**ABSTRACT**

**Aims.** We investigate the X-ray spectral and timing properties of the high mass X-ray binary EXO 2030+375 observed during its June–September 2006 giant (type II) outburst.

**Methods.** The data analyzed in this work are from partly simultaneous observations with **INTEGRAL** and **Swift**. The pulse period \(P\) and its temporal derivative \(\dot{P}\) are measured. X-ray pulse profiles in different energy ranges and time intervals are constructed. Pulse averaged X-ray spectra for different time intervals are studied.

**Results.** We report a strong spin-up of the source during the outburst, comparable to that observed in 1985 during the previous giant outburst when the source was discovered. The value of \(P\) is found to be linearly related to the X-ray luminosity of the source during the outburst. For the first time the hard X-ray (> 25 keV) characteristics of the source during a type II outburst are studied. The X-ray pulse profiles apparently change with luminosity. The X-ray spectral continuum in the 3–120 keV energy range is modeled with an absorbed power law with an exponential cutoff around \(E \sim 26\) keV. An iron emission line at \(\sim 6–7\) keV is observed. The spectrum reveals some features between 10 and 20 keV which can be modeled either by a broad emission line at \(\sim 13–15\) keV (a “bump”) or by two absorption lines at \(\sim 10\) and \(\sim 20\) keV.

**Key words.** X-ray binaries; neutron stars; accretion disks

**1. Introduction**

Discovered by **EXOSAT** in 1985 during a giant outburst (Parmar et al. 1989), the transient accreting pulsar EXO 2030+375 belongs to a high mass X-ray binary system with a B0 Ve star as optical companion (Parmar et al. 1989). The orbital period and eccentricity are \(\sim 46.6\) and \(\sim 0.42\), respectively (Wilson et al. 2005). According to the generally accepted model for Be/X-ray binaries, the X-ray emission in such systems during outbursts is produced when the compact object accretes from a quasi-Keplerian disk around the equator of the rapidly rotating Be star. Such a mechanism explains normal (type I) outbursts with X-ray luminosity \(L_X \leq 10^{37}\) erg s\(^{-1}\), associated with the periastron passage of the compact object (Coe 2000).

\* Based on observations with **INTEGRAL**, an ESA project with instruments and science data centre funded by ESA member states (especially the PI countries: Denmark, France, Germany, Italy, Switzerland, Spain), Czech Republic and Poland, and with the participation of Russia and the USA.

**Table 1. Summary of observations.**

| Obs. | Instrument | Obs.time | Mean MJD | Mean ASM flux (mCrab) |
|------|------------|----------|-----------|----------------------|
| OBS1 | ISGRI+JEM-X | 62       | 53942.9   | 500                  |
| OBS2 | ISGRI+JEM-X | 140      | 53967.6   | 500                  |
| OBS3 | XRT + BAT  | 6.3      | 53967.3   | 500                  |
| OBS3 | XRT + BAT  | 6.4      | 54002.5   | 160                  |

During the 1985 giant outburst the X-ray luminosity of the source reached a value of \(L_{1-20\text{ keV}} \sim 2 \times 10^{38}\) erg s\(^{-1}\) (for a distance of 7.1 kpc, Wilson et al. 2002). The spin period of the pulsar \(\sim 42\) s changed dramatically, with a spin-up time scale \(-\dot{P}/P \approx 30\) yr (Parmar et al. 1989).

From the nearly continuous monitoring of the source with the Burst and Transient Source Experiment (BATSE) on the Compton Gamma Ray Observatory (CGRO) and the All Sky Monitor (ASM) on the Rossi X-ray Timing Explorer (RXTE) it is known that the pulse period remained roughly constant for about a year after the beginning of the monitoring in 1991, followed by 2 years of relatively slow spin-up and 6 years of slow spin-down (Wilson et al. 2002, 2005). After 2002 a transition to a global spin-up along with an overall brightening of the normal outbursts was reported by Wilson et al. (2005).
The giant outburst of EXO 2030+375 presented here (Corbet & Levin 2006; Krimm et al. 2006; McCollough et al. 2006) is the second of its kind since the discovery of the source. The X-ray luminosity at the maximum of the outburst reached $L_{1-10\text{keV}} \sim 1.2 \times 10^{38}\text{erg}\text{s}^{-1}$ (Wilson & Finger 2006). In this Letter, based on INTEGRAL and Swift data, we investigate in § 2.1 the pulse period and the spin-up rate of the source and in § 2.2 we construct X-ray pulse profiles for different energy ranges and time intervals. To characterize the broad-band spectral behaviour we perform in § 2.3 the spectral analysis of pulse-phase averaged spectra of the source. A detailed study of the timing and spectral behaviour as a function of the luminosity is beyond the scope of this Letter and will be presented in a forthcoming paper.

