{g}_+)$, which is a quantization of the Lie bialgebra $\mathfrak{g}_+$, in the sense of Drinfeld (see [Dr1] and Part I, Section 3.1). Namely, the algebra $U_h(\mathfrak{g}_+)$ is obtained as a subalgebra of $H$ such that $\Delta(A) \subset A \otimes A$.

**9.2. The algebra $U_h(\mathfrak{g}_+)$.**

Let $x \in F(M_-)$. Define the endomorphism $m_+(x)$ of the functor $F$ as follows. For any $V \in \mathcal{M}^e$, $v \in F(V)$, define the element $m_+(x)v \in F(V)$ to be the composition of the following morphisms in $\mathcal{M}^e$: $m_+(x)v = (i_+^* \otimes 1) \circ (1 \otimes v) \circ x$. This defines a linear map $m_+ : F(M_-) \to H$. Denote the image of this map by $U_h(\mathfrak{g}_+)$. It is easy to see that for any $a \in U(\mathfrak{g}_+) \tau(m_+(a1_-)v) \equiv a\tau(v) \mod h$, which implies that $m_+$ is an embedding.

**Proposition 9.2.** $U_h(\mathfrak{g}_+)$ is a subalgebra in $H$.

**Proof.**

Using Lemma 8.3, for any $x, y \in F(M_-), V \in \mathcal{M}^e, v \in F(V)$ we obtain

$$m_+(x)m_+(y)v = (i_+^* \otimes 1) \circ (1 \otimes i_+^* \otimes 1) \circ (1 \otimes 1 \otimes v) \circ (1 \otimes y) \circ x =$$

$$(i_+^* \otimes 1) \circ (i_+^* \otimes 1 \otimes 1) \circ (1 \otimes 1 \otimes v) \circ (1 \otimes y) \circ x =$$

$$(i_+^* \otimes 1) \circ (1 \otimes v) \circ (i_+^* \otimes 1) \circ (1 \otimes y) \circ x =$$

$$(i_+^* \otimes 1) \circ (1 \otimes v) \circ z,$$

where $z = (i_+^* \otimes 1) \circ (y \otimes 1) \circ x \in F(M_-)$.

So by the definition we get $m_+(x) \circ m_+(y) = m_+(z)$. □

Note that the algebra $U_h(\mathfrak{g}_+)$ is a deformation of the algebra $U(\mathfrak{g}_+)$. Indeed, we can define a linear isomorphism $\mu : U(\mathfrak{g}_+)[[h]] \to U_h(\mathfrak{g}_+) \mu(a) = m_-(a1_-)$, $a \in U(\mathfrak{g}_+)[[h]]$. This isomorphism has the property $\mu(ab) = \mu(a) \circ \mu(b) \mod h^2$, which follows from the fact that $\Phi \equiv 1 \mod h$, but in general $\mu(ab) \neq \mu(a) \circ \mu(b)$.

The subalgebra $U_h(\mathfrak{g}_+)$ has a unit which is equal to $\mu(1), 1 \in U(\mathfrak{g}_+)$. To check this, it is enough to observe that $\mu(1)$ is invertible and check the identity $\mu(1)^2 = \mu(1)$.

**9.3. The coproduct on $U_h(\mathfrak{g}_+)$.**
Proposition 9.3. The algebra $U_h(\mathfrak{g}^+)$ is closed under the coproduct $\Delta$, i.e. $\Delta(U_h(\mathfrak{g}^+)) \subset U_h(\mathfrak{g}^+) \otimes U_h(\mathfrak{g}^+)$, and for any $x \in F(M_-)$ one has

$$\Delta(m_+(x)) = (m_+ \otimes m_+)(J_{M_-M_-}^{-1}((1 \otimes i_-) \circ x)).$$

Proof. Let $x \in F(M_-)$, $V, W \in \mathcal{M}^e$, $v \in V$, $w \in W$. By the definition of $\Delta$ and $m_+$, the element $\Delta(m_+(x)) \in H^2$ is uniquely determined by the identity

$$\begin{align*}
(i_+^* \otimes 1 \otimes 1) & \circ (1 \otimes i_+^* \otimes 1 \otimes 1) \circ \gamma_{34} \circ (1 \otimes v \otimes w) \circ R(1 \otimes i_-) \circ x = \\
(i_+^* \otimes 1 \otimes 1) & \circ \gamma_{23} \circ \Delta(m_+(x))(v \otimes w) \circ i_-
\end{align*}$$

in $F(V \otimes W)$.

The element $X = J_{M_-M_-}^{-1}((1 \otimes i_-)x) \in F(M_-) \otimes F(M_-)$ is, by the definition, uniquely determined by the identity

$$\begin{align*}
(1 \otimes i_-) & \circ x = (i_+^* \otimes 1 \otimes 1) \circ \gamma_{23} \circ X \circ i_-
\end{align*}$$

in $F(M_- \otimes M_-)$. Therefore, to prove formula (9.2), it is enough to prove the equality obtained by substitution of $(i_+^* \otimes 1 \otimes i_+^* \circ 1) \circ (1 \otimes v \otimes 1 \otimes w) \circ X$ instead of $\Delta(m_+(x))(v \otimes w)$ in (9.3):

$$\begin{align*}
(i_+^* \otimes 1 \otimes 1) & \circ (1 \otimes i_+^* \otimes 1 \otimes 1) \circ \gamma_{34} \circ (1 \otimes v \otimes w) \circ (1 \otimes i_-) \circ x = \\
(i_+^* \otimes 1 \otimes 1) & \circ \gamma_{23} \circ (i_+^* \otimes 1 \otimes i_+^* \circ 1) \circ (1 \otimes v \otimes 1 \otimes w) \circ X \circ i_-
\end{align*}$$

in $F(V \otimes W)$.

