We study the transferring of useful energy (work) along a transmission line that allows for partial preservation of quantum coherence. As a figure of merit we adopt the maximum values that ergotropy, total ergotropy, and non-equilibrium free-energy attain at the output of the line for an assigned input energy threshold. For Phase-Invariant Bosonic Gaussian Channels (BGCs) models, we show that coherent inputs are optimal. For (one-mode) not Phase-Invariant BGCs we solve the optimization problem under the extra restriction of Gaussian input signals.

**Introduction:** Quantum technologies, which are extremely successful in delivering groundbreaking improvements for information processing procedures [1], have a chance of being essential also in the management of energy sources. In particular the tremendous advances in experimental techniques witnessed in the last decade [2–7] suggest the possibility of realistically enhancing the performances of thermal machines by designing new types of devices that maintain some degree of quantum coherence in their functioning (quantum thermal machines) [8–36]. Furthermore recent studies [37–42] indicate that using genuine quantum systems as energy storing devices (quantum batteries) could be crucial in speeding up energy charging processes – see Ref. [43] for a first experimental proof-of-concept implementation. In view of these results, it makes sense to study the impact that quantum effects may have on energy transmission procedures. Here we present a first study of Quantum Energy Lines (QELs in brief) which, at variance with traditional models, are capable to preserve a certain degree of quantum coherence during the transfer of energy pulses. Previous works on the subject can be found in quantum biology, where it was observed the rather counter-intuitive feature of noise-enhanced speedup [44–46] which may actually contribute to the efficiency of the light-harvesting complexes responsible of photosynthesis [47–51]. Moreover, there have been theoretical attempts to teleport energy using ground state fluctuations of quantum fields [52, 53]. At variance with these studies, where the goal of the transmission line is to send down energy from classical energy sources to classical users, in our vision QELs could be employed to improve the connectivity between energy power plants and energy storing sites that are capable to handle energy in a quantum coherent fashion, avoiding the need to pass through unnecessary quantum-to-classical and classical-to-quantum conversion stages – see e.g. [54].

While rather unconventional, prototypical examples of QELs already exist in the form of free space or optical fiber transmission lines which are currently under development by various international agencies [55–60]. These schemes have been extensively studied by the quantum information community [61–70] and admit a formal description in terms the formalism of Bosonic Gaussian Channels (BGCs) [61–65] which we shall adopt hereafter. Within this setting, the main goal of our analysis is to identify the pulses that have to be sent through the QEL to ensure the lowest level of energy waste. Such task is not dissimilar from the optimization problem one faces with more conventional power lines: in the present case however the issue is complicated by the absence of a clear distinction between heat and work in a purely quantum mechanical setting [71–74]. Singling out the useful part (work) of the internal energy of a quantum system (in our case the output signals of the QEL), does indeed strongly depend upon the resources available to the process [75].

The maximal amount of energy one can recover by means of reversible coherent (i.e. unitary) processes [76] is the ergotropy $E$, a non-linear functional of the state of the quantum system [76]. This quantity is relevant in the study of cycles [23–28] and it has important connections with the theories of entanglement and coherence [29–31]. If we have instead access to many copies of the system, the relevant quantity is the total ergotropy $E_{\text{tot}}$, which is the work that we reversibly extract from an ensemble of asymptotically many copies of the system of interest [75, 77]. Finally, granting access to a thermal bath, we can push the work extraction process to a further level quantified by the non-equilibrium free-energy $\mathcal{F}^\beta$ of the state [78–80].

Ergotropy, total ergotropy, and non-equilibrium free-energy all qualify as bona-fide figures-of-merit for the work we can extract from a quantum system. Accordingly we shall study the efficiency of a QEL by determining which, among the set of signals that have the same input energy, ensure the highest values of $E, E_{\text{tot}}$, and $\mathcal{F}^\beta$ at the receiving end of the line. For the special case of QELs described by Phase-Insensitive (PI) BGCs which describe propagation loss, thermalization and amplification noise effects, we provide an exact solution of the optimization task showing that optical coherent states [81, 82] always ensure the best performances for all the three figures-of-merit (a result that mimics the Gaussian Optimization solution observed in the study of PI-BGC as quantum communication lines [83–86]).
the special case of general (non-PI) one-mode BGCs, obtained limiting the input signals to Gaussian states [63].

**The scheme:** We shall model a QEL as a collection of Bosonic (electromagnetic) modes that lose energy en route from the transmitter to the receiver while possibly undergoing events of amplification, and thermalization effects [62, 66, 67]. A rigorous mathematical characterization of the noise affecting the transmitted signals in these lines can be obtained in terms of Phase-Insensitive (PI) BGCs [63, 64, 87–89] whose properties we now review in brief. An n-mode Continuous Variables (CV) system is described by a complex separable Hilbert space \( \mathcal{H} \) equipped with self-adjoint bosonic field operators \( \hat{q}_1, \hat{p}_1, \ldots, \hat{q}_n, \hat{p}_n \) that obey the canonical commutation relations (i.e. \( [\hat{q}_j, \hat{q}_k] = [\hat{p}_j, \hat{p}_k] = 0, [\hat{q}_j, \hat{p}_k] = i\delta_{jk} \mathbb{I} \) with \( \mathbb{I} \) the identity operator), and by the free electromagnetic Hamiltonian \( \hat{H} := \sum_{j=1}^n \frac{\hat{q}_j^2 + \hat{p}_j^2}{2} - \frac{\hat{q}_j^2}{2} \), which we express using dimensionless units \( (\hbar = \omega = 1) \) and removing the vacuum energy contribution. The set of quantum states \( \mathcal{D}(\mathcal{H}) \) of the system comprises all positive trace-class operators on \( \mathcal{H} \) with trace 1. Introducing \( \hat{r} := (\hat{q}_1, \ldots, \hat{p}_n, \hat{q}_1, \ldots, \hat{p}_n)^T \) and using \( \{\} \) to denote the anticommutator, for each \( \hat{\rho} \in \mathcal{D}(\mathcal{H}) \) we hence define its statistical mean vector \( m(\hat{\rho}) := \text{Tr}[\hat{\rho}\hat{r}] \in \mathbb{R}^{2n} \), its covariance matrix \( \sigma(\hat{\rho}) \in \mathbb{R}^{2n \times 2n} \) of elements \( \sigma_{jk}(\hat{\rho}) := \text{Tr}[\hat{\rho}\{\hat{r}_j, \hat{r}_k\} - m_j m_k] \), and its characteristic function \( \chi(\hat{\rho}; x) := \text{Tr}[\hat{\rho}\hat{D}(x)] \), where \( \hat{D}(x) := \exp[i\hat{r} \cdot x] \) is the Weyl or displacement operator and \( x \in \mathbb{R}^{2n} \). We also say that \( \hat{\rho} \in \mathcal{D}(\mathcal{H}) \) is a Gaussian state when the associate characteristic function is gaussian \([88, 89]\), i.e. when \( \chi(\hat{\rho}; x) = e^{-\frac{1}{4}x^T\sigma x + im \cdot x} \) for some mean vector \( m \) and covariance matrix \( \sigma \). Given now an input \( n_I \)-mode CV system with Hilbert space \( \mathcal{H}_I \), and an output \( n_O \)-mode system with Hilbert space \( \mathcal{H}_O \), a BGC \( \Phi : \mathcal{D}(\mathcal{H}_I) \to \mathcal{D}(\mathcal{H}_O) \) is a CPTP map \([64]\) that preserves the gaussian character of the transmitted signals. These transformations can be formally described by assigning a vector \( v \in \mathbb{R}^{2n_O} \) and matrices \( Y \in \mathbb{R}^{2n_O \times 2n_I} \), \( X \in \mathbb{R}^{2n_I \times 2n_O} \) that verify the condition \( Y \geq (\gamma_{n_O} - X\gamma_{n_I} X^T) \) with \( \gamma_{n} := (-\frac{1}{n}, \frac{1}{n}) \) being a \( 2n \times 2n \) block matrix. Explicitly given \( \hat{\rho} \in \mathcal{D}(\mathcal{H}_I) \) the state describing the input signal of the channel, the characteristic function of the corresponding state \( \Phi(\hat{\rho}) \) at the end of the transmission line can be written as \( \chi(\Phi(\hat{\rho}); x) = \chi(\hat{\rho}; X'TX) e^{-\frac{1}{4}x^TYx + iv \cdot x} \), implying the identities

\[
   m(\Phi(\hat{\rho})) = Xm(\hat{\rho}) + v, \quad \sigma(\Phi(\hat{\rho})) = X\sigma(\hat{\rho})X^T + Y.
\]

