The diversity of class D $\beta$-lactamases mediating resistance to $\beta$-lactams has been increasingly reported recently. In this study, a novel class D oxacillinase named OXA-830 was identified in a fully sequenced Aeromonas simiae strain, which was isolated from sewage discharged from a farm in southern China. OXA-830 shares the highest amino acid identity of 79.3% with an OXA-12-like variant named OXA-725. When expressed in E. coli DH5α, OXA-830 conferred resistance to penicillins and selected $\beta$-lactamase inhibitors but not to cephalosporins and carbapenems. Kinetic analysis of OXA-830 revealed a broad substrate profile including penicillins, cefazolin, cefoxitin, and ceftazidime but not carbapenems. The hydrolytic activity was significantly inhibited by sulbactam, followed by tazobactam, but was less effectively inhibited by clavulanic acid. The $\text{bla}_{\text{OXA}}-830$ gene was located on the A. simiae A6 chromosome and the $\text{bla}_{\text{OXA}}-830$-related region was bracketed by a pair of perfect inverted repeats.

Keywords: oxacillinase, OXA-830, Aeromonas simiae, resistance, kinetic analysis

INTRODUCTION

The genus Aeromonas is a distinct group of oxidase-positive, facultatively anaerobic, Gram-negative bacilli of the family Aeromonadaceae (Colwell et al., 1986). Members of Aeromonas can be isolated from every environmental niche where bacterial ecosystems exist, including aquatic habitats and fish as well as food products, and are implicated in human and animal infections (Janda and Abbott, 2010). The species Aeromonas simiae was first described in two strains (CIP 107798 and CIP 107797) isolated from feces of healthy monkeys from Mauritius (Harf-Monteil et al., 2004). Further study revealed that these two strains may originate from the same clone because they share entirely identical 16S rRNA, gyrB, and rpoD genes with each other (Saavedra et al., 2006). To date, there have been a large number of reports about the presence of $\beta$-lactamase genes among Aeromonas strains (Carvalho et al., 2012; Chen et al., 2012).

Oxacillin-hydrolyzing (OXA)-type $\beta$-lactamases (OXAs) constitute most of the members of Ambler class D active-serine-site $\beta$-lactamases (Bush et al., 1995) and are widely identified among clinically relevant Gram-negative bacteria, such as Pseudomonas spp., Acinetobacter spp., Aeromonas spp. and Enterobacteriaceae (Poirel et al., 2010). Most of the OXAs possess the ability to hydrolyze cloxacillin or oxacillin at a rate of >50% that for benzylpenicillin and are typically not inhibited by commercially available $\beta$-lactamase inhibitors such as clavulanic acid, tazobactam,
and sulbactam (Payne et al., 1994; Bush et al., 1995). According to the Bush functional classification scheme for β-lactamases (Bush et al., 1995), OXAs are classified into group 2d. Although most of the early identified OXAs exhibited a substrate profile strictly restricted to penicillin, oxacillin, cloxacillin and nitrocefin, several OXA members have been demonstrated to be active against extended-spectrum cephalosporins which is typically due to a small number of point mutations occurring in parental narrow-spectrum class D β-lactamases (DBLs), such as the derivatives of OXA-10 (Poirel et al., 2010; Leonard et al., 2013).

For instance, compared to OXA-10, OXA-11 (N146S and G167D) exhibits the ability to hydrolyze ceftazidime (Hall et al., 1993); OXA-17 (N76S) has an increased hydrolytic ability for cefotaxime as well as a decreased capacity for ceftazidime (Danel et al., 1999); and OXA-19, which differed from OXA-10 by nine amino acids, can hydrolyze ceftazidime with a low activity (Mugnier et al., 1998). Some OXAs have evolved to exhibit hydrolytic activity toward β-lactams of “last resort,” i.e., carbapenems (El Garch et al., 2011; Antonelli et al., 2015).