Using the functoriality of the braiding and Lemma 8.3, we obtain

$$\begin{align*}
(i_+^* \otimes 1 \otimes 1) & \circ \gamma_{23} \circ (i_+^* \otimes 1 \otimes i_+^* \circ 1) \circ (1 \otimes v \otimes 1 \otimes w) = \\
(i_+^* \otimes 1 \otimes 1) & \circ \gamma_{23} \circ (i_+^* \otimes 1 \otimes i_+^* \circ 1) \circ \gamma_{23,4}^{-1} \circ (1 \otimes v \otimes 1 \otimes w) \circ \gamma_{23} = \\
(i_+^* \otimes 1 \otimes 1) & \circ (i_+^* \otimes i_+^* \circ 1 \otimes 1) \circ \gamma_{3,4} \circ \gamma_{23,4}^{-1} \circ (1 \otimes 1 \otimes v \otimes w) \circ \gamma_{23} = \\
(i_+^* \otimes 1 \otimes 1) & \circ (i_+^* \otimes i_+^* \circ 1 \otimes 1) \circ \gamma_{45} \circ \gamma_{23,4}^{-1} \circ (1 \otimes 1 \otimes v \otimes w) \circ \gamma_{23} = \\
(i_+^* \otimes 1 \otimes 1) & \circ (i_+^* \otimes 1 \otimes 1 \otimes 1) \circ (1 \otimes i_+^* \otimes 1 \otimes 1 \otimes 1) \circ \gamma_{45} \circ \gamma_{23,4}^{-1} \circ (1 \otimes 1 \otimes v \otimes w) \circ \gamma_{23}
\end{align*}$$

in $\text{Hom}(M_+^* \otimes M_-^* \otimes M_+^* \otimes M_-^* \otimes V \otimes W)$. It is easy to see that $i_+^* \circ \gamma = i_+^*$, so using Lemma 8.3 again, we get from (9.6):

$$\begin{align*}
(i_+^* \otimes 1 \otimes 1) & \circ \gamma_{23} \circ (i_+^* \otimes 1 \otimes i_+^* \circ 1) \circ (1 \otimes v \otimes 1 \otimes w) = \\
(i_+^* \otimes 1 \otimes 1) & \circ (1 \otimes i_+^* \otimes 1 \otimes 1) \circ \gamma_{34} \circ (1 \otimes v \otimes w) \circ (i_+^* \otimes 1 \otimes 1) \circ \gamma_{23}
\end{align*}$$

Substituting (9.7) into the right hand side of (9.5) and using (9.4), we get

$$\begin{align*}
(i_+^* \otimes 1 \otimes 1) & \circ \gamma_{23} \circ (i_+^* \otimes 1 \otimes i_+^* \circ 1) \circ (1 \otimes v \otimes 1 \otimes w) \circ X \circ i_- = \\
(i_+^* \otimes 1 \otimes 1) & \circ (1 \otimes i_+^* \otimes 1 \otimes 1) \circ \gamma_{34} \circ (1 \otimes v \otimes w) \circ (i_+^* \otimes 1 \otimes 1) \circ \gamma_{23} \circ X \circ i_- = \\
(i_+^* \otimes 1 \otimes 1) & \circ (1 \otimes i_+^* \otimes 1 \otimes 1) \circ \gamma_{34} \circ (1 \otimes v \otimes w) \circ (1 \otimes i_-) \circ x
\end{align*}$$

in $F(V \otimes W)$, which proves (9.2). The proposition is proved. $\square$
Corollary 9.4. The algebra $U_h(\mathfrak{g}_+)$, equipped with the coproduct $\Delta$, is a quantized universal enveloping algebra.

Proof.. It follows from Lemma 9.1 and Propositions 9.2, 9.3 that $U_h(\mathfrak{g}_+)$ is a topological bialgebra over $k[[h]]$ isomorphic to $U(\mathfrak{g}_-)[[h]]$ as a topological $k[[h]]$-module, and such that $U_h(\mathfrak{g}_+)/hU_h(\mathfrak{g}_+)$ is isomorphic to $U(\mathfrak{g}_+)$ as a bialgebra. This implies that $U_h(\mathfrak{g})$ has an antipode, because the antipode exists mod$h$. Thus, $U_h(\mathfrak{g}_+)$ is a quantized universal enveloping algebra. □

9.4. The algebra $U_h(\mathfrak{g}_+)$ is a quantization of $\mathfrak{g}_+$.

Proposition 9.5. The algebra $U_h(\mathfrak{g}_+)$ is a quantization of the Lie bialgebra $\mathfrak{g}_+$.

Proof. Let $x \in U_h(\mathfrak{g}_+)$ be such that there exists $x_0 \in \mathfrak{g}_+ \subset U(\mathfrak{g}_+)$ satisfying the condition $x \equiv x_0 \mod h$.

It is easy to show that for any $V, W \in M$

(9.9) $\tau_{V \otimes W}^{-1} \circ J_{VW} \circ (\tau_V \otimes \tau_W) = 1 + hr/2 + O(h^2)$

in End$(V \otimes W)$. From (9.9) and the definition of coproduct, analogously to the proof of Proposition 3.6 in Part I, it is easy to obtain the congruence

(9.10) $h^{-1}(\Delta(x) - \Delta^{op}(x)) \equiv \delta(x_0) \mod h$.

which means that $U_h(\mathfrak{g}_+)$ is the quantization of $\mathfrak{g}_+$. □

Thus, we have proved the following theorem, which answers question 1.1 in [Dr3].

Theorem 9.6. Let $\mathfrak{a}$ be a Lie bialgebra over $k$. Then there exists a quantized universal enveloping algebra $U_h(\mathfrak{a})$ over $k$ which is a quantization of $\mathfrak{a}$.