(1)

A BGC map \( \Phi \) is finally said to be Phase-Insensitive (PI) if for all input states \( \hat{\rho} \in \mathcal{D}(\mathcal{H}_I) \), and for all \( t \in \mathbb{R} \) we have

\[
   \Phi(e^{-i\hat{H}_I t} \hat{\rho} e^{i\hat{H}_I t}) = e^{i\hat{H}_O t}\Phi(\hat{\rho})e^{\pm i\hat{H}_O t},
\]

(2)

with \( \hat{H}_I \) and \( \hat{H}_O \) the free Hamiltonians of \( \mathcal{H}_I \) and \( \mathcal{H}_O \) respectively (specifically a \( \Phi \) verifying (2) with the upper signs in the r.h.s. is said to be gauge-covariant). From a practical point of view the multimode PI-BGCs models described here provide an idealized yet commonly used version of broadband communication lines, because they characterize quantum states transferred through an optical medium via electromagnetic pulses whose bandwidth is small compared to their central reference frequency \([61, 68–70]\).

**Quantum Work-Extraction:** At variance with purely classical settings, discriminating which part of the internal energy of a quantum system (e.g. the output signal of a QEL) can be identified with heat or work is difficult \([71–73]\) due to correlation-induced entropy increases that may arise when coupling the system to an external load \([75]\). Nonetheless, limiting the allowed operations to be local, fully reversible, and coherent (i.e. unitary), the amount of work we can extract from a single copy of a density matrix \( \hat{\rho} \) of a system is given by the ergotropy functional \( E(\hat{\rho}) \) \([76]\). Letting \( E(\hat{\rho}) := \text{Tr} [\hat{\rho}\hat{H}] \), we can write

\[
   E(\hat{\rho}) := E(\hat{\rho}) - E(\hat{\rho}^+),
\]

(3)

where \( \hat{\rho}^+ \) is the passive counterpart \([90, 91]\) of \( \hat{\rho} \), i.e. the special element of \( \mathcal{D}(\mathcal{H}) \) which has the lowest energy among those with the same spectrum of \( \hat{\rho} \) \([92]\). Since passive states are not necessarily completely passive \([93, 94]\), ergotropy turns out to be a non-extensive, super-additive quantity. Accordingly, when operating with reversible coherent operations on \( N \) copies of a given state \( \hat{\rho} \), it is possible to increase the total amount of extractable energy by acting jointly on the whole set of subsystems. The maximum amount of energy per copy that is attainable under this new paradigm is quantified by the total ergotropy \( E_{\text{tot}}(\hat{\rho}) \), a functional fulfilling the inequality \( E_{\text{tot}}(\hat{\rho}) \geq E(\hat{\rho}) \) which can obtained via a proper regularization of (3), i.e.

\[
   E_{\text{tot}}(\hat{\rho}) := \lim_{n \to \infty} \frac{1}{n} E(\hat{\rho}^\otimes n) = \mathbb{E}(\hat{\rho}) - E(\tilde{T}_{\beta}(\hat{\rho})),
\]

(4)

where in the last identity \( \tilde{T}_{\beta} := e^{-\beta\hat{H}} / \text{Tr} [e^{-\beta\hat{H}}] \) is a thermal Gibbs state of the system whose inverse temperature \( \beta \in \mathbb{R}^+ \) is fixed in order to ensure \( S(\tilde{T}_{\beta}(\hat{\rho})) = S(\hat{\rho}) := -\text{Tr} [\hat{\rho} \log \hat{\rho}] \), \( E_{\text{tot}}(\hat{\rho}) \) represents the ultimate amount of energy that we can extract reversibly from \( \hat{\rho} \) when having at disposal an unlimited number of copies. More energy from the system can still be converted into useful work only if we are willing to admit some dissipation side-effect, e.g. by coupling the system with an external thermal bath \([75, 78]\). In this case the overall amount of extractable energy is provided by the non-equilibrium free energy functional: \( F_{\beta}(\hat{\rho}) := \mathbb{E}(\hat{\rho}) - S(\hat{\rho}) / \beta \), with \( \beta \) representing the inverse temperature of the bath.

**Optimal inputs for PI-BGCs:** Here we present our main result: input coherent states \([63]\) maximize the three functionals introduced in the previous sections at
the output of any PIBGC. To this aim we first observe
the following fact:

**Theorem 1.** Given $\Phi$ a PI-BGC from $n_I$ input to $n_O$ output
modes, for any $\hat{\rho} \in \mathcal{D}(\mathcal{H}_I)$ there exists at least a
coherent input state $\hat{\varphi} \in \mathcal{C}(\mathcal{H}_I)$ having the same mean
input energy of $\hat{\rho}$ such that $\mathcal{E}(\Phi(\hat{\varphi})) \geq \mathcal{E}(\Phi(\hat{\rho}))$.

**Proof.** We recall that the mean energy of a quantum state $\hat{\rho} \in \mathcal{D}(\mathcal{H})$ of $n$ modes can be expressed in terms of its
statistical mean and covariance matrix via the compact expression $\mathcal{E}(\hat{\rho}) = \frac{\text{Tr}[m(\hat{\rho})^2]}{2} - n/2$. Recall also
that the coherent states $\hat{\varphi}$ of a $n_I$-mode CV system are
characterized by its statistical mean $m$: $|\varphi\rangle = \hat{D}(m) |0\rangle$ with $|0\rangle$ being the vacuum state of
the model. Thanks to this identity and to Eq. (1), the mean
energy at the output of a BGC $\Phi$ defined by the vector $v$ and the matrices $X$, $Y$ can be expressed as $\mathcal{E}(\Phi(\hat{\rho})) = $ $\frac{\text{Tr}[X^T X \sigma(\hat{\rho})]}{2} + \frac{\text{Tr}[X^T X \rho]}{2} + c$, where $c = \text{Tr}[Y]/4 - n_O/2$ is a constant that is independent from the input state $\hat{\rho}$. Next we remind that any PI-BGC has $v = 0$ and admits
an orthogonal, symplectic transformation $V \in \mathbb{R}^{2n_I \times 2n_I}$; such that the following statement holds [63, 95]:

$$(V^T X V)^T)_{jk} = \Lambda_j \delta_{jk},$$

(5)

with $\Lambda_m = \Lambda_{m+n_I}$, $\forall m = 1, \ldots, n_I$, and $\Lambda_m \geq \Lambda_{m+1}$, $\forall m = 1, \ldots, n_I$. Observe that the above conditions are equivalent
to saying that $\sqrt{\Lambda_1}$ is the highest singular eigenvalue of $X$, or equivalently that for every vector $w \in \mathbb{R}^{2n_I}$ it holds $|Xw|^2 \leq \Lambda_1 w^2$. Now consider a coherent state $\hat{\varphi}$ with
mean vector $m(\hat{\varphi})$ oriented in such a way to saturate the former inequality, i.e. $|Xm(\hat{\varphi})|^2 = \Lambda_1 m(\hat{\varphi})^2$, that is
with a $m(\hat{\varphi})$ which is an eigenvector of the matrix $X^T X$. Notice that such condition can be fulfilled for any value
of $|m(\hat{\varphi})|$, and hence for any possible $\mathcal{E}(\hat{\varphi})$. For such a choice we can hence write the inequality

$$|Xm(\hat{\varphi})|^2 - |Xm(\hat{\rho})|^2 \geq \Lambda_1 (m(\hat{\varphi})^2 - m(\hat{\rho})^2),$$

