ABSTRACT: A male specimen of the copepod Caligus chelifer Wilson, 1905, was collected during a plankton survey carried out during February 1994 off the Mexican coasts of the eastern Gulf of Mexico (Tamaulipas state). This is the first record of this species in Mexican waters and south of the 25°N in the Northwestern Atlantic. Taxonomic illustrations of the specimen are provided.

INTRODUCTION

The genus Caligus comprises about 200 species and is one of the most widely distributed groups of parasitic copepods in the world seas. They parasitize teleosts, such as mackerels and tuna, and several species of elasmobranchs (Kabata, 1979; Cressey and Cressey, 1980).

In the Gulf of Mexico and western Caribbean Sea, 26 species of Caligus have been recognized (Cressey, 1991). Most of these specimens have been collected directly from the host; however, it is not uncommon to find caligids and their close allies captured by plankton nets as they are relatively loosely attached to their host surfaces (Kabata, 1979).

From a plankton survey carried out at the central-westernmost portion of the Gulf of Mexico, a single male of a Caligus species previously unreported in Mexican waters was collected. Although the host fish remains unknown, we present the record along with taxonomic illustrations of the specimen.

MATERIAL AND METHODS

Zooplankton from 47 stations were collected from 16-21 February, 1994, during the oceanographic cruise EMOAPII (Estudio de las Modificaciones Oceanográficas y Ambientales Producidas por la Influencia del Río Pánuco), carried out by the Estación de Investigación Oceanográfica de Tampico, on board the oceanographic vessel “Antares”. Samples were taken between the southern portion of the Tamaulipas state coastline and the northern coast of Veracruz state, off the Laguna de Tampico (21°45'0.72" N; 22°49'18" N; 97°21'15"0.72" and 97°48'4.32" W). The specimen of Caligus was sorted from a sample collected at station 10 (22°23.43'N; 97°41.00'W), on February 18 at 06:52 h. It was then processed for identification. All the taxonomically relevant structures were illustrated. The specimen is deposited in Dr. Kim’s collection at the Kangreung National University, South Korea.

RESULTS AND DISCUSSION

The taxonomic analysis of the specimen resulted in the identification of a male Caligus chelifer Wilson, 1905, which was illustrated showing the main taxonomic features of the genus (Figures 1 and 2). The male of this species can be readily distinguished from the other species of Caligus by the slender, tapering urosome (Figure 1) and the presence, on the corpus of the maxilliped, of a strong projection which gives the appendage a chelate appearance when the claw is set in resting position (Wilson, 1905; Kabata, 1972; Cressey and Cressey, 1980) (see Figure 1H).

The specimen had a total length of 4.15 mm, and the cephalothorax is 2.38 mm long and 1.63 mm wide. Genital complex measured 0.74 mm long and 0.53 mm wide. Our specimen seems to be a small one when comparing it with the measurements reported by Wilson (1905) for the type specimen (total length: 4.93 mm, cephalothorax length: 3 mm, width: 2.1 mm, genital complex: 1.0 mm) and for additional, larger specimens (6-6.5 mm, 3 mm, 2.3 mm, 1.6 mm, respectively) (Wilson, 1905; Cressey, 1991).

Caligus chelifer has a 2-segmented exopod of leg 4 (Figure 2E); its first segment bears a spine on outer distal corner; the distal segment has a spine on midlength of outer margin, plus 3 large terminal spines. Of all the species recorded for the Gulf of Mexico and the Caribbean Sea (Wilson, 1936; Yamaguti, 1963; Cressey, 1991), half of them show this leg 4 segmentation and armament (C. afurcatus Wilson, 1913; C. asperimanus Pearse, 1951; C. berychis Wilson, 1936; C. bonito Wilson, 1905; C. epinephali Yamaguti, 1936; C. haemulonis Krøyer, 1863; C. mutabilis Wilson, 1905; C. ocyurus Cressey, 1991; C. praetextus Bere, 1936; C. productus Dana, 1852; C. rufimaculatus Wilson, 1905; C. suffuscus Wilson, 1913; C. xystercus Cressey, 1991). Only three of these (C. mutabilis, C. ocyurus and C. praetextus) have the genital complex and caudal rami longer than wide, as in C. chelifer. Particularly, C. chelifer resembles C. praetextus as both
Figure 1. *Caligus chelifer*, adult male: A. Habitus, dorsal; B. urosome, dorsal; C. antennule; D. antenna; E. postanntenary process; F. maxillule; G. maxilla; H. maxilliped. Scales: A= 0.5 mm; B= 0.2 mm; C-E, G, H = 0.1 mm; F= 0.05 mm.
Figure 2. Caligus chelifer, adult male: A. sternal furca; B. leg 1; C. leg 2; D. leg 3; E. leg 4. Scales A-E = 0.1 mm.
bears a triangular genital complex, with a distinctly slender and inward directed caudal rami. The main differences between these two species are found in the shape of the cephalothorax, which is narrower in *C. chelifer* (the 3 setae on exopod inner margin are relatively shorter in *C. chelifer*), and in the spine on the first exopodal segment of leg 3, which is quite broad in *C. praetextus*. *Caligus productus* is also related to *C. chelifer*; both share a 4-segmented leg 4 with three apical setae (in *C. chelifer* the first one is twice as long as the other two, while in *C. productus* the first seta is only slightly longer). Neither of these species show lateral processes of sternal furca, and the fourth exopodal seta of leg 1 terminal segment is much longer than the remaining three (in *C. chelifer* the third seta is relatively longer than in *C. productus*). Both species differ in the structure of the maxilliped and the marginal ornamentation of leg 2 endopod.

Although the host of our specimen of *C. chelifer* remains unknown, this species has been collected from three fish species that occur in the Gulf of Mexico (Hoese and Moore 1977): the Atlantic cutlassfish (*Trichiurus lepturus* Linnaeus 1758), a menhaden (*Brevoortia gunteri* Hildebrand 1948) and a swordfish (*Xiphias gladius* Linnaeus 1758) (Wilson 1905). Other records are from off Miami, and from *Brevoortia tyrannus* (Latrobe 1802), collected off Port Aransas, Texas (Cressey 1991). *Caligus chelifer* has not been reported south of 25°N. The present record represents the first record of this species in Mexican waters and allows a southward extension of its known latitudinal distribution into the tropical zone of the Northwestern Atlantic.

**ACKNOWLEDGMENTS**

Dr. Ju-Shey Ho kindly supported our work and made suggestions to improve this manuscript. We also thank the officers of the Estación de Investigación Oceánográfica de Tampico, of the Mexican Secretaría de Marina for allowing us to study the zooplankton samples from the EMOAPII cruise.