9.5. The isomorphism between two constructions of the quantization.

Let us compare the results of the previous sections to the results of Part I. In Part I, we showed the existence of quantization for any finite dimensional Lie bialgebra. Let $(\mathfrak{g}, \mathfrak{g}_+, \mathfrak{g}_-)$ be a finite-dimensional Manin triple. Let $U_h(\mathfrak{g}_+)$ denote the quantization of $\mathfrak{g}_+$ constructed in this section, and by $\tilde{U}_h(\mathfrak{g}_+)$ the quantization constructed in Part I.

Proposition 9.7. The quantized universal enveloping algebras $U_h(\mathfrak{g}_+), \tilde{U}_h(\mathfrak{g}_+)$ are isomorphic.

(Note added on May 19, 2016: Adrien Brochier has discovered that the proof of Proposition 9.7 given below contains an error, namely the morphism $\chi$ is defined incorrectly. A corrected proof with the right definition of $\chi$ appears in [Br], Subsection 2.2).

Proof. If $\mathfrak{g}$ is finite-dimensional, then $M_+$ is an equicontinuous $\mathfrak{g}$-module. Let $\tilde{F} : \mathcal{M}^e \to \mathcal{A}^c$ be the functor defined by $\tilde{F}(V) = \text{Hom}(M_+ \otimes M_-, V), V \in \mathcal{M}^e$.

The tensor structure on $\tilde{F}$ can be defined as in Part I.

Let $\sigma \in \text{Hom}(1, M_+^e \otimes M_+^e)$ be the canonical element. Consider the morphism $\chi : \tilde{F} \to F$, defined as follows. For any $V \in M$, $v \in \tilde{F}(V)$, define $\chi_V(v) \in F(V)$ as the composition $\chi_V(v) = (1 \otimes v) \circ (\sigma \otimes 1)$. It is obvious that $\chi$ is an isomorphism of additive functors.

Claim. $\chi$ is an isomorphism of tensor functors.
Proof. The statement is equivalent to the identity

\[(1 \otimes v \otimes w) \circ \beta_{34} \circ (1 \otimes i_+ \otimes i_-) \circ (\sigma \otimes 1) = (i_+^* \otimes 1 \otimes 1) \circ \gamma_{23} \circ (1 \otimes v \otimes 1 \otimes w) \circ (\sigma \otimes 1 \otimes \sigma \otimes 1) \circ i_- \]

(9.11)

which should be satisfied in \(\text{Hom}(M_-, M^*_+ \otimes V \otimes W)\) for any \(V, W \in \mathcal{M}^e\), \(v \in \tilde{F}(V)\), \(w \in \tilde{F}(W)\). Using the identity \((1 \otimes v \otimes 1 \otimes w) \circ \gamma_{23} = \gamma_{23,4} \circ (1 \otimes 1 \otimes v \otimes w)\), we reduce (9.11) to the identity

\[\beta_{34} \circ (1 \otimes i_+ \otimes i_-) \circ (\sigma \otimes 1) = (i_+^* \otimes 1 \otimes 1 \otimes 1 \otimes 1) \circ \gamma_{23,4} \circ (\sigma \otimes 1 \otimes \sigma \otimes 1) \circ i_-\]

(9.12)

in \(\text{Hom}(M_-, M^*_+ \otimes M_+ \otimes M_- \otimes M_+ \otimes M_-)\). Moving \(\beta_{34}\) from left to right and interchanging \(\beta_{34}^{-1}\) with \(i_+^* \otimes 1 \otimes 1 \otimes 1 \otimes 1\), so that (9.12) is equivalent to the identity:

\[(1 \otimes i_+ \otimes i_-) \circ (\sigma \otimes 1) = (i_+^* \otimes 1 \otimes 1 \otimes 1 \otimes 1) \circ \beta_{34}^{-1} \gamma_{23,4} \circ (\sigma \otimes 1 \otimes \sigma \otimes 1) \circ i_-\]

(9.13)

in \(\text{Hom}(M_-, M^*_+ \otimes M_+ \otimes M_- \otimes M_+ \otimes M_-)\). It is clear that \(\gamma_{1,23} \circ (1 \otimes \sigma) = \sigma \otimes 1\) in \(\text{Hom}(M_-, M_- \otimes M^*_+ \otimes M_+)\). Therefore, using the relations \(\gamma_{23,4} \gamma_{3,45}^{-1} = \gamma_{23} \gamma_{45}^{-1}\), and \(\beta \gamma = 1\), we reduce (9.13) to

\[(1 \otimes i_+) \circ \sigma = (i_+^* \otimes 1 \otimes 1) \circ \gamma_{23} \circ (\sigma \otimes \sigma)\]

(9.14)

in \(\text{Hom}(1, M^*_+ \otimes M_+ \otimes M_+)\). Since \(i_+^* \circ \gamma = i_+^*\), we can rewrite (9.14) as

\[(1 \otimes i_+) \circ \sigma = (i_+^* \otimes 1 \otimes 1) \circ \gamma_{12,3} \circ (\sigma \otimes \sigma).\]

(9.15)

Using the equality \(\gamma_{12,3} \circ (\sigma \otimes 1) = 1 \otimes \sigma\), we reduce (9.15) to

\[(1 \otimes i_+) \circ \sigma = (i_+^* \otimes 1 \otimes 1) \circ (1 \otimes \sigma \otimes 1) \circ \sigma.\]

(9.16)

To prove this equality, we compute the image of \(1 \in 1\) under right hand side of (9.16). In this calculation, we can ignore the action of the associator because for any representations \(V_1, V_2, V_3\) of \(g\) the associator acts trivially on the \(g\)-invariants in \(V_1 \otimes V_2 \otimes V_3\). The calculation yields that \(1\) goes to \((1 \otimes i_+(\sigma(1)))\), which proves (9.16). The claim is proved.