(6)

that holds true for all $\hat{\rho} \in \mathcal{D}(\mathcal{H}_I)$. Notice also that thanks to (5) and remembering that $\sigma(\hat{\varphi}) = I_{2n_I}$, we have

$$\text{Tr}[X^T X \sigma(\hat{\rho}) - \sigma(\hat{\varphi})] = \sum_{j=1}^{2n_I} \Lambda_j \left[ (V \sigma(\hat{\rho}) V^T)_{jj} - 1 \right]$$

$$\leq \Lambda_1 \text{Tr}[V \sigma(\hat{\rho}) V^T - \sigma(\hat{\varphi})] \leq \Lambda_1 \text{Tr}[\sigma(\hat{\rho}) - \sigma(\hat{\varphi})].$$

(7)

In deriving 7 we exploited the following two facts: i) since $V$ is a symplectic matrix, then $V \sigma(\hat{\rho}) V^T$ is a covariant
matrix $\sigma(\hat{\rho})$ of a proper density matrix $\rho$ of the system;
ii) for all covariant matrices $\sigma$ it is always true that
$\sigma_{m,n} + \sigma_{m+n_I,n+m_nI} \geq 0$ for all $m = 1, \ldots, n_I$, which can be easily proven by noticing that the left-hand side is the
trace of the covariance matrix of the reduced density matrix
of the $m$-th mode of the input system and from the fact that for any $n$-mode quantum state $\text{Tr}[\sigma(\hat{\rho})] \geq 2n$, since $\mathcal{E}(\hat{\rho}) \geq 0$. Finally, using (6) and (7) we can conclude that

$$\mathcal{E}(\Phi(\hat{\varphi})) = \mathcal{E}(\Phi(\hat{\varphi}))$$

$$= \frac{|Xm(\hat{\varphi})|^2 - |Xm(\hat{\varphi})|^2}{2} - \frac{\text{Tr}[X^T X (\sigma(\hat{\varphi}) - \sigma(\hat{\rho}))]}{4}$$

$$\geq \Lambda_1 \left[ (m(\hat{\varphi})^2 - m(\hat{\rho})^2) - \frac{\text{Tr}[\sigma(\hat{\rho}) - \sigma(\hat{\varphi})]}{4} \right] \leq \Lambda_1 \left[ \mathcal{E}(\hat{\varphi}) - \mathcal{E}(\hat{\rho}) \right] \geq 0,$$

which evaluated in the case where $\hat{\varphi}$ and $\hat{\rho}$ shares the
same input energy (i.e. $\mathcal{E}(\hat{\varphi}) = \mathcal{E}(\hat{\rho})$) implies $\mathcal{E}(\Phi(\hat{\varphi})) \geq \mathcal{E}(\Phi(\hat{\rho}))$, hence the thesis. \Box

Exploiting the above result we are now ready to present our main finding:

**Theorem 2.** Given $\Phi$ a PI-BGC from $n_I$ input to $n_O$ output
modes, for any $E \in \mathbb{R}^+$ and $\hat{\rho} \in \mathcal{D}(\mathcal{H}_I)$ with
$\mathcal{E}(\hat{\rho}) \leq E$ there exists a coherent state $\hat{\varphi} \in \mathcal{D}(\mathcal{H}_I)$ with
$\mathcal{E}(\hat{\varphi}) = E$ that achieves higher values of the output
entropy, max entropy, and non-equilibrium free-energy functionals, i.e.

$$\mathcal{E}(\Phi(\hat{\varphi})) \geq \mathcal{E}(\Phi(\hat{\rho})), \quad \mathcal{E}_{\text{tot}}(\Phi(\hat{\varphi})) \geq \mathcal{E}_{\text{tot}}(\Phi(\hat{\rho})), \quad \mathcal{F}^\beta(\Phi(\hat{\varphi})) \geq \mathcal{F}^\beta(\Phi(\hat{\rho})), \quad \forall \beta > 0.$$

(9)

**Proof.** The entropy, the total entropy, and the non-equilibrium free energy are all Schur convex functional
of the states (see [92] for details, which includes Refs. [96–100]). Now in Refs. [83, 84] it has been shown that
coherent states optimize the output of BGCs with respect to every Schur-convex functional. Therefore, given $\mathcal{E}(\hat{\rho}) \leq E$ and every coherent state $\hat{\varphi}$ we can write

$$\mathcal{E}(\Phi(\hat{\varphi})) \leq \mathcal{E}(\Phi(\hat{\rho}))^2, \quad \mathcal{E}(\hat{\rho}(\Phi(\hat{\varphi}))) \leq \mathcal{E}(\hat{\rho}(\Phi(\hat{\varphi}))), \quad \mathcal{F}^\beta(\Phi(\hat{\varphi})) \leq \mathcal{F}^\beta(\Phi(\hat{\rho})).$$

(10)

The thesis now immediately follows from the above expressions and from Theorem 1 which guarantees that
there is at least a coherent state $\hat{\varphi}$ with mean energy greater or equal to $E$ that fulfills the inequality $\mathcal{E}(\Phi(\hat{\varphi})) \geq \mathcal{E}(\Phi(\hat{\rho})）。$ \Box

**One-mode PI-BGCs:** In the special case of one
mode (i.e. $n_I = n_O = 1$) PI-BGCs, some simplification
occurs that allows us to extend a little further the result
of the previous section. First we remark that in this
context passivity and complete passivity are equivalent
notions[63]:

$$\mathcal{E}(\hat{\tau}) = \mathcal{E}_{\text{tot}}(\hat{\tau}) \quad \forall \hat{\tau} \text{ one-mode Gaussian states.}$$

(11)

In this particular setting the energy at the output of PI-
BGCs $\mathcal{E}(\Phi(\rho))$ depends only on the input energy $\mathcal{E}(\rho)$, using both this fact and the main result of [101], one can prove the following statement:

**Theorem 3.** Given $\Phi$ a one-mode PI-BGC and for any
$E, s \in \mathbb{R}^+$ and one-mode bosonic state $\hat{\rho}$ with $\mathcal{E}(\hat{\rho}) \leq E$ and $s(\hat{\rho}) \geq s$, there exists a gaussian state $\hat{\tau}$ with mean energy $E$ and entropy $s$, that achieves higher values of
the output ergotropy, max ergotropy, and non-equilibrium free-energy functionals, i.e.

\[ E(\Phi(\hat{\tau})) = E_{\text{tot}}(\Phi(\hat{\tau})) \geq \mathcal{E}(\Phi(\hat{\rho})) , \]
\[ F^\beta(\Phi(\hat{\tau})) \geq F^\beta(\Phi(\hat{\rho})) , \quad \forall \beta > 0 . \]

(12)

It is easy to notice that in this scenario Theorem 2 is a special instance (s=0) of the result above.

