Inequities in postnatal care in low- and middle-income countries: a systematic review and meta-analysis
Étienne V Langlois, a Malgorzata Miszkurka, b Maria Victoria Zunzunegui, b Abdul Ghaffar, c Daniela Ziegler d & Igor Karp d

Objective To assess the socioeconomic, geographical and demographic inequities in the use of postnatal health-care services in low- and middle-income countries.

Methods We searched Medline, Embase and Cochrane Central databases and grey literature for experimental, quasi-experimental and observational studies that had been conducted in low- and middle-income countries. We summarized the relevant studies qualitatively and performed meta-analyses of the use of postnatal care services according to selected indicators of socioeconomic status and residence in an urban or rural setting.

Findings A total of 36 studies were included in the narrative synthesis and 10 of them were used for the meta-analyses. Compared with women in the lowest quintile of socioeconomic status, the pooled odds ratios for use of postnatal care by women in the second, third, fourth and fifth quintiles were: 1.14 (95% confidence interval, CI: 0.96–1.34), 1.32 (95% CI: 1.12–1.55), 1.60 (95% CI: 1.30–1.98) and 2.27 (95% CI: 1.75–2.93) respectively. Compared to women living in rural settings, the pooled odds ratio for the use of postnatal care by women living in urban settings was 1.36 (95% CI: 1.01–1.81). A qualitative assessment of the relevant published data also indicated that use of postnatal care services increased with increasing level of education.

Conclusion In low- and middle-income countries, use of postnatal care services remains highly inequitable and varies markedly with socioeconomic status and between urban and rural residents.

Introduction
Each year an estimated 289 000 women die worldwide from complications related to pregnancy, childbirth or the postnatal period and up to two thirds of such maternal deaths occur after delivery. Poor outcomes of maternal and neonatal care also include 2.9 million neonatal deaths per year. Of the maternal and neonatal deaths that occur globally, 99% occur in low- and middle-income countries.

According to the World Health Organization (WHO), the postnatal period begins immediately after childbirth and lasts six weeks. In low-income countries, almost 40% of women experience complications after delivery and an estimated 15% develop potentially life-threatening problems. Postnatal care services are a fundamental element of the continuum of essential obstetric care — which also includes antenatal care and skilled birth attendance — that decreases maternal and neonatal morbidity and mortality in low- and middle-income countries.

Compared with other maternal and infant health services, coverage for postnatal care tends to be relatively poor. Increasing such coverage has been highlighted as a priority. In the Democratic Republic of the Congo, for example, at least 93% of pregnant women receive antenatal care and skilled birth attendance but only 35% of births receive postnatal care. In Kenya, fewer than 20% of women use postnatal care services. In 2014, WHO recommended that a mother and her newborn child should receive postnatal care within 24 hours of the birth and then at least three more times — i.e. at least on day three after the birth, in the second week after the birth and six weeks after the birth. Postnatal care services can be defined as preventive care practices and assessments that are designed to identify and manage or refer complications for both the mother and the neonate. Typically, such services include an integrated package of routine maternal and neonatal care as well as extra care for neonates that are considered particularly vulnerable because, for example, they are preterm, have a low birth weight, are small for gestational age or have mothers infected with human immunodeficiency virus (HIV).

Possible postnatal interventions for the mother include: (i) iron and folic acid supplementation for at least three months; (ii) screening for — and treatment of — infection, haemorrhage, thromboembolism, postnatal depression and other conditions; (iii) prophylactic antibiotics given to women who have a third- or fourth-degree perineal tear; and (iv) counselling on early and exclusive breastfeeding, nutrition, birth spacing and family planning options — including any available contraception. Possible interventions for the neonate include: (i) care of the umbilical cord; (ii) special care for preterm, low-birth-weight and HIV-infected neonates; (iii) screening and treatment of infections and postnatal growth restriction; (iv) assessment of factors predisposing to infant anaemia; and (v) teaching the mother to seek additional care for her neonate if she notices danger signs such as convulsions or problems with feeding.

Low use of postnatal care services is associated with lack of education, poverty and limited access to health-care facilities. However, these associations have not been assessed systematically. We therefore conducted a systematic review...
of the relevant evidence from low- and middle-income countries, to inform policy-making, help strengthen health systems and increase access to – and use of – postnatal care services.

Methods

We followed guidelines for systematic reviews from the Cochrane Collaboration and a standardized methodology described in an explicit protocol. The review was registered with the Prospero database (registration number: CRD42013004661) and results were reported according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement.

Literature search

To identify the studies of interest, we searched the Medline, Embase and Cochrane Central databases and grey literature for relevant medical subject headings and keywords. We focused on articles published between 1 January 1960 and 31 May 2013 in English, French, Spanish, Portuguese and Chinese and were assisted by an expert librarian. Our search strategy combined terms related to postnatal or postpartum care, use or accessibility, determinants or inequities and low- or middle-income countries. Our full search strategy is detailed in Appendix A (available at: https://dl.dropboxusercontent.com/u/28446882/Appendix%20A.pdf).

To identify further data that might be useful, we also checked the reference lists of the articles found to be of potential interest, visited institutional web sites and contacted the authors of some of the articles of interest and other experts in the field.

Inclusion criteria

We retrieved data from experimental, quasi-experimental and observational studies of women aged 15–49 years, that had been implemented in low- or middle-income countries as defined by the World Bank. The primary outcome of interest was the use of postnatal care services – i.e. at least one follow-up visit in the 42 days post-childbirth. We included studies in which the potential socioeconomic, geographical and/or demographic determinants of the use of postnatal care had been assessed. The potential socioeconomic determinants that we investigated were socioeconomic status, occupation and education. We investigated distance and travel time to a health centre and place of residence – i.e. urban or rural – as potential geographical determinants and ethnicity, marital status, religion and immigration status as potential demographic determinants. We analysed data from studies that included at least one association measure – such as a frequency ratio or difference – or the result of at least one statistical test in which use of postnatal care had been compared across two or more categories.

We included relative comparisons to a reference group (e.g. concentration indexes) and absolute comparisons (e.g. slope indexes of inequality). In some relevant studies, a concentration index

Notes: In each study, women were assigned to one of five socioeconomic status quintiles, from the highest (Q5) to the lowest (Q1). Each odds ratio is an estimate for a comparison between the women in Q2 and those in Q1, with the latter used as the reference category.

was used to measure the relationship between accumulated proportions of mothers ranked by their socioeconomic status against the cumulative proportion of postnatal care use. In these studies, a positive value for the index indicates that rich households have greater coverage than poor households, a negative index indicates that poor households have greater coverage than rich households and zero values for the index that coverage is independent of socioeconomic status. Other studies used a slope index of inequality to estimate the absolute difference in percentage postnatal care coverage between individuals at the top and bottom of the socioeconomic status scale. In such studies, a high slope index of inequality would have indicated great inequity in coverage.