Let \(\mathcal{M} \subset \mathcal{M}^e\) be the full subcategory of discrete \(g\)-modules, and \(\tilde{U}_h(g) = \text{End}(\tilde{F}|_{\mathcal{M}})\) be the quantization of \(g\) constructed in Part I. It is easy to show that the homomorphism of topological Hopf algebras \(\text{End}\tilde{F} \to \tilde{U}_h(g)\) defined by restriction from \(\mathcal{M}^e\) to \(\mathcal{M}\) is an isomorphism, since both algebras are canonically isomorphic to \(U(\mathfrak{g})[[h]]\). This means that the morphism \(\chi\) defined above induces an isomorphism of topological Hopf algebras \(\tilde{U}_h(g) \to U_h(g)\). It is easy to check that this isomorphism maps \(\tilde{U}_h(g_+)\) onto \(U_h(g_+)\), which proves the proposition. \(\square\)

10. Universality and functoriality of the quantization of Lie bialgebras.
10.1. Acyclic functions.

Let $V$ be a vector space over $k$. For any integers $m, n \geq 0$, let $H_{mn} = \text{Hom}(V^\otimes m, V^\otimes n)$ be the space of tensors of rank $m, n$ on $V$.

Let $B = \bigoplus_{m,n \geq 0} H_{mn}$. We have two binary operations on $B$: the tensor product and the composition. (If the composition makes no sense, we set it to zero).

Let $m_1, ..., m_r, n_1, ..., n_r$ be nonnegative integers, and $W = \bigoplus_{i=1}^r H_{m_i, n_i}$. Let $p_i : W \to H_{m_i, n_i}$ be the natural projections.

Let $X$ be a subset of $W$ and $Y_X$ be the space of all functions from $X$ to $B$. Denote by $A_X$ the smallest subspace in $Y_X$ closed under composition and tensor product, and satisfying the following conditions:

(i) $p_i|_X \in A_X, \ i = 1, ..., r$;

(ii) If $\sigma \in Y_X$ is a permutation operator from $S_p \subset H_{pp}$, regarded as a constant function on $X$, then $\sigma \in A_X$.

We call an element of $A_X$ an acyclic function on $X$.

10.2. Universal quantization.

Let $\mathfrak{g}$ be a Lie bialgebra over $k$, and $U_h(\mathfrak{g})$ be its quantization constructed in Chapter 9. Recall that as a $k[[h]]$-module, $U_h(\mathfrak{g})$ was identified with $U(\mathfrak{g})[[h]]$, which, in turn, we identify with $S\mathfrak{g}[[h]]$ in the standard way. Therefore, the multiplication map $\mu : U_h(\mathfrak{g}) \otimes U_h(\mathfrak{g}) \to U_h(\mathfrak{g})$ splits in a direct sum of linear maps $\mu_{mn}^p : S^m \mathfrak{g} \otimes S^n \mathfrak{g} \to S^p \mathfrak{g}[[h]]$. Similarly, the coproduct $\Delta : U_h(\mathfrak{g}) \to U_h(\mathfrak{g}) \otimes U_h(\mathfrak{g})$ splits in a direct sum of linear maps $\Delta_{mn}^p : S^m \mathfrak{g} \to S^m \mathfrak{g} \otimes S^n \mathfrak{g}[[h]]$. All these linear maps are functions of the commutator $[,]$ and cocommutator $\delta$ of the Lie bialgebra $\mathfrak{g}$.

Now consider the setting of Section 10.1, with $m_1 = 2, m_2 = 1, n_1 = 1, n_2 = 2, W = \text{Hom}(V \otimes V, V) \oplus \text{Hom}(V, V \otimes V), X \subset W$ the set of all pairs $([,]$, $\delta) \in W$ satisfying the axioms of a Lie bialgebra. To every Lie bialgebra $\mathfrak{g} \in X$ ($\mathfrak{g} = (V, [\cdot, \cdot], \delta)$), we have associated a quantized universal enveloping algebra $U_h(\mathfrak{g})$, which is identified with $SV[[h]]$ as a $k[[h]]$-module. Thus, we can regard $\mu_{mn}^p, \Delta_{mn}^p$ as functions on $X$ with values in $H_{m+n,p}[[h]], H_{p,m+n}[[h]]$, respectively.

**Theorem 10.1.** The coefficients of the $h$-expansion of $\mu_{mn}^p, \Delta_{mn}^p$, are acyclic functions on $X$.

**Remark.** Drinfeld calls a quantization having this property a universal quantization. Thus, the quantization of Lie bialgebras constructed in Chapter 9 is universal.

Theorem 10.1 implies functoriality of quantization. Namely, let $\text{LBA}$ denote the category of Lie bialgebras over $k$, and $\text{QUEA}$ denote the category of quantum universal enveloping algebras over $k[[h]]$.

**Theorem 10.2.** There exists a functor $Q : \text{LBA} \to \text{QUEA}$ such that for any $\mathfrak{g} \in \text{LBA}$ we have $Q(\mathfrak{g}) = U_h(\mathfrak{g})$.

**Proof.** On objects, the functor $Q$ is already defined. Now let us define it on morphisms. Let $f : \mathfrak{g}_1 \to \mathfrak{g}_2$ be a homomorphism of Lie bialgebras. It defines a linear map $Q(f) : S\mathfrak{g}_1[[h]] \to S\mathfrak{g}_2[[h]]$. By Theorem 10.1, this map defines a homomorphism of Hopf algebras $U_h(\mathfrak{g}_1) \to U_h(\mathfrak{g}_2)$. The theorem is proved. □.