Similar to other antimicrobial resistance genes, many OXA β-lactamase genes have been identified on both plasmids and chromosomes with diverse mobile genetic elements (MGEs), such as integrons, insertion sequences and transposons (Poirel et al., 2010). For example, the blaOXA−1-like, blaOXA−2-like, and blaOXA−10-like genes were commonly captured as gene cassettes by integrons in plasmids (Naas and Nordmann, 1999); the blaOXA−23 gene from the chromosome of Acinetobacter radioreisistens may be transferred onto plasmids diffusing into Acinetobacter baumannii through the ISAb1-based composite transposon Tn2006 or transposon-like structure named Tn2008, or a single copy of ISAb4 upstream of the gene (Corvec et al., 2007; Adams-Haduch et al., 2008); and the blaOXA−58 gene-encoding regions in A. baumannii isolated from different countries (France, Spain, Romania, and Turkey) were bracketed by ISAb3 on one side and ISAb1 or IS18 on the other side (Poirel and Nordmann, 2006). However, according to the literature, there are intrinsic chromosomally encoded OXAs in many bacterial species (Poirel et al., 2010). The first such gene, identified in 1994, originated from the chromosome of Aeromonas jandaei (formerly Aeromonas sobria), which was not associated with an integron or transposon and was named blaOXA−12 (Rasmussen et al., 1994).

In this study, for the first time, we determined the complete genome sequence of A. simiae, i.e., a sewage-derived A. simiae strain A6. Based on sequence analysis, we identified and characterized a novel chromosomally encoded DBL named OXA−830, which is quite divergent from the other OXA β-lactamases.

### MATERIALS AND METHODS

#### Bacterial Strains

The host strain A. simiae A6 carrying the blaOXA−830 gene was isolated in November 2017 from sewage discharged from a farm in Wenzhou, China. Species identification was conducted using the Vitek-60 microorganism autoanalysis system (BioMérieux Corporate, Craponne, France). Further verification was performed based on the 16S rRNA sequencing method. Moreover, considering limited resolution the 16S rRNA gene provides to discriminate among closely related species of the genus Aeromonas (Alperi et al., 2008), a multilocus phylogenetic analysis (MLPA) of the concatenated sequences of 6 housekeeping genes (gyrB, rpoD, recA, dnaJ, gyrA, and atpD) as previously reported (Beaz-Hidalgo et al., 2015) as well as whole-genome sequence-based phylogenetic analysis using kSNP3.0 (Gardner et al., 2015) were conducted to determine the evolutionary relationship of A. simiae A6 with 32 other Aeromonas sp. strains of different species. Two neighbor-joining phylogenetic trees were generated by using MEGA7 with 1,000 bootstrap replications (Kumar et al., 2016). The bacteria and plasmids used in this work are listed in Supplementary Table S1.

#### Antimicrobial Susceptibility Testing

The minimum inhibitory concentrations (MICs) were determined using the agar dilution method following the guidelines of the Clinical and Laboratory Standards Institute (CLSI). Susceptibility patterns were interpreted according to the CLSI breakpoint criteria (CLSI, 2019) and the guidelines of the European Committee on Antimicrobial Susceptibility Testing [EUCAST] (2019) for Enterobacteriaceae. No interpretation criteria were available for benzylpenicillin, benzylpenicillin/clavulanic acid, benzylpenicillin/sulbactam, oxacillin, cloxacillin and polymyxin B from CLSI (2019) and European Committee on Antimicrobial Susceptibility Testing [EUCAST] (2019). E. coli ATCC 25922 was used as a reference strain for quality control.

#### Whole-Genome Sequencing and Sequence Analysis

Whole-cell DNA of A. simiae A6 was extracted using the AxyPrep Bacterial Genomic DNA Miniprep kit (Axygen Scientific, Union City, CA, United States) and sequenced on a PacBio RS II instrument (Pacific Biosciences). The PacBio long reads were initially assembled by Canu v1.6 (Koren et al., 2017), and then two FASTQ sequence files generated using the Illumina HiSeq 2500 platform were mapped onto the primary assembly to control assembly quality and to correct possible misidentified bases by using Bwa and the Genome Analysis Toolkit (McKenna et al., 2010). The consensus sequence was obtained by a custom-derived script written in Python1. Potential open reading frames (ORFs) were predicted using Glimmer software (Delcher et al., 2007) and annotated against the UniProt/Swiss-Prot and non-redundant protein databases using the BLASTX program with an e-value threshold of 1e−5. GView was used to construct basic genomic features (Pektou et al., 2010). Annotation of MGEs and resistance genes was performed using ISfinder (Siguier et al., 2006); INTEGRALL (Moura et al., 2009); and ResFinder (Zankari et al., 2012) with default parameters. The molecular weight and pI value of OXA-830 was predicted using ProtParam2.