**Data extraction**

The eligibility of each study identified in the initial screening was assessed by two reviewers using a standardized form with explicit inclusion and exclusion criteria. There was a high level of agreement between the reviewers (Cohen’s kappa, $\kappa = 0.92$). Data were extracted with a standardized data collection form that had been pilot tested on a random sample of studies. We collected data on country, setting, year of publication, study design, sample size, population attributes, outcome definition, comparison groups, point estimates and precision measures.

**Quality assessment**

Two individuals, working independently, assessed the scientific quality of each selected study using the Effective Public Health Practice Project’s quality assessment tool for quantitative studies – after extending the criteria for selection bias assessment. Scientific quality was categorized as high, moderate or low if, respectively, the risk of bias in the study results was considered to be very low, low or high. The level of agreement between the two assessors of quality was good ($\kappa = 0.75$). Discrepancies in the assessment of eligibility or scientific quality were resolved in discussions with an experienced researcher.

**Data synthesis**

Evidence tables were generated to summarize the selected studies and results descriptively. We conducted a qualitative synthesis of the findings. We also conducted a meta-analysis of selected...
studies that provided a comparable classification of the outcome and determinants of interest. For this purpose, we also required either estimates of the standard errors for the association measure or confidence intervals that allowed us to derive such estimates. Many of the studies included in the systematic review had to be excluded from the meta-analysis because of differences in the classification or definition of determinants. We pooled the association measures for socioeconomic status and geography, as represented by socioeconomic status quintile and an indicator of urban/rural place of residence, respectively. We assessed heterogeneity of these results using Cochran’s Q test and the P statistic. We used random-effects meta-analysis models when heterogeneity was statistically significant (P > 0.1) and P was moderate or high according to the criteria of Higgins et al. We conducted sensitivity analyses by removing studies deemed to be of low quality or potential outliers. We assessed publication bias in the meta-analyses with funnel plots. Data analysis was performed using Stata version 12.0 (StataCorp LP, College Station, United States of America).

Results

Our initial search produced 3152 articles of potential interest and articles describing 36 studies contributed to our qualitative synthesis of evidence (Fig. 1). Data from 10 of the studies were included in the meta-analysis. The 36 studies included in our qualitative synthesis of evidence comprised two randomized controlled trials, three quasi-experimental studies, two cohort and 28 cross-sectional studies, and one investigation of 31 demographic and health surveys. Of these 36 studies, 11 were conducted in low-income countries, 24 in middle-income countries and one in both low- and middle-income countries. Three, 26 and six of the 36 studies were deemed to be of high, moderate and low scientific quality, respectively. A lack of information on methodology prevented the assessment of the scientific quality of one study included in the qualitative synthesis (Table 1, available at: http://www.who.int/bulletin/volumes/93/4/14-140996).

Socioeconomic determinants

Socioeconomic status

Our qualitative assessment of relevant studies indicates that there was a gradient in the use of postnatal care according to socioeconomic status – as measured on different scales (Table 2, available at: http://www.who.int/bulletin/volumes/93/4/14-140996). Results of our meta-analysis that included data on socioeconomic status from studies of moderate quality also indicated that the higher the socioeconomic status of the mother, the more likely she was to access postnatal care (Fig. 2, Fig. 3, Fig. 4 and Fig. 5).

Meta-analysis was used to derive pooled adjusted odds ratios (OR) from 10 studies and a total of 136 431 women. For each quintile of socioeconomic status, the Q test gave a significant result and the F statistic fell between 50% and 75% – indicating moderate heterogeneity. When the lowest quintile (Q1) was used as the reference, the pooled OR for the highest quintile (Q5) was 2.27 (95% confidence interval, CI: 1.75–2.93). The

Table 3. Socioeconomic inequities in postnatal care coverage

DHS: Demographic and Health Survey.

Data source: adapted from Countdown to 2015. Maternal, newborn & child survival. Building a future for women and children. The 2012 report.
### Table 4. Geographical determinants for the use of postnatal care services in low- and middle-income countries

| Study                  | Adjusted | Comparison groups                                                                 | Odds ratio* |
|------------------------|----------|------------------------------------------------------------------------------------|-------------|
| Abbas and Walker (1986) | No       | Place of residence categorized as urban or rural, with rural used as reference      | Estimated – for the non-use of PNC – as 1.40 |
| Agha (2011)            | Yes      | Travel time to nearest health facility, categorized as no more than 5 minutes or more than 5 minutes, with the longer time used as reference | 1.81 (P < 0.001) |
| Agha and Carton (2011)  | Yes      | Travel time to nearest health facility, categorized as no more than 15 minutes or more than 15 minutes, with the longer time used as reference | 1.13 (NS) |
| Anson (2004)           | Yes      | Distance to county hospital                                                        | 0.99 (P < 0.01) |
| Anwar et al. (2008)    | Yes      | Distance to hospital, categorized as more than 5 km or 0–5 km, with 0–5 km used as reference | 1.21 (95% CI: 0.98–1.50) |
| Babalola and Fatusi (2009) | Yes  | Place of residence categorized as urban or rural, with rural used as reference      | 1.63 (P < 0.01) |
| Chakraborty et al. (2002) | Yes  | Distance to health facility, categorized as at least 1 km or less than 1 km, with less than 1 km used as reference | Estimated for care provided by doctor, nurse or family welfare visitor (0.659; 95% CI: 0.277–1.567) and care provided by other individual (1.11; 95% CI: 0.744–1.658) |
| Chatterjee and Paily (2011) | No    | Place of residence categorized as urban or rural, with rural used as reference      | 3.83 |
| Halder et al. (2007)   | Yes      | Place of residence categorized as urban or rural, with rural used as reference      | 1.176 (NS) |
| Jat et al. (2011)      | Yes      | Place of residence categorized as urban or rural, with rural used as reference      | 0.94 (95% CI: 0.78–1.11) |
| Liu et al. (2011)      | Yes      | Altitude of residence above sea level, with no more than 500 m used as reference   | Estimated for 501–1500 (0.49; 95% CI: 0.25–0.97) and more than 1500 m (0.54; 95% CI: 0.30–0.98) |
| Mistry et al. (2009)   | Yes      | Distance to health facility, with less than 2 km used as reference                 | Estimated for 2–5 (0.80; 95% CI: 0.67–0.95) and at least 6 km (0.64; 95% CI: 0.50–0.83) |
| Mullany et al. (2008)  | No       | Forced displacement or relocation in prior 12 months or otherwise, with otherwise used as reference | 0.40 (95% CI: 0.13–1.28) |
| Okafor (1991)          | Yes      | Distance from service                                                              | 0.99 (P < 0.01) |
| Rahman et al. (2011)   | Yes      | Place of residence, categorized as urban or rural, with urban used as reference     | Estimated as 0.77 (95% CI: 0.53–0.84) in a comparison of skilled PNC versus unskilled or no such care and as 0.52 (95% CI: 0.42–0.63) in a comparison of PNC on 1 or 2 days with more days of PNC |
| Rai et al. (2012)      | Yes      | Place of residence categorized as urban or rural, with rural used as reference      | 1.212 (95% CI: 0.861–1.706) |
| Ram and Singh (2006)   | Yes      | Distance to transport facility, categorized as 0–2 km or more than 2 km, with the longer distance used as reference | 0.947 (NS) |
| Sarma and Rempel (2007) | Yes    | Distance to health facility, with less than 2 km used as reference                 | Estimated for 2–5 (0.777; P < 0.01), 5–10 (0.746; P < 0.01) and more than 10 km (0.751; P < 0.01) |
| Sharma et al. (2007)   | Yes      | Place of residence categorized as urban or rural, with rural used as reference      | 1.178 (P < 0.01) |
| Singh et al. (2012)    | Yes      | Region of residence, with south used as reference                                  | Estimated for north (0.219; 95% CI: 0.165–0.291), central (0.089; 95% CI: 0.070–0.113), east (0.157; 95% CI: 0.127–0.193), north-east (0.068; 95% CI: 0.043–0.107) and west regions (0.308; 95% CI: 0.238–0.400) |
| Stupp et al. (1994)    | Yes      | Place of residence categorized as rural or not rural, with not rural used as reference | 0.83 (NS) |
| Tailley et al. (2009)  | ND       | Place of residence, categorized as urban or rural, with urban used as reference     | Estimated – for non-use of PNC – as 2.00 (95% CI: 1.54–2.60) |