10.3. **Proof of Theorem 10.1.** Let $\mathfrak{g}_+^+$ be a Lie bialgebra, $U_h(\mathfrak{g}_+^+)$ be its quantization. We will use the notation of Section 9.
By the definition, $U_h(\mathfrak{g}_+) = F(M_-) = \text{Hom}(M_-, M^+_1 \otimes M_-)$. We have the identifications $\xi_\pm: S\mathfrak{g}_+ \rightarrow M_\pm$ given by
\[(10.1) \quad \xi_\pm(\text{Sym}(x_1 \otimes \ldots \otimes x_l)) = \text{Sym}(x_1 \ldots x_l)1_\pm, x_i \in \mathfrak{g}_+,
\]
and $\theta : U_h(\mathfrak{g}_+) \rightarrow M_-[[h]]$ by
\[
\theta(x) = (1_+ \otimes 1)(x1_-).
\]
They give us identifications $\eta = \theta^{-1} \xi_-$ : $S\mathfrak{g}_+[[h]] \rightarrow U_h(\mathfrak{g}_+)$, and $\xi^+_\pm : M^*_\pm \rightarrow \hat{S}\mathfrak{g}_+$ (here hat denotes the completion by degree). From now on we fixed these identifications and thus regard the spaces $S^g, M^*_\pm, U_h(\mathfrak{g}_+)$ as sums of spaces of the form $S^m_\mathfrak{g}_+$ or $S^m\mathfrak{g}_+[[h]]$. This allows us to make sense of the statement that certain maps between tensor products of these spaces, depending on $[\cdot, \cdot], \delta$, are acyclic functions on $X$.

To prove the theorem, we need to show that the maps $\mu$, $\Delta$, $S$ are acyclic.

To implement the proof, we need a few Lemmas.

**Lemma 10.3.** (i) The map $r: M_- \otimes M_- \rightarrow M_- \otimes M_-$ is acyclic.

(ii) The maps $r, r^{op}: M^*_+ \otimes M_- \rightarrow M^*_+ \otimes M_-$ are acyclic.

**Proof.** (i) For any nonnegative integers $m, n$ consider the mapping $\mathfrak{g}^+_m \otimes \mathfrak{g}^+_n \rightarrow S\mathfrak{g}_+ \otimes S\mathfrak{g}_+$, given by
\[(10.2) \quad x_1 \otimes \ldots \otimes x_m \otimes y_1 \otimes \ldots \otimes y_n \rightarrow r(x_1 \ldots x_n 1_- \otimes y_1 \ldots y_m 1_-).
\]

We need to show that this mapping is an acyclic function. We can do this by induction in $N = m + n$. If $N = 0$, the operator is zero and the statement is clear. Assume the statement is proved for $N = K - 1$ and let us prove it for $N = K$. Using the relation $[x \otimes 1 + 1 \otimes x, r] = \delta(x), x \in \mathfrak{g}_+$, we can reduce the question to the case $m = K, n = 0$. In this case, the map is again zero, Q.E.D.

(ii) By the same reasoning as in (i), we get the statement for $r$. For $r^{op}$, we reduce the question to proving that the map $M^*_+ \rightarrow M^*_+ \otimes M_-$ given by $v \mapsto r^{op}(v \otimes 1_-)$ is acyclic.

Let $u = \text{Sym}(y_1 \ldots y_m)1_+ \in M_+, y_1, \ldots, y_m \in \mathfrak{g}_-$. Let us compute the expression
\[
X = (u \otimes 1)(r^{op}(v \otimes 1_-)) \in M_-.
\]
We get
\[(10.3) \quad X = -(r^{op}(u \otimes 1))(v \otimes 1_-) = \sum_i \langle L(b^i, y_1, \ldots, y_m)1_+, v \rangle a_i 1_-,
\]
where $a_i, b^i$ are dual bases of $\mathfrak{g}_+, \mathfrak{g}_-$, and $L$ is a polynomial of commutators of $b^i, y_1, \ldots, y_m$ over $\mathbb{Q}$ which is symmetric in $b_i, y_1, \ldots, y_m$ and depends only on $m$.

Using the duality of $\mathfrak{g}_+$ and $\mathfrak{g}_-$, from (10.3) we get
\[(10.4) \quad X = \sum_i \langle b^i \otimes y_1 \otimes \ldots \otimes y_m, D_L(v) \rangle a_i 1_-
\]
where $D_L(v) \in S\mathfrak{g}_+$ is a linear combination of iterated cocommutators applied to $v$. This implies that $r^{op}(v \otimes 1_-)$ is a linear combination of iterated cocommutators applied to $v$, so the map $v \mapsto r^{op}(v \otimes 1_-)$ is acyclic. □

For any $x \in M_-$, let $\psi_x : M_- \rightarrow M^*_+ \otimes M_-$ be the morphism such that $(1_+ \otimes 1)(\psi_x 1_-) = x$. 36
Lemma 10.4. The map \( M_+ \otimes M_+ \rightarrow M_+^\# \otimes M_- \) defined by \( x \otimes y \rightarrow \psi_x y \) is acyclic.

Proof. For any \( x \in M_+ \), \( y \in U(\mathfrak{g}_+) \) we have \( \psi_x y \in_- = \Delta_0(y) \psi_x 1_- \), where \( \Delta_0 \) is the coproduct in \( U(\mathfrak{g}_+) \). Since the map \( \Delta_0 \) is obviously acyclic, it suffices to show that the assignment \( x \rightarrow \psi_x 1_- \) is an acyclic map \( M_+ \rightarrow M_+^\# \otimes M_- \).