All one-mode PI-BGCs can be expressed as compositions of three maps [89]: the lossy thermal channel \( L_{\eta,N} \), describing the interaction with a thermal environment of mean photon number \( N \geq 0 \) through a beam-splitter of transmissivity \( \eta \in [0,1] \) \( (X = \sqrt{\eta}I_2; \ Y = (1 - \eta)(2N + 1)I_2) \); the additive classical noise channel \( N_N \) [106–114], describing the interaction with a thermal environment through a linear optical amplifier of gain \( \mu \geq 1 \) \( (X = \sqrt{\mu}I_2; \ Y = (\mu - 1)(2N + 1)I_2) \); and the additive classical noise channel \( N_N \) describing a random displacement of the signal in the phase space \( (X = I_2; \ Y = 2NI_2) \). It follows that, constraining the input energy to be \( E(\hat{\rho}) \leq E \), the maximum ergotropy (and total ergotropy) achievable at the output are respectively \( \mathcal{E}_E^{(\text{max})}(L_{0,N}) = \eta E \), \( \mathcal{E}_E^{(\text{max})}(A_{\mu,N}) = \mu E \), and \( \mathcal{E}_E^{(\text{max})}(N_N) = E - \eta \) for details. Notice that the reported values do not depend upon \( N \) and exhibit the multiplicative behaviour found in [102], where an optimization of the output ergotropy for \( L_{\eta,N} \) and \( A_{\mu,N} \) was performed on the restricted setting of Gaussian inputs.

**BGCs which are not PI:**—If we drop the phase invariance assumption (2), coherent states \( \Phi \) no longer represent the optimal choices for the output work-extraction functionals: in this case the problem is made more complex by the fact that now the channel does not admit a single input state \( \hat{\rho} \) that maximizes the positive contribution of \( \mathcal{E}(\Phi(\hat{\rho})) \), \( E_{\text{tot}}(\Phi(\hat{\rho})) \), and \( F^\beta(\Phi(\hat{\rho})) \) (i.e. the term \( \mathcal{E}(\Phi(\hat{\rho})) \)), and at the same time minimizes the negative one (e.g. \( \mathcal{E}(\Phi(\hat{\rho})^+ \Phi) \) for the ergotropy). One-mode not phase invariant BGC channel are able to describe energy exchanges of the transmitted signals with a squeezed vacuum environment [103, 104]. In [92] we consider in full generality one-mode BGCs. To elucidate the difficulty of the problem, here we show the example of the map \( \Gamma_{\eta,\zeta} := L_{\eta,0} \circ \Sigma_\zeta \), results from a concatenation of a squeezing unitary evolution \( (X = (\sqrt{\zeta} \ I_{2N}) \); \( Y = 0 \) that precedes the action of a quantum-limited attenuator (here \( \zeta \geq 1 \), with \( \zeta = 1 \) corresponding to the zero-squeezing case). On one side, for this channel the pure displaced-squeezed states \( \hat{\rho}_1 \) having covariance matrix \( \sigma(\hat{\rho}_1) = (\zeta^\nu \ I_{2N}) \) can easily be shown to provide the output configurations that majorizes all the others [105], minimizing the negative contributions of \( \mathcal{E}(\Gamma_{\eta,\zeta}(\hat{\rho}_1)) \), \( E_{\text{tot}}(\Gamma_{\eta,\zeta}(\hat{\rho}_1)) \), and \( F^\beta(\Gamma_{\eta,\zeta}(\hat{\rho}_1)) \) by the same Schur-convex argument we used before – indeed, with this choice \( \Sigma_\zeta(\hat{\rho}_1) \) becomes a coherent state, and the result follows directly from Refs. [83, 84] by observing that \( L_{\eta,0} \) is phase-insensitive. On the other hand, let \( \hat{\rho}_2 \) be the gaussian state with moments \( m(\hat{\rho}_2) = m(\hat{\rho}_1) \) and \( \sigma(\hat{\rho}_2) = (\zeta^\nu \ I_{2N}) \). It is not difficult to see that \( \hat{\rho}_2 \) has the same energy as \( \hat{\rho}_1 \), but that \( \mathcal{E}(\Gamma_{\eta,\zeta}(\hat{\rho}_2)) > \mathcal{E}(\Gamma_{\eta,\zeta}(\hat{\rho}_1)) \) for all \( \zeta \geq 1 \), preventing \( \hat{\rho}_1 \) from being the optimal choice for the positive contribution of the output work extraction functionals.

A partial solution of the optimal work preservation problem at the output of non-PI BGCs is presented in Ref. [92] where, focusing on one-mode (not-PI) BGCs, we provide an analytical characterization of the maximal output ergotropy \( \mathcal{E}_{E,G}^{(\text{max})} \) achievable using energy constrained Gaussian inputs (incidentally, thanks to (11) these values also coincide with the Gaussian maximal values of the output total ergotropy). The results we obtained are summarised in Fig. 1, where we plot the ratio \( \mathcal{E}_{E,G}^{(\text{max})}/E \) for different types of channels \( \Gamma_{\eta,\zeta} = L_{\eta,0} \circ \Sigma_\zeta \) and \( \Theta_{\mu,\zeta} = A_{\mu,0} \circ \Sigma_\zeta \) obtained respectively by composing attenuator and amplifying channels with squeezing operations. Notice that the presence of squeezing tends to boost the ergotropy through by yielding values of the ratio which can exceed 1 even in the presence of attenuation, and that in the high energy limit the solutions approach the asymptotic limits \( \lim_{E \to \infty} \mathcal{E}_{E,G}^{(\text{max})}(\Gamma_{\eta,\zeta})/E = \eta \zeta \) and \( \lim_{E \to \infty} \mathcal{E}_{E,G}^{(\text{max})}(\Theta_{\mu,\zeta})/E = \mu \zeta \), respectively.

**Conclusions:**—The study of QELs paves the way to design improvements for quantum batteries or quantum thermal engines by facilitating the interconnections between cluster of such devices, and contributing to the stabilizing protocols for preserving the energy stored within [106–114]. Generalization of the present approach...
to finite-dimensional setting may represent an interesting theoretical research line.

We thank G. M. Andolina, F. Belliard, and M. Fanizza for insightful discussions. We acknowledge support by MIUR via PRIN 2017 (Progetto di Ricerca di Interesse Nazionale): project QUSHIP (2017SRNBKR).

Supplemental material for Quantum Energy Lines
and the optimal output ergotropy problem

The Supplemental material is organized as follows: in Sec. 1 we review the notion of passive and completely passive states; in Sec. 2 we discuss Shur convexity and convexity properties of our figure of merit; in Sec. 3 instead we give a detailed account of the optimization for the work extraction at the output of one-mode BGCs.

1 Passive and Completely Passive states

Here we clarify the notion of passive counterpart of quantum state which enters in the definition of the ergotropy and the total ergotropy (a quantity that is sometime called asymptotic ergotropy [1]) given in Eqs. (3) and (4) of the main text.