* a Unless another association measure is indicated. Odds ratios were estimated for the use of postnatal care services unless indicated otherwise.
corresponding OR for Q4, Q3 and Q2 were lower, at 1.60 (95% CI: 1.30–1.98; \(F\): 70%), 1.32 (95% CI: 1.12–1.55; \(F\): 50%) and 1.14 (95% CI: 0.96–1.34; \(F\): 52%), respectively.

In a sensitivity analysis, we removed the potentially atypical data reported by Amin et al.\(^{33}\) The pooled OR for Q5, Q4, Q3 and Q2 – with Q1 used as the reference – were reduced to 2.09 (95% CI: 1.70–2.56), 1.55 (95% CI: 1.27–1.90), 1.30 (95% CI: 1.10–1.54) and 1.08 (95% CI: 0.95–1.24), respectively.

The data in a report\(^ {15}\) included in the systematic review showed concentration index and slope index of inequality for use of postnatal care in 31 countries (Table 3). For the low-income countries, the mean concentration index was 0.23 and the mean slope index of inequality was 53%. The corresponding values for the middle-income countries were 0.18 and 61%, respectively. In Pakistan, exposure to a voucher scheme led to significant increase in the use of postnatal care (OR: 4.98; \(P < 0.001\)).\(^ {30}\)

**Level of education**

Our qualitative assessment of studies indicated marked variations in the use of postnatal care according to the level of education of the women investigated – or their partners (Table 2). Compared to women who had received no formal education, women who had attended primary education were more likely to use postnatal care\(^ {16,17,38,40,50,60}\) and women who had completed secondary school were the most likely to access postnatal care.\(^ {2,7,13,15,16,17,38,48,49,51}\) In three studies, the duration of maternal schooling was found to be positively correlated with postnatal care use.\(^ {33,41,46}\) Compared with other women, those with husbands who had completed secondary school also appeared more likely to use postnatal care.\(^ {16,41,46}\) In Lebanon, an educational intervention to emphasize the importance of postnatal care led to a marked increase in the use of such care (relative risk: 2.8; 95% CI: 2.2–3.4).\(^ {27}\) Inconsistent classification of education status prevented us from performing a meta-analysis of these apparent determinants of the use of postnatal care.

**Occupation**

The income-earning occupations of women and their husbands appear to influence the women’s use of postnatal care (Table 2). For example, women married to men with professional, technical or managerial occupations were more likely to use postnatal care than women married to manual labourers (OR: 2.22; 95% CI: 1.62–2.81).\(^ {37}\) Similarly, women married to men with well paid jobs were more likely to use postnatal care than women married to farmers (OR: 1.45; \(P = 0.05\)).\(^ {39}\) In China, women with so-called white-collar occupations were more likely to use postnatal care than other women (OR: 2.17; \(P < 0.001\)).\(^ {33}\) Inconsistent classification of occupation impeded any corresponding meta-analysis.

**Geographical determinants**

A qualitative assessment of the evidence indicated that postnatal care was more commonly used by women living in urban areas than by their rural counterparts (Table 4).\(^ {2,7,13,15,16,17,38,48,49,60}\) Our meta-analysis of this trend was based on five studies and a total of 46 913 women.\(^ {2,7,13,15,16,17,38,48,49,60}\) As a Q test gave a significant result (\(P < 0.001\)) and \(I^2\) was 83.7%, heterogeneity was considered high.\(^ {27}\) With women in rural areas used as the reference, our initial estimate of the pooled OR for use of postnatal care by women residing in urban areas was 1.36 (95% CI: 1.01–1.81; Fig 6). After removing the study deemed to be of low quality,\(^ {38}\) the estimated pooled OR became 1.21 (95% CI: 0.95–1.53). In several studies included in our systematic review, distance to the nearest health facility was also found to be associated with use of postnatal care services. In India, for example, the relevant OR for distances of 2–5 and at least 6 km – with a distance of less than 2 km used as the reference – were 0.80 (95% CI: 0.67–0.95) and 0.64 (95% CI: 0.50–0.83), respectively.\(^ {44}\) In rural areas of India, the presence of a bus service has been found to increase the use of postnatal care services (OR: 1.18; \(P < 0.01\)).\(^ {48}\)

**Demographic determinants**

**Religion**

In one study, use of postnatal care services was higher among Muslim women than among Christian women (OR: 2.01; 95% CI: 1.24–3.25).\(^ {38}\) In contrast, in another study, Muslim women seemed less likely to use such services than their non-Muslim counterparts (OR: 0.77; 95% CI: 0.61–1.34).\(^ {34}\) In Nepal, compared with Hindu women, Buddhist women were less likely to use postnatal care services (OR: 0.25; \(P < 0.001\)).\(^ {48}\) Overall, our systematic review of relevant studies revealed no clear trend in the use of such services according to religion (Table 5).