2. Observations and data analysis

EXO 2030+375 was observed by INTEGRAL (Winkler et al. 2003) on 27 July and 19–21 August 2006 and by Swift (Gehrels et al. 2004) on 19–20 August and 23–25 September 2006. Another simultaneous observation by INTEGRAL and Swift was performed on 6–8 October 2006, but the data were not available at the time of writing this Letter and will be presented later. For our analysis we used the data obtained with the instruments IBIS/ISGRI (20–300 keV, Ubertini et al. 2003) and JEM-X (3–30 keV, Lund et al. 2003) onboard INTEGRAL as well as XRT (0.2–10 keV, Burrows et al. 2005) and BAT (15–150 keV, Barthelmy et al. 2005) of Swift. For the analysis of ISGRI and JEM-X data the Off-line Science Analysis (OSA) software (version 5.1) was used (Courvoisier et al. 2003). Analysis of XRT data was done with the standard HEADAS package (version 6.0.4).

Table 1 contains the summary of the observations analyzed in this work. A part of the ASM light curve of the source including three normal outbursts and the 2006 giant outburst is presented in Figure 1. The observations analyzed in this paper are marked by solid lines and consist of three sets of pointings. The first set was done by INTEGRAL. The second set contains simultaneous observations by Swift and INTEGRAL. The last set of observations was performed by Swift. These three sets will be referred to as OBS1, OBS2, and OBS3 throughout the paper. OBS1 and OBS2 observations were made when the source was at approximately the same luminosity level, before and after the maximum of the outburst. OBS3 set was made during the decay of the outburst when the luminosity of the source dropped by a factor of $\sim 3$.

### 2.1. Pulse period behaviour

For the timing analysis all times were translated to the solar system barycenter and corrected for orbital motion in the binary. The pulse periods and associated derivatives were determined for each of the three observation periods individually (Table 2). These values were found by employing initial epoch-folding and a subsequent phase connection analysis similar to Ferrigno et al. (2006) using well defined pulse profiles from a sufficiently large number of pulses. Variation in pulse shape inside each observation is marginal and does not affect our method.

Fig. 2 displays our points together with the historical pulse period development as presented by Wilson et al. (2002, 2005). The large triangles correspond to our pulse frequency measurements during the outburst. The uncertainties of measurements and duration of each observation are smaller than the size of symbols in the plot.

### Table 2. Pulse period development

| Obs. | MJD   | $P$   | $\dot{P}$ | Flux (3–10 keV) |
|------|-------|-------|-----------|----------------|
|      | [s]   | $\times 10^{-8}\text{s}\text{s}^{-1}$ | [erg cm$^{-2}\text{s}^{-1}$] | |
| OBS1 | 53942.7714 | 41.57958(2) | 2.93(12) | 9.61(6) |
| OBS2 | 53967.4260 | 41.51706(3) | 3.29(19) | 10.41(4) |
| OBS3 | 54002.3877 | 41.45954(4) | 0.67(10) | 3.25(3) |

are referred to as OBS1, OBS2, and OBS3 throughout the paper. OBS1 and OBS2 observations were made when the source was at approximately the same luminosity level, before and after the maximum of the outburst. OBS3 set was made during the decay of the outburst when the luminosity of the source dropped by a factor of $\sim 3$.

Fig. 2. Spin frequency of EXO 2030+375. Small diamonds show the spin frequency development before the 2006 giant outburst (they are taken from Wilson et al. 2002, 2005). The large triangles correspond to our pulse frequency measurements during the outburst. The uncertainties of measurements and duration of each observation are smaller than the size of symbols in the plot.

---

1 We used the results provided by the ASM/RXTE teams at MIT and at the RXTE SOF and GOF at NASA’s GSFC.
digit(s). The characteristic spin-up time scale, \(-P/\dot{P}\), is \(\sim 40\) years, somewhat longer than during the first giant outburst. We also note that the \(P\) appears to be linearly correlated with the X-ray luminosity (see last two columns in Table 2). The formal correlation coefficient is 1.0 and the slope from a linear fit is \(36 \pm 2\) (s s\(^{-1}\))/erg cm\(^{-2}\)s\(^{-1}\), although it is based on three data points.

### 2.2. Pulse profiles

Using the values of \(P\) and \(\dot{P}\) determined here (Table 2) we constructed pulse profiles for each observation. Pulse profiles from OBS1 and OBS2 are found to be very similar. This can be expected considering that the luminosity of the source during these observations was approximately the same. The results are shown in Figs. 3 and 4. We do not show pulse profiles from OBS1 since there are similar to OBS2.

Fig. 4 shows the 0.2–10 keV pulse profiles obtained with XRT. One can see that the pulse profile obtained in OBS3, during the decay of the outburst, appears different from that obtained in OBS2 when the luminosity was higher.