1https://www.python.org/
2https://web.expasy.org/protparam/
Amino acid alignment and the neighbor-joining phylogenetic tree construction of OXA-830 with other DBLs were performed using the MAFFT program and MEGA7 with a bootstrap of 1,000 replicates, respectively (Katoh and Standley, 2013; Kumar et al., 2016). Comparisons of the nucleotide sequences were performed using BLASTN. Other bioinformatics tools were written using Python (see text footnote 1) and Biopython (Cock et al., 2009).

**Cloning of the bla\(_{\text{OXA-830}}\) Gene and Expression and Purification of OXA-830**

The gene encoding OXA-830 along with its promoter was amplified by PCR using forward (5'-CGGAATTCCAGACACAGATTGGCAGCAAGCA-3') and reverse (5'-CCCAAGCTTTGCCCAGTAGAAGAAGTGA-3') primers with a pair of flanking restriction endonuclease adapters. Then, the PCR product was eluted from an agarose gel, digested with the EcoRI and HindIII, and ligated into the pUCP24 vector with a T4 DNA ligase cloning kit (Takara Bio, Inc., Dalian, China). The recombinant plasmids were transformed into competent E. coli DH5α by the calcium chloride method, and bacterial colonies were cultured on Luria-Bertani agar plates supplemented with 20 µg/mL gentamicin. The recombinant plasmids were verified by both restriction enzyme digestion and Sanger sequencing (Shanghai Sunny Biotechnology Co., Ltd., Shanghai, China). The above-mentioned E. coli BL21 transformant was grown in Luria-Bertani medium with 50 µg/mL kanamycin at 37°C. Overnight cultures were diluted 100-fold in 200 mL of Luria-Bertani medium and incubated for hours at 37°C with orbital shaking. Isopropyl-β-d-thiogalactopyranoside (IPTG) (Sigma Chemicals Co., St. Louis, MO, United States) was added to a final concentration of 1 mM until the cultures reached an OD\(_{600}\) between 0.6 and 0.8, and incubation was continued for an additional 4 h. OXA-830 was isolated from the periplasm and purified by affinity chromatography based on the instructions of the His-tag Protein Purification Kit (P2226, Beyotime, China).

**FIGURE 1** | Phylogenetic relationships of A. simiae A6 with all other Aeromonas species inferred on the (A) MLPA tree and (B) whole-genome-based phylogeny tree. Nodes supported with bootstrap values over 50% are marked by gray dots. A. simiae A6 is indicated with a red dot.
Determination of Kinetic Parameters

Kinetic parameters for hydrolysis of β-lactams by the purified OXA-830 β-lactamase were examined using a UV-VIS spectrophotometer (U-3900, HITACHI, Japan) at 30°C in 10 mM phosphate buffer (pH 7.0) in a final reaction volume of 300 µL. The steady-state kinetic parameters (kcat and KM) were determined by non-linear regression of the initial reaction rates with the Michaelis–Menten equation in Prism (version 7) software (GraphPad Software, San Jose, CA, United States).

β-lactamase inhibition was studied with benzylpenicillin (500 µM) as the substrate. The β-lactamase inhibitors sulbactam, tazobactam and clavulanic acid at various concentrations were preincubated with the purified OXA-830 β-lactamase for 3 min at 30°C before addition of substrate. The inhibitor concentration required to reduce the hydrolysis of 500 µM benzylpenicillin by 50% was determined by non-linear regression with the log(inhibitor) vs. response – Variable slope equation in Prism (version 7) software (GraphPad Software, San Jose, CA, United States).

Nucleotide Sequence Accession Number

The complete nucleotide sequences of the chromosome of A. simiae A6 and the blaOXA−830 gene in this work have been submitted to DDBJ/EMBL/GenBank under accession numbers CP040449 and MK926981, respectively.

RESULTS AND DISCUSSION

Identification and Characterization of the OXA-830-Producing Isolate, A. simiae A6

Aeromonas simiae A6 was isolated in 2017 from sewage discharged from a farm in Wenzhou, southern China. A 16S ribosomal RNA gene homology analysis showed that A. simiae A6 had the closest relationship with one A. simiae strain (A. simiae IBS S6874 [NR_025585.1]), at 99% identity and 99% coverage. The MLPA tree and whole-genome-based phylogeny tree congruously showed that A. simiae A6 was phylogenetically closest to A. simiae CIP 107798, which constituted a robust phylogenetic branch with considerable reliability (Figures 1A,B).