**Ethnicity**

In India, women belonging to the lower social groups – i.e. those belonging to scheduled castes (OR: 0.69; 95% CI: 0.55–0.86), scheduled tribes (OR: 0.71; 95% CI: 0.54–0.91) or other so-called backward classes (OR: 0.58; 95% CI: 0.48–0.71) – were found to be less likely to use postnatal care services than those belonging to upper castes (Table 5).\(^ {41}\) Although we found statistically significant differences in the use of postnatal care services according to the ethnicity of the women investigated, our systematic review revealed no clear trend in the use of such services according to whether the woman involved belonged to a minority or majority group.\(^ {11,13,30,43,31,32,39}\)

**Discussion**

We have systematically reviewed studies assessing inequities in the use of postnatal care services in low- and middle-income countries. We found
Table 5. Demographical determinants for the use of postnatal care services in low- and middle-income countries

| Study                        | Adjusted | Comparison groups                                                                 | Odds ratio* |

أجرينا بحثاً في قواعد بيانات التعليم في البلدان المنخفضة الدخل والبلدان المتوسطة الدخل (فاصل الثقة: من 1.12 إلى 1.98)، وجدنا أن نسبة الأمهات مهتمات بالرعاية في المناطق الحضرية، حيث كانت نسبة الأمهات المهتمات بالرعاية في المناطق الحضرية 2.27 مرة أعلى من نساء البلدان الريفية. ومقارنة بالنساء اللاتي يعشن في المناطق الريفية، كانت نسبة الاحتمال المجمعة لاستفادة النساء اللاتي يعشن في المناطق الحضرية 2.27 مرة أعلى من نساء البلدان الريفية.

中低收入国家产后护理的不平等: 系统回顾与综合分析

目的 评估中低收入国家在使用产生后卫生保健服务的经济社会学、地理学与人口学方面的不平等现象。

方法 我们搜集了 Medline、Embbase、Cochrane Central 数据库及灰色文献，查找在中低收入国家执行的实验、类实验和观察性研究。我们定性地总结了相关研究，并根据社会经济地位以及城市或农村居住等选定指标进行产后护理服务使用的综合分析。

结果 总共 36 项研究被纳入叙述合成，其中 10 项被用作荟萃分析。与社会经济地位五等分位数最低等的女性相比，排在第二、三、四、五等分位数的女性使用

产后护理的合并优势比分别是：1.14（95% 置信区间，CI：0.96–1.34）、1.32（95% CI：1.12–1.55）、1.60（95% CI：1.30–1.98）和 2.27（95% CI：1.75–2.93）。与居住在农村环境的女性相比，居住在城市的女性使用产后护理的合并优势比是 1.36（95% CI：1.01–1.81）。对相关公布数据的定性评估同样表明，产后护理服务使用的增加与教育程度成正比。

结论 在中低收入国家，产后护理服务的使用依然处于极度不平等的阶段，因社会经济地位与城乡居民间的差异，产后护理的使用也明显不同。

Résumé

Inégalités des soins postnatals dans les pays à revenu faible et à revenu intermédiaire: revue systématique et méta-analyse

Objectif Evaluer les inégalités socio-économiques, géographiques et démographiques en matière d’utilisation des soins de santé postnatals dans les pays à revenu faible et à revenu intermédiaire.

Méthodes Nous avons effectué une recherche bibliographique dans les bases de données Medline, Embase et Cochrane Central, ainsi que dans la littérature grise, pour trouver les études expérimentales, quasi-experimentales et observationnelles qui ont été menées dans les pays à revenu faible et à revenu intermédiaire. Nous avons fait la synthèse qualitative des études pertinentes et effectué des méta-analyses de l’utilisation des services de soins postnatals en fonction des indicateurs choisis pour le statut socio-économique et la résidence dans les zones urbaines ou rurales.

Résultats Un total de 36 études ont été incluses dans la synthèse narrative et 10 d’entre elles ont été utilisées pour les méta-analyses. Par rapport aux femmes du quintile de statut socio-économique le plus bas, les rapports des cotes regroupés pour l’utilisation des soins postnatals par les femmes dans le deuxième, troisième quatrième et cinquième quintiles étaient de: 1,14 (intervalle de confiance à 95%, IC: 0,96-1,34) et 1,32 (IC à 95%: 1,12-1,55) et 1,60 (IC à 95%: 1,30-1,98) et 2,27 (IC à 95%: 1,75-2,93), respectivement. Par rapport aux femmes vivant en zones rurales, le rapport des cotes regroupé pour l’utilisation des soins postnatals par les femmes vivant en zones urbaines était de 1,36 (IC à 95%: 1,01-1,81). Une évaluation qualitative des données publiées pertinentes a également indiqué que l’utilisation des services de soins postnatals augmentait avec l’augmentation du niveau d’éducation.

Conclusion Dans les pays à revenu faible et à revenu intermédiaire, l’utilisation de services de soins postnatals reste très inéquitable et varie manifestement avec le statut socio-économique et entre les résidents urbains et ruraux.
Las desigualdades en la atención posnatal en los países de ingresos bajos y medianos: una revisión sistemática y metaanálisis

Objetivo Evaluar las desigualdades socioeconómicas, geográficas y demográficas en el uso de los servicios de salud de atención posnatal en países de ingresos bajos y medianos.

Métodos Se buscaron estudios experimentales, cuaseperimentales y observacionales que se habían llevado a cabo en países de ingresos bajos y medianos en las bases de datos Medline, Embase y Cochrane Central, así como en la literatura gris. Se resumieron los estudios relevantes cualitativamente y se realizaron metaanálisis sobre el uso de los servicios de atención posnatal según indicadores seleccionados del nivel socioeconómico y residencia en un entorno urbano o rural.

Resultados Se incluyó un total de 36 estudios en la síntesis narrativa, 10 de los cuales se utilizaron para los metaanálisis. En comparación con las mujeres del quintil más bajo del nivel socioeconómico, las razones de posibilidades agrupadas del uso de atención posnatal de las mujeres en el segundo, tercer, cuarto y quinto quintiles fueron: 1,14 (intervalo de confianza del 95 %: 1,06–1,22), 1,32 (IC del 95 %: 1,12–1,55), 1,60 (IC del 95 %: 1,30–1,98) y 2,27 (IC del 95 %: 1,75–2,93), respectivamente.