Let \( z \in U(\mathfrak{g}_-) \). Since the vector \( \psi_x 1_- \) is \( \mathfrak{g}_- \)-invariant, we have
\[
(z_1 \otimes 1)(\psi_x 1_-) = (1 \otimes S_0(z))(\psi_x 1_-) = S_0(z)x,
\]
where \( S_0 \) is the antipode of \( U(\mathfrak{g}_-) \). Let \( z = \text{Sym}(z_1 \otimes \cdots \otimes z_m) \), \( x = \text{Sym}(x_1 \otimes \cdots \otimes x_n) 1_- \), \( z_i \in \mathfrak{g}_- \), \( x_i \in \mathfrak{g}_+ \). Computing the product \( S_0(z)x \), we see that it is a linear combination of products of expressions of the form \( x_i \) and \( Z = [\text{ad}^* x_i, \cdots \text{ad}^* x_i, z_j, x_i] \), applied to \( 1_- \), where \([za]_+ \) denotes the \( \mathfrak{g}_+ \)-component of \([za] \). Using the identity \([za]_+ = (1 \otimes z, \delta(a))\), we can rewrite \( Z \) in the form \( Z = \pm (1 \otimes z_j, (\text{ad} x_i \otimes 1) \delta(x_i)) \). This shows that the product \( S_0(z)x \), regarded as an element of \( S\mathfrak{g}_+ \), can be represented as a linear combination of summands of the form
\[
\langle z_1 \otimes \cdots \otimes z_m \otimes 1^s, x' \rangle,
\]
where \( x' \in S\mathfrak{g}_+ \) is a polylinear symmetric function of \( x_1, \ldots, x_n \), such that the assignment \( \text{Sym}(x_1 \otimes \cdots \otimes x_n) \rightarrow x' \) is acyclic. This proves the acyclicity of \( \psi_x 1_- \).

Now we can show the acyclicity of the product in \( U_h(\mathfrak{g}_+) \). According to Chapter 9, for any \( x, y \in M_+ \),
\[
(1_+ \otimes 1_+ \otimes 1)(\Phi^{-1}(1 \otimes \psi_y)\psi_x 1_-)
\]
Since \( \Phi^{-1} \) is a noncommutative formal series of \( h\Omega_{12}, h\Omega_{23} \), the acyclicity of the map \( x \otimes y \rightarrow x * y \) follows from Lemmas 10.3 and 10.4.

To prove the acyclicity of the coproduct \( \Delta \), consider the linear operator \( \mathcal{J} \in \text{End}_k(M_+ \otimes M_-)[[h]] \) defined by
\[
\mathcal{J}(x \otimes y) = (1_+ \otimes 1_+ \otimes 1)(\Phi^{-1}_{1_1,2_1,3_1} \Phi_{2,3,4}^{-1} \gamma_{1,2_3,4} \Phi_{2,3,4}^{-1}(\psi_x 1_- \otimes \psi_y 1_-)).
\]

According to Proposition 9.3, the coproduct on \( U_h(\mathfrak{g}_+) \), (when \( U_h(\mathfrak{g}_+) \) is identified with \( M_+ \)), is written in the form
\[
\Delta(x) = \mathcal{J}^{-1}i_-(x).
\]
The map \( J \) is acyclic by Lemmas 10.3 and 10.4. Therefore, \( \Delta \) is acyclic.

10.4. Universal quantization of quasitriangular Lie bialgebras.

Let \( \mathfrak{g} \) be a quasitriangular Lie bialgebra over \( k \), and \( U^q(\mathfrak{g}) \) be its quasitriangular quantization constructed in Chapter 6. As a \( k[[h]] \)-module, \( U^q(\mathfrak{g}) \) was identified with \( U(\mathfrak{g})[[h]] \), which we identify with \( S\mathfrak{g}[[h]] \) in the standard way. Therefore, the multiplication map \( \mu : U^q(\mathfrak{g}) \otimes U^q(\mathfrak{g}) \rightarrow U^q(\mathfrak{g}) \) splits in a direct sum of linear maps \( \mu_{mn}^p : S^m \mathfrak{g} \otimes S^n \mathfrak{g} \rightarrow S^p \mathfrak{g}[[h]] \). Similarly, the coproduct \( \Delta : U^q(\mathfrak{g}) \rightarrow U^q(\mathfrak{g}) \otimes U^q(\mathfrak{g}) \) splits in a direct sum of linear maps \( \Delta_{mn}^p : S^m \mathfrak{g} \rightarrow S^m \mathfrak{g} \otimes S^n \mathfrak{g}[[h]] \), and the quantum \( R \)-matrix \( R \) splits in a direct sum of \( R_{mn} \in S^m \mathfrak{g} \otimes S^n \mathfrak{g}[[h]] \). All these linear maps are functions of the commutator \([,] \) and the classical \( r \)-matrix \( r \) of \( \mathfrak{g} \).
Now consider the setting of Section 10.1, with $m_1 = 2, m_2 = 0, n_1 = 1, n_2 = 2$, $W = \text{Hom}(V \otimes V, V) \oplus V \otimes V$, $X \subset W$ the set of all pairs $([\cdot, \cdot], r) \in W$ satisfying the axioms of a quasitriangular Lie bialgebra. To every quasitriangular Lie bialgebra $g \in X$ ($g = (V, [\cdot, \cdot], r)$), we have associated a quantized universal enveloping algebra $U_h^{qt}(g)$, which is identified with $SV[[h]]$ as a $k[[h]]$-module. Thus, we can regard $\mu_{mn}^p, \Delta_{mn}^p, R_{mn}$ as functions on $X$ with values in $H_{m+n,p}[[h]], H_{p,m+n}[[h]], H_{0,m+n}[[h]]$, respectively.

**Theorem 10.5.** The coefficients of the $h$-expansion of $\mu_{mn}^p, \Delta_{mn}^p, R_{mn}$ are acyclic functions on $X$.