By the spectral theorem we can decompose any (non necessarily passive) state of the system as

$$\hat{\rho} = \sum_{k \in \mathbb{N}} p_k |\Phi_k\rangle \langle \Phi_k|,$$

where the set \{ |\Phi_k\rangle \} \in \mathbb{N} is an orthonormal basis on the space \mathcal{H}, and \( p_k \) are probabilities which we can list in decreasing order \( p_{k+1} \leq p_k \) without loss of generality. The passive counterpart of \( \hat{\rho} \) is hence defined as the density matrix

$$\hat{\rho}^\downarrow = \sum_{k \in \mathbb{N}} p_k |F_k\rangle \langle F_k|,$$

(1)

where \( |F_k\rangle \) are the Fock eigenstates of \( \hat{H} \) ordered such that \( \hat{H} |F_k\rangle = \varepsilon_k |F_k\rangle \) and \( \varepsilon_{k+1} \geq \varepsilon_k \). Since \( \hat{\rho} \) and \( \hat{\rho}^\downarrow \) share the same spectrum it is clear that they are related by a unitary mapping, in particular we can write

$$\hat{\rho}^\downarrow = \hat{V} \hat{\rho} \hat{V}^\dagger,$$

$$\hat{V} := \sum_{k \in \mathbb{N}} |F_k\rangle \langle \Phi_k|.$$

(2)

Passive states are such that their mean energy can not decrease after any transformation \( \hat{V} \) of the unitary set \( U(\mathcal{H}) \) [2, 3], i.e.

$$\mathcal{E}(\hat{\rho}^\downarrow) \leq \mathcal{E}(\hat{V} \hat{\rho} \hat{V}^\dagger),$$

(3)

where \( \mathcal{E}(\hat{\rho}) = \text{Tr}[\hat{H} \hat{\rho}] \) is the mean energy functional of the model.

In general, the state \( \hat{\rho}^\downarrow \otimes \hat{\rho}^\downarrow \) is not a passive state, so we can introduce the condition of complete passivity [4]: a state is completely passive if \( \forall k \in \mathbb{N} (\hat{\rho}^\downarrow)^{\otimes k} \) is a passive state. It can be proven [3, 4] that a state whose support is not entirely contained in the ground state of the Hamiltonian is completely passive if and only if it is a Gibbs state \( \hat{\tau}_\beta \), that is if

$$\hat{\tau}_\beta := \frac{\exp[-\beta \hat{H}]}{\text{Tr}[\exp[-\beta \hat{H}]]},$$

(4)

arXiv:2104.11255v3 [quant-ph] 28 Nov 2021
for some \( \beta \in \mathbb{R}^+ \). Accordingly the completely passive counterpart of a quantum state \( \hat{\rho} \) corresponds to the Gibbs state \( \hat{\tau}_B(\hat{\rho}) \) which share the same von Neumann entropy with the state \( \hat{\rho} \), i.e.,

\[
S(\hat{\tau}_B(\hat{\rho})) = S(\hat{\rho}). \tag{5}
\]

## 2 Shur convexity and concavity properties of the work extraction functionals

Now we recall the concept of majorization [5, 6]. Given two states \( \hat{\rho} = \sum_{k \in \mathbb{N}} p_k |\Phi_k\rangle \langle \Phi_k| \) and \( \hat{\xi} = \sum_{k \in \mathbb{N}} q_k |\phi_k\rangle \langle \phi_k| \) with their eigenvalues arranged in decreasing order, we say that \( \hat{\rho} \) majorizes \( \hat{\xi} \) if

\[
\hat{\rho} \succ \hat{\xi} \iff \forall k \in \mathbb{N} \sum_{j=0}^k p_j \geq \sum_{j=0}^k q_j , . \tag{6}
\]

Given a function \( f : \mathcal{D}(\mathcal{H}) \to \mathbb{R} \) we say that \( f \) is Schur-convex if

\[
\hat{\rho} \succ \hat{\xi} \Rightarrow f(\hat{\rho}) \geq f(\hat{\xi}), \tag{7}
\]

on the contrary we call \( f \) Schur-concave if

\[
\hat{\rho} \succ \hat{\xi} \Rightarrow f(\hat{\rho}) \leq f(\hat{\xi}) . \tag{8}
\]

The output of any Schur-convex functional is optimised by coherent states:

**Lemma 1.** Let \( f(\hat{\rho}) \) be any Schur-convex function of a quantum state \( \hat{\rho} \).

**Lemma 2.** The energy \( \mathcal{E}(\hat{\rho}^\downarrow) \) of the passive state associated to \( \hat{\rho} \) is a Schur-concave functional of \( \hat{\rho} \).

**Proof.** The proof of this statement can be found in the appendix B of Ref. [7]. \qed

**Lemma 3.** The Von Neumann entropy \( S(\hat{\rho}) \) is a Schur-concave functional of \( \hat{\rho} \).

**Proof.** This is a classic result for Hilbert spaces of finite dimension [8], which in Ref. [9] is generalised to infinite-dimensional Hilbert spaces. \qed

**Lemma 4.** The thermal energy \( \mathcal{E}(\hat{\tau}_B(\hat{\rho})) \) of the Gibbs state with the same entropy as \( \hat{\rho} \) is a Schur-concave functional of \( \hat{\rho} \).

**Proof.** It is straightforward to see that this quantity is a monotone in the entropy \( S(\hat{\rho}) \); the results hence follows from lemma (3). \qed

**Lemma 5.** The function ergotropy \( \mathcal{E} \) is convex on states with finite average energy.

**Proof.** Given the states \( \hat{\rho}_1, \hat{\rho}_2 \) and \( \hat{\rho}_3 = p\hat{\rho}_1 + (1-p)\hat{\rho}_2 \) with \( p \in [0,1] \), invoking (2) we find the associated passive states as:

\[
\hat{\rho}_1^\downarrow = \hat{V}_1 \hat{\rho}_1 \hat{V}_1^\dagger, \quad \hat{\rho}_2^\downarrow = \hat{V}_2 \hat{\rho}_2 \hat{V}_2^\dagger, \quad \hat{\rho}_3^\downarrow = \hat{V}_3 \hat{\rho}_3 \hat{V}_3^\dagger ,
\]

with \( \hat{V}_1, \hat{V}_2, \) and \( \hat{V}_3 \) unitaries. Then by invoking the property (3) of passive states we get

\[
p\mathcal{E}(\hat{\rho}_1^\downarrow) + (1-p)\mathcal{E}(\hat{\rho}_2^\downarrow) - \mathcal{E}(pp\hat{\rho}_1 + (1-p)\hat{\rho}_2) = p[\mathcal{E}(\hat{V}_3 \hat{\rho}_1 \hat{V}_3^\dagger) - \mathcal{E}(\hat{V}_1 \hat{\rho}_1 \hat{V}_1^\dagger)] + (1-p)[\mathcal{E}(\hat{V}_3 \hat{\rho}_2 \hat{V}_3^\dagger) - \mathcal{E}(\hat{V}_2 \hat{\rho}_2 \hat{V}_2^\dagger)] \geq 0 , \tag{9}
\]

which proves the statement. \qed
Lemma 6. The total ergotropy $E_{\text{tot}}(\hat{\rho})$ is convex on states with finite average energy.

Proof. By construction, the total ergotropy is the limit of a succession of ergotropy functions. Since the latter are convex by lemma (2), the total ergotropy is also convex. \hfill \Box

Lemma 7. For any $\beta \in (0, \infty]$, the non-equilibrium free energy $F^\beta(\hat{\rho})$ is convex on states with finite average energy.

Proof. By the definition $F^\beta(\hat{\rho})$ is the difference between a linear functional and a concave functional. Therefore it is convex. \hfill \Box

Lemma 8. For any CPTP map $\Gamma$, among the input state with energy $E(\hat{\rho}) = E$, the states that maximize the output ergotropy $E(\Phi(\hat{\rho}))$ are pure states.