En comparación con las mujeres que viven en entornos rurales, la razón de posibilidades agrupada del uso de atención posnatal por mujeres que viven en entornos urbanos fue 1,36 (IC del 95 %: 1,01–1,81). Una evaluación cualitativa de los datos relevantes publicados indicó además que el uso de servicios de atención posnatal ha aumentado mediante el aumento del nivel de educación.

Conclusión En los países de ingresos bajos y medianos, el uso de servicios de atención posnatal sigue siendo muy desigual y varía notablemente con el nivel socioeconómico y entre los residentes urbanos y rurales.

Table 1. Characteristics of studies included in the systematic review on the use of postnatal care services in low- and middle-income countries

| Study                  | Country, year | Design                                                                 | n    | Quality* | Setting                                                                                                                                  |
|------------------------|---------------|-------------------------------------------------------------------------|------|----------|------------------------------------------------------------------------------------------------------------------------------------------|
| Abbas and Walker (1986) | Jordan, 1979  | Cross-sectional national population census, with multi-stage random cluster sampling | 1 765 | Low      | At the time of the study, 72% of women in rural areas lived more than 5 km from a maternal and child health clinic. The corresponding values for women in the three main cities and other urban areas were 7% and 10%, respectively. Most women (53%) reported that they had not received any education on pregnancy or child health |
| Abel Ntambue et al. (2012) | Democratic Republic of the Congo, 2010 | Cross-sectional study                                                   | 1 762 | Low      | Study based in the city of Lubumbashi – the administrative centre of Katanga province and the second most populated city in the country. At the time of the study, the city had an estimated population of 1 415 835 and was divided into health-care zones that were mainly urban and where almost all health services were operational and easily accessible |
| Agha (2011)            | Pakistan, 2008–2009 | Quasi-experimental before-and-after study, with no control group. Intervention: voucher scheme for obstetric services | 1 423 | Moderate | Study area was DG Khan city – a small city located in southern Punjab, in one of the poorest districts of Pakistan |
| Agha and Carton (2011) | Pakistan, 2011 | Cross-sectional representative household survey                         | 2 018 | Moderate | At the time of the study, financial barriers to use of maternal health services remained substantial in rural areas of Jhang district, Pakistan. About 38% of women who did not have their last birth in a health facility cited the high cost of care as the reason for not doing so |
| Amin et al. (2010)     | Bangladesh, 2003–2006 | Cross-sectional household survey                                       | 1 212 | Moderate | Study in 128 rural villages in three of the six divisions of Bangladesh: Chittagong, Dhaka and Rajshahi. Study villages were outside the catchment areas of nongovernmental health centres and could be considered remote. None of the villages was served by a health service |
| Anson (2004)           | China, 1996–1999 | Cross-sectional representative household survey                         | 4 273 | Moderate | Survey of 288 villages in the rural northern province of HeBei. At the time of the study, privatization of rural health services and the costs of unauthorized births presented considerable barriers to the use of maternal care services. The share of public funding for maternal health services had declined considerably and this had led to increases in out-of-pocket expenditure |
| Anwar et al. (2008)    | Bangladesh, 2006 | Cross-sectional community survey                                        | 2 164 | Moderate | Survey in rural and periurban areas. The mean distance between home and the nearest government hospital was 6.2 km. Government services were provided free of charge |
| Babalola and Fatusi (2009) | Nigeria, 2000–2005 | Cross-sectional nationally representative household survey in 36 states | 2 148 | Moderate | Nigeria’s maternal mortality ratio is higher than the regional average and there is wide regional disparity in health status among Nigeria’s diverse and multi-ethnic settings |
| Baqui et al. (2008)    | India, 2001–2005 | Quasi-experimental clustered before-and-after study with control group. Intervention: community nutrition and health government programme facilitated by CARE-India | 14 952 | Moderate | Study in two districts of rural Uttar Pradesh – India’s largest state and one of the most disadvantaged. Barriers remain with regards to accessibility and cost of services |
| Chakraborty et al. (2002) | Bangladesh, 1992–1993 | Cohort study with multi-stage random sampling                          | 1 020 | Moderate | In Bangladesh, four out of five women experience at least one morbidity during their index pregnancy and puerperium |
| Chatterjee and Paily (2011) | India, 2005–2006 | Cross-sectional nationally representative family health survey         | 131 596 | Low      | At the time of the study, only 20.3% of expenditure on health came from the government and 77.4% came from the patients’ pockets. There was very little insurance coverage available for maternity services in India, particularly in rural areas and user fees remain the norm for postnatal services |

| Study                          | Country, year          | Design                                      | n   | Quality*                  | Setting                                                                                                                                                                                                 |
|-------------------------------|------------------------|---------------------------------------------|-----|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Dhaher et al. (2008)†          | West Bank and Gaza Strip, 2006 | Cross-sectional study                      | 264 | Moderate                  | Study based in three clinics located in the three largest cities in the West Bank: northern Jerin, central Ramallah and southern Hebron. Clinics provide most of the reproductive health services and are referral clinics for surrounding villages and camps. |
| Dhakal et al. (2007)‡          | Nepal, 2006             | Cross-sectional study                      | 150 | Moderate                  | The study was conducted in two Village Development Committee (VDC) areas of Kathmandu district. These were slightly more developed than a typical VDC in Nepal.                                               |
| Halder et al. (2007)††         | Bangladesh, 2004        | Cross-sectional study, with multi-stage cluster sampling | 4838| Moderate                  | Although reproductive health services had been expanded in the two decades prior to the study, such services were available largely to the women in urban centres. Use of such services remained very low among the poor and in underserved rural areas. |
| Iyoke et al. (2011)†††         | Nigeria, 2007–2008      | Cross-sectional study                      | 371 | Low                       | Study based in two main tertiary hospitals in the south-eastern city of Enugu: University of Nigeria Teaching Hospital and Enugu State Teaching Hospital. At the time of the study, the estimated population of Enugu was 635,451 and most residents were civil servants or traders. |
| Jat et al. (2011)†             | India, 2007–2008        | Cross-sectional study – a nationwide household survey following a multi-stage stratified systematic sampling design | 15,782 | Moderate                  | At the time of the study, only 26.7% of Indians in Madhya Pradesh state resided in urban areas and the state was one of the poorest six states of India. About 38% of the state's population was living below the poverty line in 2004–2005. In 2008, there were 270 community health centres, 1149 primary health centres and 8834 health sub-centres in the state. These provided preventive and curative health-care services in rural areas. The state also had a huge network of private health-care facilities, although these were mainly concentrated in urban areas. |
| Kabakian-Khasholian and Campbell (2005)†    | Lebanon, 2000–2001 | Randomized controlled trial. Intervention versus placebo | 378 | High                      | At the time of the study, Lebanon lacked an organized health-care system and the public health-care sector only played a minor role. Four private hospitals – two in Beirut and two in the Bekaa region – were selected. All were privately owned and one in Beirut was a teaching hospital. These hospitals are located in urban areas but attract women from the suburbs of Beirut and from surrounding villages in the Bekaa. Similar to other facilities in Lebanon, postpartum practices in these hospitals are characterized by a short postpartum hospital stay and an absence of home follow-up. |
| Liu et al. (2011)‡‡            | China, 2005             | Cross-sectional study with multi-stage random sampling | 14,112| Moderate                  | Study based in western China, where most areas are mountainous with poor economic conditions and health services, and scarce information is available on the use of maternal health-care services. |
| Mahabub-Ul-Anwar et al. (2006)†| Bangladesh, 2004       | Cross-sectional survey                      | 848 | Low                       | Study based in rural areas where the government provides reproductive health services through its Health and Family Welfare Centres. At the time of the study, more than 60% of the population of these areas did not have access to basic health care and more than 80% of women received no postnatal care. In theory, the rural population had free access to primary health care, family planning and reproductive health services. However, the non-availability of service providers at government facilities in rural areas was a major problem. In the private health sector, the poor were not protected by any subsidized pricing structure. |
| Matijaevich et al. (2009)‡‡    | Brazil, 2004            | Cohort study                                | 3,497| High                      | The study was based in the southern city of Pelotas, when the city had a population of about 340,000 – 93% of them living in the urban area. Brazil's publicly funded health-care system offers free access to postnatal care for every woman. |
| Mistry et al. (2009)‡‡         | India, 1998–1999        | Cross-sectional study, with multi-stage sampling design | 11,648| Moderate                  | Study based in rural villages, most of which had low economic status and poor public health infrastructures. |
| Mullany et al. (2007)†‡†       | Nepal, 2003–2004        | Randomized controlled trial                 | 442 | High                      | Study based in an urban area.                                                                                                                                                                                |