We finally grouped the strain into the species A. simiae and named it A. simiae A6.

In vitro susceptibility testing showed that wild-type A. simiae A6 exhibited resistance to ampicillin and ticarcillin (Table 1). Moreover, the MICs of oxacillin, cloxacillin, benzylpenicillin, benzylpenicillin/clavulanic acid and benzylpenicillin/sulbactam against A. simiae A6 were 512, 512, 64, 64, and 32 µg/mL, respectively, which were significantly higher than or equal to the resistance breakpoint for ampicillin (≥32 µg/mL), though no interpretation criteria for these antimicrobials were available.

Since the high MICs of the aforementioned antimicrobials and no complete genome sequence of species A. simiae is available, we performed further study for this isolate.

TABLE 2 | General features of the A. simiae A6 genome.

| Feature                        | Value                  |
|--------------------------------|------------------------|
| Size (bp)                      | 3,974,097              |
| GC content (%)                 | 60.56                  |
| Predicted coding sequences (CDSs) | 3,633                 |
| Known proteins                 | 3,149 (86.7%)          |
| Hypothetical proteins          | 484 (13.3%)            |
| Protein coding (%)             | 87.41%                 |
| Average ORF length (bp)        | 956                    |
| Average protein length (aa)    | 317                    |
| rRNA operons                   | (16S-23S-5S)*9         |
| tRNAs                          | 16S-23S-5S-5S          |
|                                    | 126                    |
Currently available in the public database, the complete genome of *A. simiae* A6 was determined to unveil the potential factors associated with the resistance profiles. The results showed that *A. simiae* A6 has a circular chromosome (without plasmids) of 3.97 Mb in size that contains 3,633 ORFs with an average GC content of 60.56% (Table 2 and Figure 2). Comparative genomics analysis revealed the genome of *A. simiae* A6 shared the highest sequence similarities with that of *A. schubertii* WL1483 (accession number CP013067, at 91.62% identity and 65% coverage) and *A. schubertii* LF1708 (accession number CP039611, at 91.56% identity and 65% coverage) (Figure 2). Notably, *A. simiae* A6 encodes two predicted DBL-encoding genes. One is bla\(_{OXA-10}\) located in a truncated class I integron with a gene array of intI1-qnrVC4-cmlA5-bla\(_{OXA-10}\)-aac(6')-Ib-cr-aaA14-dfrA14-mobC-IS6100 (ranging from 3261 to 3269 kb), and the other belongs to a novel OXA β-lactamase named OXA-830.
**Possible Origin of the New Class D β-Lactamase OXA-830**

*bla* _OXA–830_ gene was 801 bp in length and encoded a 266 amino acid preprotein of ca. 29.4 kDa. A signal peptide cleavage site was predicted to be between an alanine and asparagine at amino acid residues 22 and 23. In addition, the pI value of OXA-830 was predicted to be 9.18. The closest relative of OXA-830 was OXA-725, a class D β-lactamase with detectable hydrolytic activity against oxacillin, penicillin and ampicillin as well as carbenicillin, which was previously described in a clinical *A. jandaei* (formerly *A. sobria*) isolate from the Hammersmith Hospital, London (Walsh et al., 1995). Screening for *bla* _OXA–830_-homologous genes (≥70% amino acid sequence identity) in the NCBI nucleotide database showed that most of the close relatives (89.1%, 66/74) were derived from the genus *Aeromonas*, except 4 genes from *Enterobacteriaceae* and 4 of undetermined origin, suggesting the importance of *Aeromonas* as the reservoir for *bla* _OXA–830_-like genes. Additionally, OXA-830 was distantly related to other class D β-lactamases in amino acid sequence identity, i.e., OXA-12 and its close variants (77.1% with OXA-12; 78.9% with OXA-726; and 78.6% with OXA-724). Moreover, it shared identities of respective 72.2, 71.1, and 70.7% with OXA-427, OXA-780, and OXA-504 (Figure 3), and possessed less than 50% identities to all of the other DBLs.