Proof. In Ref. [10] it is proven that any quantum state $\hat{\rho}$ can be expressed as
\[
\hat{\rho} = \sum_{k \in \mathbb{N}} p_k |\Phi_k\rangle \langle \Phi_k|,
\]
where $|\Phi_k\rangle \langle \Phi_k|$ are pure states with energy $E(|\Phi_k\rangle \langle \Phi_k|) = E$, and $\sum_{k=1}^{\infty} p_k = 1$. Using lemma 2, we can then write
\[
E(\Gamma(\hat{\rho})) = E\left(\Gamma\left(\sum_{k \in \mathbb{N}} p_k |\Phi_k\rangle \langle \Phi_k|\right)\right) \leq \sum_{k \in \mathbb{N}} p_k E(\Gamma(|\Phi_k\rangle \langle \Phi_k|)).
\]
Therefore, by definition of mean, we can say that there exists at least one pure state $|\Phi_j\rangle \langle \Phi_j|$ such that
\[
E(\Gamma(|\Phi_j\rangle \langle \Phi_j|)) \geq \sum_{k \in \mathbb{N}} p_k E(\Gamma(|\Phi_k\rangle \langle \Phi_k|)) = E(\Gamma(\hat{\rho})). \tag{10}
\]

Lemma 9. For any CPTP map $\Gamma$, among the input state with energy $E(\hat{\rho}) = E$, the states that maximize the output total ergotropy $E_{\text{tot}}(\Phi(\hat{\rho}))$ are pure states.

Proof. It follows from lemma (6), in a completely analogous way as in the proof of lemma 8. \hfill \Box

Lemma 10. For any CPTP map $\Gamma$, among the input state with energy $E(\hat{\rho}) = E$, the states that maximize the non-equilibrium free energy $F^\beta(\Phi(\hat{\rho}))$ are pure states.

Proof. It follows from lemma (7), in a completely analogous way as in the proof of lemma 8. \hfill \Box

3 One-mode BGCs analysis

We recall that the energy of a Gaussian state can be written as
\[
E(\hat{\rho}) = \frac{\text{Tr}[\sigma(\hat{\rho})]}{4} + \frac{m(\hat{\rho})^2}{2}, \tag{11}
\]
and that ergotropy of a single-mode Gaussian states can be expressed as [11]
\[
\mathcal{E}(\hat{\rho}) = \frac{\text{Tr}(\sigma(\hat{\rho}))}{4} + \frac{m(\hat{\rho})^2}{2} - \frac{\sqrt{\det(\sigma(\hat{\rho}))}}{2}. \tag{12}
\]
The problem of optimising $\mathcal{E}(\Phi(\hat{\rho}))$ is, therefore, entirely determined by the matrices $X$ and $Y$ of the channel and by the moments $m(\hat{\rho})$ and $\sigma(\hat{\rho})$ of the input state.
3.1 PI-BGCs

For simple yet practically useful classes of one-mode PI-BGCs we can express the analytical formulas for output ergotropy and output non-equilibrium free energy. Here we consider three examples of phase-insensitive one-mode BGCs [12]: the noisy lossy channel \( L_{\eta,N} \), defined by the matrices

\[
X(L_{\eta,N}) = \sqrt{\eta}I_2, \quad Y(L_{\eta,N}) = (1 - \eta)(2N + 1)I_2 ;
\]

the noisy amplification channel \( A_{\mu,N} \), defined as

\[
X(A_{\mu,N}) = \sqrt{\mu}I_2, \quad Y(A_{\mu,N}) = (\mu - 1)(2N + 1)I_2 ;
\]

and the additive noise channel \( N_N \), defined as

\[
X(N_N) = I_2, \quad Y(N_N) = 2NI_2 .
\]

Here \( \eta \in [0, 1], \mu \in [1, \infty), \) and \( N \in \mathbb{R}^+ \) is the environmental noise term [12].

As we have proven in the main section, the optimal state will always be a coherent state \( \hat{\phi} \). For all of these three channel, the output covariance matrix \( \sigma(\Phi(\hat{\phi})) \) will be a multiple of the identity:

\[
\sigma(L_{\eta,N}(\hat{\phi})) = (2N(1 - \eta) + 1)I_2 ,
\]

\[
\sigma(A_{\mu,N}(\hat{\phi})) = (2\mu(N + 1) - 2N - 1)I_2 ,
\]

\[
\sigma(N_N(\hat{\phi})) = (2N + 1)I_2 .
\]

(16)

Now observe that when the covariance matrix is a multiple of the identity, i.e. \( \sigma(\hat{\rho}) = \alpha I_2 \), the ergotropy (12) can be simplified as

\[
\mathcal{E}(\hat{\rho}) = \frac{m(\hat{\rho})^2}{2} .
\]

(17)

Therefore, the output ergotropy given an input coherent state with energy \( E \) is:

\[
\mathcal{E}(L_{\eta,N}(\hat{\phi})) = \eta E, \quad \mathcal{E}(A_{\mu,N}(\hat{\phi})) = \mu E, \quad \mathcal{E}(N_N(\hat{\phi})) = E .
\]

By the property (12) of the main text these values also correspond to the maximum output values of the total ergotropy. The non-equilibrium free energy at fixed inverse temperature \( \beta \) is instead given by

\[
\mathcal{F}^\beta(L_{\eta,N}(\hat{\phi})) = \eta E + N(1 - \eta) - \frac{N(1 - \eta)^{\frac{1}{2}}}{\beta} \log (N(1 - \eta) + 1) + \frac{N(1 - \eta)}{\beta} \log (N(1 - \eta)) ,
\]

\[
\mathcal{F}^\beta(A_{\mu,N}(\hat{\phi})) = \mu E + (N + 1)(\mu - 1) - \frac{\mu(N + 1) - N}{\beta} \log (\mu(N + 1) - N) + \frac{\mu(N + 1) - N - 1}{\beta} \log (\mu(N + 1) - N - 1) ,
\]

\[
\mathcal{F}^\beta(N_N(\hat{\phi})) = E + N - \frac{N + 1}{\beta} \log (N + 1) + \frac{N}{\beta} \log (N) .
\]

(18)

3.2 General one-mode BGCs

In the rest of this section we want to optimize on general BGC. Since the problem becomes much more difficult we now restrict our analysis to one-mode BGCs and we only optimize on input Gaussian
states. That is, we seek to find the Gaussian state \( \hat{\rho} \), with \( \mathcal{E}(\hat{\rho}) = E \), which maximises the output ergotropy \( \mathcal{E}(\Phi(\hat{\rho})) \) for a general one-mode BGC \( \Phi \).