| Mullany et al. (2008)11         | Myanmar, 2006–2007 | Cross-sectional population-based sample with two-stage cluster sampling | 2 252 | Low      | At the time of the study, about 560 000 individuals had been internally displaced within Shan, Karen, Karenni and Mon states, along Myanmar’s eastern border. Myanmar has one of the world’s least functioning health systems and within the conflict zones, there is practically no functioning public health sector and the performance indicators for obstetric care are even lower than national mean values. Study set in 25 communities in the Udi local government area, when the area had a general hospital, a cottage hospital and six maternity centres. The surveyed women resided in rural towns.   |
| Okafor (1991)16                 | Nigeria, 1988–1989 | Cross-sectional study                      | 498 | Moderate | Study conducted in 25 communities in the Udi local government area, when the area had a general hospital, a cottage hospital and six maternity centres. The surveyed women resided in rural towns.   |
| Rahman et al. (2011)1           | Bangladesh, 2007 | Cross-sectional study, with stratified, multi-stage cluster sampling | 10 996 | Moderate | At the time of the study, two thirds of the young mothers in Bangladesh lived in rural areas, more than one in six were uneducated and over three quarters were in unpaid jobs.   |
| Rai et al. (2012)10             | Nigeria, 2003–2008 | Cross-sectional study, with equal-probability systematic sampling | 2 434 | Moderate | At the time of the study, the third of the young mothers in Bangladesh lived in rural areas, more than one in six were uneducated and over three quarters were in unpaid jobs.   |
| Ram and Singh (2006)17          | India, 1998–2002 | Cross-sectional household survey           | 11 454 | Moderate | Study set in Uttar Pradesh, where, at the time of the study, around 90% of deliveries were conducted at home and nearly half the deliveries were only assisted by family or friends.   |
| Sarma and Rempel (2007)18       | India, 1995–1996 | Cross-sectional, nationally representative household survey | 16 592 | Moderate | At the time of the study, distance to the nearest source of postnatal care consistently had a negative effect on a woman's registration for – and use of – such care. Access to a bus service was an important positive determinant for the use of maternal health-care services in rural areas.   |
| Sharma et al. (2007)10          | Nepal, 1996–2001 | Quasi-experimental before-and-after study with no control group, but representative samples of the Nepalese population | 7 788 | Moderate | The Safe Motherhood Programme was implemented in Nepal in 1997. It was launched as a priority programme during the 1997–2002 plan period, with the aim of increasing women's access to health care and raising their status.   |
| Singh et al. (2012)10           | India, 2007–2008 | Cross-sectional nationwide household survey following a multi-stage stratified systematic sampling design | 93 416 | Moderate | At the time of the study, infant mortality rates in most Indian states appeared to be stabilizing rather than falling. Overall, there were 212 maternal deaths per 100,000 live births but levels of maternal mortality varied widely across the states. Although pregnant women were offered cash incentives to give birth in a health facility, there was no similar scheme in place to promote postnatal care.   |
| Singh et al. (2012)11           | India, 2005–2006 | Cross-sectional study with representative samples from all 29 states | 3 599 | Moderate | In 2005, the Indian government launched the National Rural Health Mission to improve health-system performance and people's health status in rural areas. A conditional cash-transfer scheme was also launched to promote institutional deliveries among women in rural areas.   |
| Stupp et al. (1994)12           | Belize, 1991    | Cross-sectional area-probability household survey with two stages of selection | 979  | Moderate | In rural areas of Belize, the tropical terrain and lack of roads – especially all-weather roads – reduce access to health care for rural women. Some ethnic groups may be particularly disadvantaged because they mainly live in rural settings.   |
| Tang and Li (2008)13            | China, 1998–2003 | Cross-sectional study with stratified cluster sampling | 462  | Low      | The study was based in poor regions of Sichuan province.   |
| Titaley et al. (2009)8          | Indonesia, 2002–2003 | Cross-sectional survey with systematic stratified random sampling | 15 553 | Low | Study conducted in 26 of Indonesia’s 30 provinces.   |
| Zere et al. (2010)14            | Namibia, 2006–2007 | Cross-sectional study                      | 9 804 | Low      | Namibia has one of the highest levels of income inequality in the world. At the time of the study, almost all Namibian women paid for delivery – mainly in cash but also in kind. However, 85% each paid less than the equivalent of 7.0 United States dollars.   |

Studies were considered to be of high, moderate and low quality if there was judged to be a very low, low and high risk of bias in the results, respectively.