Four conserved motifs were identified from OXA-830 and other OXA family DBLs: serine-threonine-phenylalanine-lysine (S-T-F-K) at positions 70 to 73, tyrosine-glycine-asparagine (Y-G-N) at positions 144 to 146, Q-X-X-X-L at positions 176 to 180, and lysine-threonine-glycine (K-T-G) at positions 216 to 218 (DBL numbering). However, the conserved S-X-V motif at residues 118 to 120 (DBL numbering), one of the active sites of DBLs (Paetzol et al., 2000), was found to be slightly different in OXA-427, OXA-780, and OXA-504, whose valine at residue 120 was replaced by isoleucine. In addition, OXA-830 possessed as many as 40 unique amino acid differences compared to all the other DBLs.
other DBLs (Figure 3). A phylogenetic tree containing OXA-830 and other DBLs (>41% amino acid identity) (Figure 4) was constructed and the results showed that OXA-830 clustered closest to OXA-12, OXA-725, OXA-726, and OXA724. Thus, OXA-830 represents a novel lineage of DBLs.

**Genetic Context of bla<sub>OXA-830</sub> Gene**

A comparative genomics analysis of the genetic environment of the bla<sub>OXA-830</sub> gene in A6 with that of closely related DBL-encoding genes in three other Aeromonas strains showed that glmU (encoding the bifunctional protein GlmU) together with upstream sequences shared a conserved syntenic architecture in gene content and gene order (Figure 5). However, the genes downstream of glmU in the bla<sub>OXA-830</sub>-related region were highly distant to those of all the other bla<sub>OXA</sub> genes. In fact, the region from bla<sub>OXA-830</sub> to a large hypothetical gene in the bla<sub>OXA-830</sub>-related region was flanked by a pair of perfect 9-bp inverted repeats (IRs), suggesting these genes might be transferred from the other strain through horizontal gene transfer. Furthermore, an approximately 25-kb genomic island including two phase integrase-encoding genes was found upstream of the large hypothetical gene, which was enwrapped by a pair of perfect 10-bp direct repeats (DRs). This indicated that the mobilization of this genomic island onto the genome of A6 might have resulted from the integrase-mediated site-specific recombination. Altogether, these potential lateral gene transfer events may well explain the discrepancy of gene content between the bla<sub>OXA-830</sub>-related region and other bla<sub>OXA</sub>-related regions.

**Functional Characterization of the OXA-830 β-Lactamase**

The cloned bla<sub>OXA-830</sub> gene in E. coli DH5α recombinant clones (pUCP24-bla<sub>OXA-830</sub>/DH5α) conferred resistance to all the penicillins and β-lactamase inhibitors examined in this study except for benzylpenicillin/sulbactam (Table 1). More specifically, it facilitated different increases in MIC levels for ampicillin (128-fold), ampicillin/sulbactam (8-fold), oxacillin (>4-fold), cloxacillin (>4-fold), benzylpenicillin (32-fold), benzylpenicillin/tazobactam (8-fold), benzylpenicillin/clavulanic acid (8-fold), ticarcillin (512-fold), ticarcillin/clavulanic acid (128-fold), piperacillin (256-fold) and piperacillin/tazobactam (4-fold) compared with those of the control strain (pUCP24/DH5α), although the MICs against ampicillin, benzylpenicillin, ticarcillin, and piperacillin were decreased in the presence of inhibitors. In addition, OXA-830 did not confer resistance to cephalosporins, aztreonam or carbapenems (Table 1).