Lemma 2 implies that, in order to optimize on the whole convex hull of Gaussian states, it is sufficient to consider pure Gaussian states, i.e. \( \det(\sigma(\hat{\rho})) = 1 \). This condition means that the covariance matrix of a pure one-mode gaussian state \( \hat{\rho} \) must have eigenvalues \( z \) and \( z^{-1} \), where \( z > 1 \) is the degree of squeezing of the state; i.e., \( \text{Tr}[\sigma(\hat{\rho})] = z + z^{-1} \). Using (11), we can see that if \( \hat{\rho} \) is a gaussian state of energy \( E \), then

\[
m(\hat{\rho})^2 = m^2(z) := \frac{1}{2} \left( E + 1 - \frac{z + z^{-1}}{2} \right). \tag{20}
\]

This equation fixes the module of the mean value vector \( m(\hat{\rho}) \). Its optimal direction will be fixed by equation (22) below. Condition (20) limits the squeezing parameter \( z \) to a maximum value of

\[
z_{\text{max}}(E) = 2E - 1 + \sqrt{(2E - 1)^2 - 1}. \tag{21}
\]

In order to optimize the ergotropy, we have to choose the direction vector \( m(\hat{\rho}) \) (whose module is fixed by (20)) in order to satisfy

\[
m^2(\Phi(\hat{\rho})) = |Xm(\hat{\rho})|^2 = \Lambda_1 m^2(\hat{\rho}). \tag{22}
\]

Using (12) and (22), we can express the output ergotropy as

\[
\mathcal{E}(\Phi(\hat{\rho})) = \frac{\Lambda_1}{4} \left( E + 1 - \frac{z + z^{-1}}{2} \right) + \frac{\text{Tr}[X\sigma(\hat{\rho})XT + Y]}{4}. \tag{23}
\]

We can parametrize the covariance matrix \( \sigma(\hat{\rho}) \) of a pure state in terms of two parameters \( z^* \in [1, \infty) \) and \( \theta^* \in [0, 2\pi) \) – see Eq. (27) below.

The energy value \( E \) appears in (23) only as a constant, and is therefore ininfluent in determining the optimal input. This means that, there will be an optimal covariance matrix \( \sigma^* \), characterized by parameters \( z^* \in [1, \infty) \) and \( \theta^* \in [0, 2\pi) \), which does not depend on the energy \( E \). If \( z^* < z_{\text{max}}(E) \), then the optimal state will be the one with covariance \( \sigma(\hat{\rho}) = \sigma^* \), and whose mean value \( m(\hat{\rho}) \) satisfies Eqs. (20) and (22). If instead \( z^* > z_{\text{max}}(E) \), the optimal input state will have \( m(\hat{\rho}) = 0 \) and squeezing \( z_{\text{max}} \). In particular, if \( z^* = \infty \), the optimal input will always be the maximally squeezed state available with energy \( E \). The plots in the main text are obtained by numerically finding the optimal \( \sigma^* \), and then applying the rules described above.

It is worth to notice that, for energies \( E \gg z^* \), the optimal input state \( \hat{\rho}^* \) will have almost all of its energy stored in the mean value \( m(\hat{\rho}^*) \). This implies that almost all the energy of the output state will be the (extractable) energy stored in its mean value \( m(\Phi(\hat{\rho}^*)) = \sqrt{\Lambda_1} m(\hat{\rho}^*) \). Therefore, the asymptotic behaviour for large energies will be

\[
\max_{\mathcal{E}(\hat{\rho}) = E} \mathcal{E}(\Phi(\hat{\rho})) \approx \Lambda_1 E, \tag{24}
\]

with

\[
\max_{\mathcal{E}(\hat{\rho}) = E} \frac{\mathcal{E}(\Phi(\hat{\rho}))}{\mathcal{E}(\Phi(\hat{\rho}))} \approx 1. \tag{25}
\]

### 3.3 Calculation of the optimal input covariance \( \sigma^* \)

If we define

\[
f_+(z) := \frac{1}{2} \left( z + z^{-1} \right) ; \quad f_-(z) := \frac{1}{2} \left( z - z^{-1} \right), \tag{26}
\]
then we can parametrize the covariance matrix of any gaussian pure state $\hat{\rho}$ as
\[
\sigma(\hat{\rho}) = f_+(z)I_2 + f_-(z)\sin(\theta)\sigma_x + f_-(z)\cos(\theta)\sigma_x, \tag{27}
\]
where $z \in [1, z_{\text{max}}(E)]$ is the degree of squeezing of $\hat{\rho}$, $\theta \in [0, 2\pi)$ is the squeezing direction, and $\sigma_x$ and $\sigma_\perp$ are Pauli matrices.

In the one-mode setting we have a useful group theoretic property, namely the fact that $SO(2) \subset Sp(2, \mathbb{R})$; also, we are interested in functionals that are quadratic in $X$, so using the singular value decomposition without loss of generality we can assume
\[
X = \begin{bmatrix} \sqrt{\Lambda_1} & 0 \\ 0 & \sqrt{\Lambda_2} \end{bmatrix}, \tag{28}
\]
with $\Lambda_1 \geq \Lambda_2$. Hence if we let
\[
Y = y_1I_2 + y_x\sigma_x + y_2\sigma_\perp, \tag{29}
\]
then, the covariance matrix $\sigma(\Phi(\hat{\rho}))$ of the output state $\Phi(\hat{\rho})$ is:
\[
\sigma(\Phi(\hat{\rho})) = X\sigma(\hat{\rho})X^T + Y
\]
\[
= \left( \frac{\Lambda_1 + \Lambda_2}{2} f_+(z) + \frac{\Lambda_1 - \Lambda_2}{2} f_-(z)\cos(\theta) + y_1 \right)I_2
\]
\[
+ \left( \sqrt{\Lambda_1 \Lambda_2} f_-(z)\sin(\theta) + y_x \right)\sigma_x
\]
\[
+ \left( \frac{\Lambda_1 - \Lambda_2}{2} f_+(z) + \frac{\Lambda_1 + \Lambda_2}{2} f_-(z)\cos(\theta) + y_2 \right)\sigma_\perp. \tag{30}
\]
So the eigenvalues of $\sigma(\Phi(\hat{\rho}))$ are:
\[
\lambda_{1,2}(z, \theta) = \left( \frac{\Lambda_1 + \Lambda_2}{2} f_+(z) + \frac{\Lambda_1 - \Lambda_2}{2} f_-(z)\cos(\theta) + y_1 \right)
\]
\[
\pm \left[ \left( \sqrt{\Lambda_1 \Lambda_2} f_-(z)\sin(\theta) + y_x \right)^2
\]
\[
+ \left( \frac{\Lambda_1 - \Lambda_2}{2} f_+(z) + \frac{\Lambda_1 + \Lambda_2}{2} f_-(z)\cos(\theta) + y_2 \right)^2 \right]^{1/2}, \tag{31}
\]
and we can write the ergotropy (12) as
\[
\tilde{E}(z, \theta) = \frac{\lambda_1(z, \theta) + \lambda_2(z, \theta)}{4} - \frac{\sqrt{\lambda_1(z, \theta)\lambda_2(z, \theta)}}{2} + \frac{\tilde{m}^2(z)}{2}
\]
\[
= \frac{\left( \sqrt{\lambda_1(z, \theta)} - \sqrt{\lambda_2(z, \theta)} \right)^2}{4} + \frac{\tilde{m}^2(z)}{2}, \tag{32}
\]
here $\tilde{E}(z, \theta) := E(\Phi(\hat{\rho}))$ and $\tilde{m}(z) := m(\Phi(\hat{\rho}))$, where $z$ and $\theta$ are the parameters of the gaussian state $\hat{\rho}$. Figure 1 shows a plot of $\tilde{E}(z, \theta) - \tilde{E}(1, 0) = \tilde{E}(z, \theta) - \frac{\tilde{m}^2(1)}{2}$, as a function of $z$ and $\theta$, for an example Gaussian channel.