---

Bull World Health Organ 2015;93:259–270C
Table 2. Socioeconomical determinants for the use of postnatal care services in low- and middle-income countries

| Study                        | Adjusted | Comparison groups                                      | Odds ratio* |
|------------------------------|----------|-------------------------------------------------------|-------------|
| Abel Ntambue et al. (2012)12 | No       | Woman's occupation, with housewife used as reference  | Estimated for use of PNC for no more than 7 days after the birth, for salesperson (0.8, 95% CI: 0.1–1.1), agricultural worker (0.6; 95% CI: 0.1–1.0) and public service worker (0.8; 95% CI: 0.4–1.3). The corresponding estimates for use of PNC for no more than 28 days after the birth were 0.9 (0.6–1.2), 0.7 (0.2–1.1) and 0.9 (0.7–1.4), respectively. The corresponding estimates for use of PNC for no more than 42 days were 1.0 (0.8–1.3), 0.8 (0.5–1.2) and 1.1 (0.7–1.6), respectively |
| Anwar et al. (2008)14        | Yes      | Wealth quintiles, with the fifth/poorest quintile used as reference | Estimated for fourth (1.31; NS), third (2.24; P < 0.001), second (3.11; P < 0.001) and first (4.38; P < 0.001) quintiles 4.98 (P < 0.001) |
| Anson (2004)15              | Yes      | Wealth quintiles, with the first/poorest quintile used as reference | Estimated for primary (1.73; P < 0.01), middle (1.33; NS) secondary (2.59; P < 0.001) and higher (3.97; P < 0.001) levels of education |
| Babalola and Fatusi (2009)15 | Yes      | Wealth quintiles, with none used as reference         | Estimated for second (1.85; P < 0.01), third (1.39; P < 0.01), fourth (2.05; P < 0.01) and fifth (2.92; P < 0.001) quintiles |
| Baqui et al. (2008)16       | No       | Wealth quintiles, with effect on home visits for PNC investigated | Estimated for use of PNC for no more than 7 days after the birth, for salesperson (0.8, 95% CI: 0.1–1.1), agricultural worker (0.6; 95% CI: 0.01–1.0) and public service worker (0.8; 95% CI: 0.4–1.3). The corresponding estimates for use of PNC for no more than 28 days after the birth were 0.9 (0.6–1.2), 0.7 (0.2–1.1) and 0.9 (0.7–1.4), respectively. The corresponding estimates for use of PNC for no more than 42 days were 1.0 (0.8–1.3), 0.8 (0.5–1.2) and 1.1 (0.7–1.6), respectively |

Inequities in postnatal care

| Study | Adjusted | Economic status, with good versus poor used as reference | Odds ratio* |
|-------|----------|-------------------------------------------------|-------------|
| Chakrabarty et al. (2002)** | Yes | Postnatal care by doctor/nurse/family-welfare visitor OR = 0.883 (0.276–2.823) | | |
| | | Postnatal care by other OR = 1.009 (0.599–1.700) | | |
| | | | | |
| Mother's education, with some versus none used as reference | Postnatal care by doctor/nurse/family-welfare visitor OR = 0.949 (0.387–2.328) | | |
| | | Postnatal care by other OR = 1.143 (0.760–1.719) | | |
| | | | | |
| Husband's occupation, with business/service versus other used as reference | Postnatal care by doctor/nurse/family-welfare visitor OR = 1.937 (0.809–4.634) | | |
| | | Postnatal care by other: OR = 2.096 (1.409–3.118) | | |
| | | | | |
| Women's gainful employment, with yes versus no used as reference | Postnatal care by doctor/nurse/family-welfare visitor OR = 0.873 (0.341–2.236) | | |
| | | Postnatal care by other: OR = 0.686 (0.473–0.996) | | |

| Dhafer et al. (2008)** | Yes | Level of education of woman and husband, with education of both above secondary level used as reference | Estimated for couples in which only the man (0.9; 95% CI: 0.3–2.2) or woman (95% CI: 1.5; 0.6–3.4) or neither individual (1.9; 95% CI: 0.8–4.5) was educated above secondary level |
| Dhalal et al. (2007)** | Yes | Woman's occupation, with farmer used as reference | Estimated for housewife (6.28; 95% CI: 2.00–19.69) and other (3.06; 95% CI: 0.27–34.64) occupations |
| | | Husband's occupation, with farmer used as reference | Estimated for males who have worked abroad and/or in the formal sector (0.83; 95% CI: 0.27–2.53) and for other non-farmers (0.15; 95% CI: 0.03–0.85) |

| Halder et al. (2007)** | Yes | Wealth index quintiles, with the first/poorest used as reference | Estimated for primary (1.25; 95% CI: 0.45–3.42) and secondary (6.49; 95% Cl. 2.5–17.2) levels |
| | | Woman's level of education, with illiterate used as reference | Estimated for primary (1.32; 95% CI: 0.28–6.92) and secondary (6.33; 95% CI: 1.55–29.95) levels |
| | | Husband's level of education, with illiterate used as reference | Estimated for second (1.223; NS), third (1.107; NS), fourth (1.723; P < 0.001) and fifth (2.188; P < 0.001) quintiles |
| | | Partner's occupation, with farmer used as reference | Estimated for primary (1.445; P < 0.001) and higher (1.935; P < 0.001) levels |
| | | | | |
| Halder et al. (2007)** | Yes | Wealth index quintiles, with the first/poorest used as reference | Estimated for agricultural and non-agricultural labourers (1.299; P < 0.05), semi-skilled labourers (1.204; NS), those who run small businesses (1.149; NS) and those in more well paid occupations (1.447; P < 0.05) |
| Iyoke et al. (2011)** | No | Income group, categorized as income earner or other, with other used as reference | Estimated for second (0.75), tertiary (1.38) and post-tertiary (1.23) education, with an overall P-value of 0.15 |
| | | Woman's level of education, with primary or less used as reference | Estimated for the poor (0.99; 95% CI: 0.85–1.14), moderately rich (1.13; 95% CI: 0.95–1.35), rich (1.03; 95% CI: 0.84–1.26) and richest (1.50; 95% CI: 1.16–1.93) |
| | | Socioeconomic status, with the poorest used as reference | 0.88 (95% CI: 0.79–0.98) |
| Jat et al. (2011)** | Yes | | |
| | | Woman's poverty index, categorized as holders or non-holders of a below-the-poverty-line ration card, with the holders used as reference | Estimated for primary (1.00; 95% CI: 0.86–1.15), middle (1.17; 95% CI: 0.99–1.37) and higher (1.39; 95% CI: 1.14–1.70) levels |
| | | Woman's level of education, with illiterate used as reference | Estimated for agricultural workers (0.92; 95% CI: 0.81–1.04) and professional, service or production workers (0.97; 95% CI: 0.77–1.23) |
| | | Woman's occupation, with unemployed used as reference | Estimated for primary (1.03; 95% CI: 0.87–1.21), middle (0.98; 95% CI: 0.83–1.15) and higher (1.14; 95% CI: 0.96–1.35) levels |
| | | Husband's level of education, with illiterate used as reference | Relative risk estimated to be 2.8 (95% CI: 2.2–3.4) |
| Kabakian-Khasholian and Campbell (2005)** | Yes | | |
| | | Intervention: information booklet in Arabic, covering the correct breastfeeding position; maternal health problems; importance of the postnatal check-up at 6 weeks after the birth, father's role in the postnatal period and family planning | Relative risks estimated for secondary (1.8; 95% CI: 1.1–2.5) and university (2.7; 95% CI: 2.1–3.4) levels |
| | | Women's level of education, with below secondary used as reference | |