The kinetic parameters of the OXA-830 β-lactamase purified from the extract of E. coli BL21 harboring the recombinant plasmid pET-OXA-830 demonstrated that OXA-830 had a strong hydrolytic activity against penicillins (including oxacillin, cloxacillin, benzylpenicillin, ampicillin, piperacillin, and ticarcillin) and cefazolin \( k_{cat}/K_m \) ratios were greater than 0.73 \( \mu \text{M}^{-1} \cdot \text{s}^{-1} \), while very poor hydrolytic activities were detected for cefotaxim and ceftazidime. Moreover, no measurable hydrolytic activities were observed for cefepime, aztreonam and imipenem (Table 3). Nevertheless, this finding was not entirely consistent with the above MIC changes for E. coli DH5α recombinant clones (pUCP24-bla<sub>OXA-830</sub>/DH5α) in the antibiotic susceptibility assay, as the hydrolytic activities against cefazolin, cefotaxim and ceftazidime did not result in significant changes in the MICs for E. coli DH5α recombinant clones. It may be that the activity in vitro was simply too low to contribute to activity in vivo. A similar phenomenon was observed from OXA-436 which showed hydrolytic activity against ceftazidime but not confer resistance to ceftazidime (Samuelsen et al., 2018). OXA-830 exhibited an approximately 2-fold increase in the turnover rate \( k_{cat} \) for oxacillin and cloxacillin compared to that for benzylpenicillin. The highest catalytic efficiency was observed with ampicillin \( k_{cat}/K_m \) ratio was 2.36 \( \mu \text{M}^{-1} \cdot \text{s}^{-1} \). Of note, the catalytic efficiencies of OXA-830 against oxacillin and ampicillin matched or surpassed those of several clinically important DBLs in Gram-negative pathogens, such as OXA-48 and OXA-58 (Docquier et al., 2009; Verma et al., 2011). Compared to OXA-12 (Rasmussen et al., 1994), OXA-830 exhibited significantly lower affinity for penicillins used in both studies. Although susceptible to cephalosporins, the extended hydrolysis spectrum of OXA-830 indicated that it could be exceptionally classified into subgroup 2de, a new subgroup of DBLs including the oxacinil- or cloxacillin-hydrolyzing β-lactamases exhibiting hydrolytic activity against oxymino-cephalosporins but not carbapenems (Bush and Jacoby, 2010). Interestingly, most of the members of this subgroup originated from OXA-10, with a small number of amino acid substitutions described as previously
However, OXA-830 exhibited only 22.6% global amino acid identity with OXA-10. In contrast, OXA-830 shared much higher global amino acid identity (72.2%) with OXA-427, which could hydrolyze imipenem and exhibit resistance to extended-spectrum cephalosporins (mostly ceftazidime) (Bogaerts et al., 2017).

The results of β-lactamase activity inhibition measurement, as measured by IC\textsubscript{50} (50% inhibitory concentrations), showed that OXA-830 was strongly inhibited by sulbactam (IC\textsubscript{50}: 0.05 ± 0.01 μM) and tazobactam (IC\textsubscript{50}: 0.07 ± 0.02 μM), and was less sensitive to clavulanic acid (IC\textsubscript{50}: 0.26 ± 0.02 μM), which could explain the above MIC changes of β-lactams with or without β-lactamase inhibitors. However, this finding was inconsistent with what was found for OXA-12 (Rasmussen et al., 1994), which was strongly inhibited by clavulanic acid (IC\textsubscript{50}: 0.009 μM) and tazobactam (IC\textsubscript{50}: 0.03 μM), and less effectively inhibited by sulbactam (IC\textsubscript{50}: 0.24 μM).

CONCLUSION

The complete genome sequence of \textit{A. simiae} was firstly reported in this work. We identified a novel OXA DBL named OXA-830 that was encoded on the chromosome of \textit{A. simiae} A6. The new enzyme exhibited high amino acid sequence divergence from all currently available DBLs and showed the top amino acid identities (77.1–79.3%) with OXA-12 and OXA-12-like β-lactamases. Therefore, OXA-830 could be characterized as the...
first member of a new lineage of DBLs. OXA-830 showed some common functional properties with other OXA β-lactamases such as OXA-12, but significant differences were also observed. It possessed extended-spectrum hydrolytic properties which was strongly inhibited by both sublactam and tazobactam. These findings revealed the importance of OXA-830 as a new model to study the structure/function relationships among OXA β-lactamases. Paired terminal IRs at both ends of the bla\textsubscript{OXA−830} related region suggested that the possibility of dissemination of bla\textsubscript{OXA−830} in the environment is still existent, although it is not associated with any known MGE.

**DATA AVAILABILITY STATEMENT**

The datasets generated for this study can be found in the GenBank database as GenBank: CP040449 for the A. simiae A6 genome sequence, GenBank: MK926981 for the OXA-830 gene.

**AUTHOR CONTRIBUTIONS**

QC, KS, XZ, DZ, HL, WL, and KL collected the strains and performed the experiments. WZ, QC, and TX performed the experimental results. WZ, QC, and TX performed the bioinformatics analysis. WZ, JL, and QB co-led the writing of the manuscript. JL and QB designed the work. All authors read and approved the final version of the manuscript.