For any given channel, characterized by the matrices $X$ and $Y$, and a given input energy $E$, the function (32) can be maximised numerically to find the optimal Gaussian state. In figure 2 we show the behavior of optimal ergotropy of different phase-sensitive attenuators $\Gamma_{\eta, \zeta} = L_{\eta,0} \circ \Sigma_{\zeta}$ by varying
the input energy $E$; here $\mathcal{L}_{\eta,0}$ is a quantum-limited attenuator characterized by the matrices (13), while $\Sigma_\zeta$ is a diagonal unitary squeezing with parameter $\zeta$, defined by

$$X(\Sigma_\zeta) = \begin{pmatrix} \sqrt{\zeta} & 0 \\ 0 & \sqrt{\zeta^{-1}} \end{pmatrix}, \quad Y(\Sigma_\zeta) = 0_2. \quad (33)$$

Therefore, the composite channel $\Gamma_{\eta,\zeta}$ is characterized by the matrices

$$X(\Gamma_{\eta,\zeta}) = X(\mathcal{L}_{\eta,0})X(\Sigma_\zeta) = \sqrt{\eta} \begin{pmatrix} \sqrt{\zeta} & 0 \\ 0 & \sqrt{\zeta^{-1}} \end{pmatrix}, \quad Y(\Gamma_{\eta,\zeta}) = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}. \quad (34)$$

In Figure 4 we plot the optimal squeezing parameter $z^*$ for some channels in the form $\Theta_{\mu,\zeta} = \mathcal{A}_{\mu,0} \circ \Sigma_\zeta$, where $\Sigma_\zeta$ is a squeezing channel of squeezing parameter $\zeta$ (see (33)), and $\mathcal{A}_{\mu,0}$ is a quantum-limited amplifier of gain $\mu$, defined by setting $N = 0$ in (14), so that

$$X(\Theta_{\mu,\zeta}) = X(\mathcal{A}_{\mu,0})X(\Sigma_\zeta) = \sqrt{\mu} \begin{pmatrix} \sqrt{\zeta} & 0 \\ 0 & \sqrt{\zeta^{-1}} \end{pmatrix}, \quad Y(\Theta_{\mu,\zeta}) = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}. \quad (35)$$

### 3.4 Special cases

We now focus on the special case in which the matrix $Y$ is diagonal in the base of the squeezing, i.e. $y_z = 0$. Replacing (31) into (32) and deriving we can see that, when $y_z = 0$, $\frac{\partial^2 \tilde{\mathcal{E}}(z,\theta)}{\partial z^2} = 0$, for any fixed value of the squeezing parameter $z$, the maximum and the minimum value of $\tilde{\mathcal{E}}(z,\theta)$ are reached when $\theta = 0$ and $\theta = \pi$, so the covariance matrix must be diagonal in the squeezing basis and its eigenvector with the largest eigenvalue must be parallel to the one of the squeezing matrix. The optimal squeezing $z^*$ can then be found by setting $\frac{\partial^2 \tilde{\mathcal{E}}(z,\theta)}{\partial z^2} = 0$, i.e. by solving the eight-grade equation

$$\frac{\partial \tilde{\mathcal{E}}(z,0)}{\partial z} = \frac{1}{4z} \left[ \frac{-2z^2\Lambda_1 + 2\Lambda_2 + 2z^2\Lambda_1 y + 2\Lambda_2 y}{\sqrt{\Lambda_1 + \Lambda_2 + 2y}} - (z^2\Lambda_1 - \Lambda_2 + 2y) + \frac{\Lambda_1 - \Lambda_2}{z} \right] = 0. \quad (36)$$

This optimal squeezing can only be reached if $z^* \leq z_{\text{max}}(E)$; otherwise the optimal allowed gaussian state will be the one with maximal squeezing $z_{\text{max}}(E)$. The maximum ergotropy will then be given by

$$\max \mathcal{E}(\Phi(\rho)) = \begin{cases} \tilde{\mathcal{E}}(\min(z^*, z_{\text{max}}(E))), 0 & \text{if } z^* \geq 1; \\ \tilde{\mathcal{E}}(\min((z^*)^{-1}, z_{\text{max}}(E))), \pi & \text{if } 0 < z^* \leq 1. \end{cases} \quad (37)$$

In the above scenario it can be interesting to consider the stronger condition $y_Z = y_X = 0$; in this case $Y$ is proportional to the identity matrix and $\mathcal{E}$ (36) can be greatly simplified to a fourth-grade equation:

$$\frac{\partial \tilde{\mathcal{E}}(z,\theta)}{\partial z} = \frac{1}{4z} \left[ y_1 \frac{\Lambda_2 z^2 - \Lambda_1}{\sqrt{\Lambda_1 + \Lambda_2} y} + \frac{\Lambda_1 - \Lambda_2}{z} \right] = 0. \quad (38)$$
Figure 1: Difference $\Delta \mathcal{E} := \mathcal{E}(\Phi(\hat{\rho})) - \mathcal{E}(\Phi(\hat{\varphi}))$ between the ergotropy $\mathcal{E}(\Phi(\hat{\rho}))$ of the output a gaussian state $\hat{\rho}$ squeezed of $z$ along the direction $\theta$, and the ergotropy $\mathcal{E}(\Phi(\hat{\varphi}))$ of a coherent state $\hat{\varphi}$ with the same energy as $\hat{\rho}$ and with optimal $m(\hat{\varphi})$, for a one-mode BCG with $\Lambda_1 = 2, \Lambda_2 = 1.3, y_I = 1, y_X = 0.4$ and $y_Z = 0$. 
Figure 2: Ratio $\mathcal{E}_{E,G}^{(max)} / E_{out}$ between the maximum output ergotropy $\mathcal{E}_{E,G}^{(max)}$ and the output energy $E_{out}$, for the channel $\Gamma_{\eta,\zeta}$ composed by a squeezing transformation $\Sigma_{\zeta}$ followed by a quantum-limited attenuator $\mathcal{L}_{\eta,0}$, with $\eta = 0.5$, for various values of the squeezing parameter $\zeta$. 
Figure 3: Ratio $E_{E,G}^{(max)}/E$ between the maximum output ergotropy $E_{E,G}^{(max)}$ and the input energy $E$, for the channel $\Theta_{\mu,\zeta}$ composed by a squeezing transformation $\Sigma_z$, followed by a quantum-limited amplifier $A_{\mu,0}$, with $\mu = 2$ (see (34)), for various values of the squeezing parameter $\zeta$. 

![Graph showing the ratio $E_{E,G}^{(max)}/E$ for different values of $\zeta$. The graph illustrates the decrease in the ratio as $E$ increases for different values of $\zeta$.]

Figure 3: Ratio $E_{E,G}^{(max)}/E$ between the maximum output ergotropy $E_{E,G}^{(max)}$ and the input energy $E$, for the channel $\Theta_{\mu,\zeta}$ composed by a squeezing transformation $\Sigma_z$, followed by a quantum-limited amplifier $A_{\mu,0}$, with $\mu = 2$ (see (34)), for various values of the squeezing parameter $\zeta$. 

The graph shows the ratio $E_{E,G}^{(max)}/E$ for different values of $\zeta$: $\zeta = 1.00$, $\zeta = 1.75$, $\zeta = 2.50$, $\zeta = 3.25$, and $\zeta = 4.00$. The ratio decreases as $E$ increases for all values of $\zeta$. The blue line represents $\zeta = 1.00$, the orange line $\zeta = 1.75$, the green line $\zeta = 2.50$, the red line $\zeta = 3.25$, and the purple line $\zeta = 4.00$. For each value of $\zeta$, the curve shows a downward trend as $E$ increases.
Figure 4: Optimal squeezing $z^*$ for some channels $\Theta_{\mu,\zeta}$ composed by a unitary squeezing of parameter $\zeta$ followed by a quantum-limited amplifier of gain $\mu$ (as defined by the matrices in Eq. (35)).