*Proof.* The proof is analogous to the proof of Theorem 10.1. □

Theorem 10.5 implies functoriality of quasitriangular quantization. Namely, let $\text{QTLBA}$ denote the category of quasitriangular Lie bialgebras over $k$, and $\text{QTQUEA}$ denote the category of quasitriangular quantum universal enveloping algebras.

**Theorem 10.6.** There exists a functor $Q^{qt} : \text{QTLBA} \to \text{QTQUEA}$ such that for any $g \in \text{QTLBA}$ we have $Q^{qt}(g) = U_h^{qt}(g)$.

*Proof.* The proof is analogous to the proof of Theorem 10.2. □

10.5. Universal quantization of classical $r$-matrices.

Let $A$ be an associative algebra over $k$ with unit, and $r \in A \otimes A$ be a solution of the classical Yang-Baxter equation. In Chapter 5, we assigned to $(A, r)$ a solution of the quantum Yang-Baxter equation $R(r) \in A \otimes A[[h]]$.

Consider the setting of Section 10.1, with $m_1 = 2, m_2 = 0, m_3 = 0, n_1 = 1, n_2 = 1, n_3 = 2, W = \text{Hom}(V \otimes V, V) \oplus V \otimes V \otimes V, X \subset W$ the set of all triples $(*, 1, r) \in W$ such that $*$ is an associative product, $1$ is a unit, and $r$ satisfies the classical Yang-Baxter equation. To every $A \in X$ ($A = (V, *, 1, r)$), we have associated a quantum $R$-matrix $R(r) \in A \otimes A[[h]]$. Thus, we can regard $R$ as a function on $X$ with values in $H_{02}[[h]]$.

**Theorem 10.7.** The coefficients of the $h$-expansion of $R$ are acyclic functions on $X$.

*Proof.* The theorem follows from Theorem 10.5. □

Theorem 10.5 implies functoriality of quantization of classical $r$-matrices.

Namely, let us call a classical Yang-Baxter algebra a pair $(A, r)$, where $A$ is an associative algebra with unit over $k$, and $r \in A \otimes A$ satisfies the classical Yang-Baxter equation, and a quantum Yang-Baxter algebra a pair $(A, R)$, where $A$ is an associative algebra with unit over $k$, and $R \in A \otimes A[[h]]$ satisfies the quantum Yang-Baxter equation. Let $\text{CYBA, QYBA}$ denote the categories of classical, respectively quantum, Yang-Baxter algebras. Morphisms in these categories are algebra homomorphisms preserving the unit and $r$ (respectively, $R$).

**Theorem 10.8.** There exists a functor $Q^{YB} : \text{CYBA} \to \text{QYBA}$ such that for any $(A, r) \in \text{CYBA}$ we have $Q^{YB}(A, r) = (A, R(r))$.

*Proof.* The proof is analogous to the proof of Theorem 10.2. □
Let $K$ be a local Artinian or pro-Artinian commutative algebra over $\mathbb{Q}$, and $I$ be the maximal ideal in $K$. Let $k = K/I$ (it is a field of characteristic 0). Let $LBA(K)$, $QTLBA(K)$, $QUEA(K)$, $QTQUEA(K)$ be the categories of Lie bialgebras, quasitriangular Lie bialgebras, quantum universal enveloping algebras, quasitriangular quantum universal enveloping algebras over $K$ which are topologically free as $K$-modules and cocommutative modulo $I$. Let $CYBA(K)$, $QYBA(K)$ be the categories of classical Yang-Baxter algebras, quantum Yang-Baxter algebras, which are topologically free as $K$-modules and trivial modulo $I$ (i.e. $r = 0, R = 1$ modulo $I$).

In Section 10.2, we showed that $\mu, \delta$ are series of acyclic functions of $[.,.]$, $h\delta$ with rational coefficients. Similarly, in Section 10.4, we showed that $\mu, \Delta, R$ are series of acyclic functions with rational coefficients of $[.,h\delta]$, and in Section 10.5 that $R$ is a series of acyclic functions with rational coefficients of $[[.,1]]$. Therefore, we can use these formulas to define quantization over $K$ (the series will converge in the topology of $K$). This quantization over $K$ possesses the same functorial properties as the original quantization over $k[[h]]$. Thus, we obtain quantization functors $Q_A : LBA(K) \to QUEA(K)$, $Q_{Kq} : QTLBA(K) \to QTQUEA(K)$, $Q_{KB} : CYBA(K) \to QYBA(K)$.

**Appendix: computation of the product in $U_h(a)$ modulo $h^3$.**

To illustrate the proof of Theorem 10.1, here we compute the product in the quantization $U_h(a)$ of a Lie bialgebra $a$ modulo $h^3$. In the text below we always assume summation over repeated indices.

Let $\{a_i, i \in I\}$ be a basis of $a$, and $\{b^i\}$ be the topological basis of $a^*$ dual to $\{a_i\}$. Let us write down the commutation relations for the Lie algebra $g = a \oplus a^*$:

\[
(a_1)
\]

\[
[a_i, a_j] = c_{ij}^k a_k, \quad [b^i b^j] = f^{ij}_k b^k, \quad [a_i b^j] = f^{jk}_i a_k - c^{ij}_k b^k.
\]

Let $1^*_x \in M^*_x$ be the functional on $M^*_x$ defined by $1^*_x(x 1^*_+) = \varepsilon(x)$, $x \in U(a)$. Let $\{(M^*_x)_n\}$ be the filtration of $M^*_x$ which was defined in Chapter 7.