The analysis of the pulse profiles, including the comparison with those obtained during the 1985 outburst and during normal outbursts, is on-going.

### 2.3. Spectral analysis

For OBS1 pulse averaged X-ray spectra of ISGRI and JEM-X were analyzed. For OBS2 spectra from ISGRI, JEM-X, XRT and BAT were fitted simultaneously. In order to account for small scale uncertainties in the response matrices of the respective instruments systematic uncertainties were added at a level of 1\% for ISGRI and 3\% for JEM-X and XRT. For BAT we used energy-dependent systematic errors provided by the HEADAS package. We note that there are additional global systematic uncertainties with the instruments on INTEGRAL (e.g. the canonical spectrum of the Crab is not reproduced). The stated uncertainties (e. g. in Tables 3 and 4) are therefore to be taken as lower limits.

To fit the broad band continuum of the source we used an absorbed power law with an exponential cutoff (XSPEC highecut model):

\[\frac{dN}{dE} \propto \begin{cases} E^{-\Gamma}, & \text{if } E \leq E_{\text{cutoff}}, \\ E^{-\Gamma} \cdot \exp \frac{E - E_{\text{fold}}}{E_{\text{cutoff}}}, & \text{if } E > E_{\text{cutoff}}, \end{cases}\]

where \(dN/dE\) is the differential count rate, \(E\) is the energy of the photons; \(\Gamma\), \(E_{\text{cutoff}}\), and \(E_{\text{fold}}\) are model parameters. An iron emission line at \(\sim 6.5\) keV was observed during OBS2 (which has the largest total number of counts) and modeled by a Gaussian emission line. JEM-X data revealed an additional feature in 10–20 keV range, which could be explained by a Gaussian emission model at \(-13–15\) keV (a “bump”). Alternatively, following the suggestion of a cyclotron line at \(\sim 10\) keV by Wilson & Finger (2006), we equally well fitted the spectra adding two Gaussian absorption lines at \(\sim 10\) and \(\sim 20\) keV to the broad band continuum. To account for large systematic uncertainties in the absolute flux measured by the instruments we introduced in our models a free multiplicative factor for each instrument: \(F_{\text{ISGRI}}\), \(F_{\text{XRT}}\), and \(F_{\text{BAT}}\) (for JEM-X the factor was fixed to 1.0). The best fit spectral parameters for OBS1 and OBS2 are listed in Table 3 (for the model with a “bump”) and Table 4 (for the model with two absorption lines). The broad band spectrum of OBS2 fitted with the highecut model is shown in Fig. 5a. Figures 5b, 5c and 5d show the highcut absorption lines. The broad band spectrum of OBS2 fitted with the model with a “bump” around 15 keV, and, alternatively, with two Gaussian absorption lines.

### 3. Summary and Discussion

In June–September 2006 EXO 2030+375 has undergone the second giant (type II) outburst since its discovery in 1985. During the outburst the source has been observed with INTEGRAL and Swift. The main results of these observations can be summarized as follows:

1. The spin frequency of the pulsar has dramatically increased, indicating the presence of an accretion disk around the neutron star. The maximum value of \(\dot{P}\) is found to be comparable to that observed during the first outburst during which the source was discovered. The values of \(\dot{P}\) determined for the three

| Time of observation (MJD) | ISGRI, JEM-X | ISGRI, JEM-X |
|--------------------------|--------------|--------------|
| 1993| 53943(OBS1) | 53967(OBS2) |
| 53943(OBS1) | ISGRI, JEM-X | ISGRI, JEM-X |
| 53967(OBS2) | ISGRI, JEM-X | ISGRI, JEM-X |
| 1.00 ± 0.01 | 1.93 ± 0.01 |
| 26.4 ± 0.5 | 25.9 ± 0.3 |

| 1.0 ± 01 | 1.20 ± 01 |
| 0.926 ± 0.004 | 0.926 ± 0.004 |
| 0.91 ± 0.01 | 0.91 ± 0.01 |
| 1.1/259 | 1.3/397 |
observation periods are linearly related to the X-ray luminosity, in line with previous observations (Parmar et al. 1989) and the prediction of accretion torque theory (Ghosh & Lamb 1979).

Since the luminosity of the source and its spin-up rate could be measured, we can estimate the value of the magnetic field strength using the relation $L = \mu^2 / (2M \sqrt{GMR_A})$, where $L$ is the moment of inertia of the neutron star, $\mu$ is the magnetic dipole moment of the neutron star, $\omega$ is the angular frequency, $R_A$ is the Alfvén radius, and $M$ is the mass of the neutron star.

Table 4. Best fit spectral parameters of EXO 2030+375 using the model with two absorption lines at ~10 ~20 keV (see text). 1σ(68%)-uncertainties for one parameter of interest are shown.
