ABSTRACT

Background: Spinal synovial cysts, attributed to degenerative changes of the facet joints, commonly occur at the sites of segmental spinal instability. Here, we present a patient with diffuse idiopathic skeletal hyperostosis (DISH) who developed a T10/T11 synovial cyst contributing to myelopathy that resolved following surgical cyst excision.

Case Description: A 69-year-old male presented with progressive numbness and paraparesis for 2-month duration. The thoracic MR spine showed synovial cyst at the T10/T11 level, while the computed tomography confirmed DISH fusion between the T4 and T10 levels. Following a laminectomy with cyst excision, the patient's symptoms resolved and he sustained no recurrent dynamic instability.

Conclusion: A patient with DISH presented with the new onset of myelopathy attributed to a T10/T11 thoracic synovial cyst; following cyst excision, the patient's myelopathy resolved.

Keywords: Diffuse idiopathic skeletal hyperostosis, Instability, Synovial cyst, Thoracic spine

INTRODUCTION

Synovial cysts of the spine may be simple fluid-filled sacs or thick, fibrinous, touch, and tenacious lesions arising from the facet joints. They rarely occur in thoracic spine (i.e., 1.6% incidence reported).[3] They are most likely due to degenerative changes and/or mechanical instability impacting the dorsal overlying facet joints.[2,8] Diffuse idiopathic skeletal hyperostosis (DISH) results in spontaneous bony bridging of the anterolateral spinal ligaments and tendons.[10] Here, we report a 69-year-old male with T4–10 spontaneous anterior DISH fusion who developed myelopathy due to a T10/T11 synovial cyst extrusion; following removal of the cyst, the patient's symptoms resolved.

CASE DESCRIPTION

History and imaging findings

A 69-year-old male patient presented with a progressive paraparesis of 2-month duration. On presentation, he showed predominantly a right paraparesis, brisk patellar tendon reflexes, diminished sensation in the lower limbs to both pinprick and vibration, and a spinal sensory
level at T10 but intact sphincter function. The thoracic MR showed central canal stenosis through the T10–12 levels and a dorsal extradural cyst at the T10/11 level that enhanced with contrast and contributed to cord compression [Figures 1a-d]. The computed tomography additionally demonstrated bridging anterior DISH ossification from T4 to T10 [Figures 2a and b]. A vacuum phenomenon was noted in T10/11 adjacent facet joint [Figure 2c].

Surgery and histology

He underwent T9-T12 partial and T10–11 total laminectomy with resection of the cystic lesion. The dorsal adherent cystic structure contiguous to the right facet was completely removed. Histopathological examination showed cystic formation with granulation tissue, calcification, inflammatory cells, and chondroid metaplasia, compatible with synovial cyst.

Postoperative course

The patient sustained no perioperative/postoperative complications and the postoperative imaging studies showed decompression of spinal cord with no residual cyst [Figure 3]. At the 3-postoperative month follow-up, he had recovered significant motor and sensory function in both lower extremities, sufficient to walk independently [Table 1].

Figure 1: Magnetic resonance imaging (MRI) of the thoracic spine. (a) Sagittal T2-weighted image shows central canal stenosis at Th10/11, Th11/12. (b) Axial T2-weighted image reveal dorsal extradural cystic lesion and fluid within the right facet joint at Th10/11. (c) Axial T1-weighted image shows dorsal hypointense lesion. (d) Gadolinium-enhanced T1-weighted MRI showed peripherally enhancing mass in the extradural space.

Figure 2: Computed tomography scan images of the whole spine. (a) Sagittal view shows horizontally oriented ossification of anterior longitudinal ligament in thoracic spine and gas-containing disc at multiple levels. (b) 3D reconstruction image reveals bridging of vertebral bodies from Th4 to Th10. (c) Axial image shows gas within Th10/11 facet joint.
CONCLUSION

A 69-year-old male with T4–10 DISH developed myelopathy attributed to a right-sided T10/T11 synovial cyst extrusion just below the fused thoracic vertebrae that resolved following cyst excision.