For $x \in U(a)$, let $\psi_x : M_- \to M^*_+ \widehat{\otimes} M_-$ be the $g$-intertwiner such that

\[
\psi_x 1_- \equiv 1^*_x \otimes x 1_- \mod (M^*_x)_1.
\]

For $x, y \in U(a)$, we defined the quantized product $z = y \circ x$ to be the element of $U(a)[[h]]$ such that the operator $\psi_z$ is the composition

\[
\begin{align*}
M_- &\xrightarrow{\psi_z} M^*_+ \widehat{\otimes} M_- \xrightarrow{1 \otimes \psi_y} M^*_+ \widehat{\otimes} (M^*_+ \widehat{\otimes} M_-) \xrightarrow{\Phi^{-1}} \\
\left(M^*_+ \widehat{\otimes} M^*_+\right) \widehat{\otimes} M_- &\xrightarrow{1 \otimes 1} M^*_+ \widehat{\otimes} M_-
\end{align*}
\]

(A2)

We want to compute the product $a_q \circ a_p$ modulo $h^3$. We fix elements $\rho_i \in M^*_+$, $i \in I$, such that $\rho_i(1^*_+) = 0$, $\rho_i(b^i 1^*_+) = \delta^i_1$. These elements are uniquely defined modulo $(M^*_+)_2$.

Let $w^i \in M_-$ be the vectors such that

\[
\psi_{ap} 1_- \equiv 1^*_+ \otimes a_p 1_- + \rho_i \otimes w^i \mod (M^*_+)_2 \otimes M_-.
\]

(A3)

We must have $b^j \psi_{ap} 1_- = 0$ for all $j$, so $1^*_+ \otimes b^j a_p 1_- + b^j \rho_i \otimes w^i = 0$. But $b^j \rho_i(1^*_+) = \rho_i(-b^j 1^*_+) = -\delta^i_j$, so we get $w^i = b^i a_p 1_- = -f^{ik}_j a_k 1_-$. 39
Thus we get
\[ \psi_{a_p} 1_- \equiv 1^*_+ \otimes a_p 1_- - f^{ik}_p \rho_i \otimes a_k 1_- \mod (M^*_+)_2 \hat{\otimes} M_. \]

Using (A4), we get
\[ \psi_{a_q} a_r 1_- \equiv (a_r \otimes 1 + 1 \otimes a_r) \psi_{a_q} 1_- \equiv \]
\[ 1^*_+ \otimes a_r a_q 1_- - f^{ik}_q a_r \rho_i \otimes a_k 1_- - f^{ik}_q \rho_i \otimes a_r a_k 1_- \mod (M^*_+)_2 \hat{\otimes} M_. \]

We have
\[ a_r \rho_i (b^j 1_+) = -\rho_i (a_r b^j 1_+) = \rho_i (c^{ij}_r b^k 1_+) = c^{ij}_r, \]
Thus, substituting (A6) into (A5), we get
\[ \psi_{a_q} a_r 1_- \equiv 1^*_+ \otimes a_r a_q 1_- - f^{ik}_q c^{ij}_r \rho_j \otimes a_k 1_- - f^{ik}_q \rho_i \otimes a_r a_k 1_- \mod (M^*_+)_2 \hat{\otimes} M_. \]

In particular, we have
\[ (1 \otimes \psi_{a_q}) \psi_{a_p} 1_- \equiv 1^*_+ \otimes 1^*_+ \otimes a_q a_p 1_- - c^{ij}_p f^{ik}_q 1^*_+ \otimes \rho_j \otimes a_k 1_- - f^{ik}_q 1^*_+ \otimes \rho_i \otimes a_p a_k 1_- - f^{ik}_q \rho_i \otimes 1^*_+ \otimes a_k a_q 1_- + f^{ik}_q c^{ij}_k f^{ls}_q \rho_i \otimes \rho_j \otimes a_s 1_- + f^{ik}_q f^{ls}_q \rho_i \otimes \rho_l \otimes a_k a_s 1_- \mod (M^*_+)_2 \hat{\otimes} M_+ \hat{\otimes} (M^*_+)_2 \hat{\otimes} M_. \]

The definition of an associator implies
\[ \Phi = 1 + \frac{h^2}{24} [t_{12}, t_{23}] + O(h^3). \]
(see [Dr2],[Dr4]). This means that the part of the \( h^2 \)-coefficient of \( \Phi^{-1} \) \( V_1 V_2 V_3 \) which belongs to \( a^* \otimes a^* \otimes a \) is \( \frac{1}{24} c^{ij}_k b^i \otimes b^j \otimes a_k \).

Now let us apply \( \Phi^{-1} \) to both sides of (A8). We want to compute the answer in the form \( 1^*_+ \otimes 1^*_+ \otimes u + \ldots, u \in M_-[\hat{h}] \). To do this, we only need to use the last two terms on the r.h.s. of (A8) and the \( a^* \otimes a^* \otimes a \)-part of the quadratic term of \( \Phi \). The calculation gives
\[ \Phi^{-1} (1 \otimes \psi_{a_q}) \psi_{a_p} 1_- \equiv 1^*_+ \otimes 1^*_+ \otimes u \mod (M^*_+)_1 \hat{\otimes} M^*_+ \hat{\otimes} M_- + M^*_+ \hat{\otimes} (M^*_+)_1 \hat{\otimes} M_. \]
\[ u = a_q a_p 1_- + \frac{h^2}{24} (f^{ik}_p f^{ls}_q c^{ij}_k c^{m}_{ij} a_m a_s + f^{in}_p f^{ls}_q c^{ij}_i a_r a_n a_s) 1_- \]

This shows that
\[ a_q \circ a_p = a_q a_p + \frac{h^2}{24} (f^{ik}_p f^{ls}_q c^{ij}_k c^{m}_{ij} a_m a_s + f^{in}_p f^{ls}_q c^{ij}_i a_r a_n a_s) + O(h^3). \]

This formula is analogous to the formula deduced by Drinfeld [Dr3] (equation 1.1).
It is easy to see that this formula contains only acyclic monomials. Therefore, this formula is universal.