| Liu et al. (2011)52           | Yes      | Wealth index, categorized as: poor, middle or rich, with poor used as reference   | Estimated for the middle (1.28, 95% CI: 1.01–1.63) and rich (1.36, 95% CI: 1.03–1.80) categories |
|                               |          | Woman’s level of education, with primary used as reference                        | Estimated for secondary (1.00, 95% CI: 0.85–1.18) and high school (1.13; 95% CI: 0.91–1.49) levels |
|                               |          | Husband’s level of education, with primary used as reference                     | Estimated for secondary (0.89; 95% CI: 0.76–1.06) and high school (0.75; 95% CI: 0.48–1.16) levels |
| Mahabub-Ul-Anwar et al. (2006) | No      | Wealth group quintile, with first/poorest used as reference                      | Estimated for the second (1.01), third (1.34), fourth (1.47) and fifth (2.31) quintiles |
| Matijasevich et al. (2009)    | Yes      | Family income quintiles, with the fifth/richest used as reference               | Estimated for the first (2.61; 95% CI: 1.85–3.66), second (2.17; 95% CI: 1.55–3.05), third (2.02; 95% CI: 1.44–2.82) and fourth (1.51; 95% CI: 1.07–2.13) quintiles, with an overall P-value of less than 0.001 |
| Mistry et al. (2009)14         | Yes      | Insurance scheme, categorized as public or private, with private used as reference | 3.08 (1.99–4.79) |
|                               |          | Woman’s years of schooling, with over 9 years used as reference                   | Estimated for 0–4 (2.64; 95% CI: 2.01–3.48) and 5–8 (2.04; 95% CI: 1.64–2.54) years, with an overall P-value of less than 0.001 |
| Mistry et al. (2009)14         | Yes      | Woman’s standard of living, categorized as low, medium or high, with low used as reference | Estimated for the medium (1.21; 95% CI: 1.06–1.39) and high (1.84, 95% CI: 1.49–2.28) categories |
| Mistry et al. (2007)15         | Yes      | Woman’s employment status, categorized as currently employed or unemployed, with unemployed used as reference | 0.93 (95% CI: 0.82–1.06) |
| Mulany et al. (2006)6         | Yes      | Woman’s years of education                                                        | 1.07 (95% CI: 1.06–1.09) |
|                               |          | Partner’s years of education                                                      | 1.00 (95% CI: 0.98–1.01) |
| Okafor (1991)16               | Yes      | Intervention: antenatal health education sessions on birth preparedness and use of maternal health care, with non-intervention group used as reference | Relative risks estimated for a couples group (1.29; 95% CI: 1.04–1.60) and a women-only group (1.03; 95% CI: 0.82–1.31) |
| Rahman et al. (2011)6         | Yes      | Woman’s years of education                                                        | 1.10 (P < 0.01) |
|                               |          | Woman’s wealth index, with poorest used as reference                              | Estimated – in a comparison of skilled PNC versus unskilled or no such care — for the poor (1.11; 95% CI: 0.67–1.51), middle (1.43; 95% CI: 1.11–2.06), richer (1.61; 95% CI: 1.34–1.97) and richest (2.12; 95% CI: 1.68–2.58). In a comparison of PNC on 1 or 2 days with more days of PNC, the corresponding values were 1.24 (0.83–1.86), 1.75 (0.94–1.82), 1.84 (1.23–2.76) and 2.08 (1.68–2.58), respectively |
|                               |          | Woman’s level of education, with none used as reference                           | Estimated – in a comparison of skilled PNC versus unskilled or no such care — for incomplete (1.33; 95% CI: 0.78–1.49) and complete primary (1.41; 95% CI: 0.81–1.68), incomplete secondary (1.53; 95% CI: 1.12–2.00) and higher (2.03; 95% CI: 1.42–2.86) levels. In a comparison of PNC on 1 or 2 days with more days of PNC, the corresponding values were 1.07 (0.82–1.32), 1.17 (0.94–1.45), 1.51 (1.11–2.06) and 1.84 (1.23–2.76), respectively |
|                               |          | Woman’s occupation, categorized as paid job or unpaid job, with unpaid used as reference | Estimated – in a comparison of skilled PNC versus unskilled or no such care — as 1.22 (95% CI: 0.91–1.44). In a comparison of PNC on 1 or 2 days with more days of PNC, the corresponding value was 1.14 (0.83–1.56) |
|                               |          | Husband’s occupation, with manual labour used as reference                        | Estimated – in a comparison of skilled PNC versus unskilled or no such care — for agricultural workers and the self-employed (1.02; 95% CI: 0.84–1.77), professional, technical and managerial workers (2.22; 95% CI: 1.62–2.81) and other occupations (1.93; 95% CI: 1.23–2.67). In a comparison of PNC on 1 or 2 days with more days of PNC, the corresponding values were 1.11 (0.85–1.56), 1.61 (1.32–1.97) and 1.14 (0.83–1.56), respectively |
| Rai et al. (2012)20           | Yes      | Wealth quintile, with first/poorest used as reference                            | Estimated for second (0.976, 95% CI: 0.705–1.352), third (1.310; 95% CI: 0.908–1.889), fourth (1.453, 95% CI: 0.907–2.326) and fifth (1.465, 95% CI: 0.688–3.121) quintiles |
|                               |          | Woman’s work status, with not working used as reference                          | Estimated for working at home (1.12; 95% CI: 0.828–1.492) and away from home (1.132; 95% CI: 0.809–1.584) |
|                               |          | Woman’s level of education, with none used as reference                          | Estimated for primary but below middle (1.534; 95% CI: 1.067–2.206) and for secondary and above (1.116; 95% CI: 0.706–1.765) |
|                               |          | Husband’s level of education, with none used as reference                        | Estimated for primary but below middle (1.405; 95% CI: 0.990–1.993) and for secondary and above (1.638; 95% CI: 1.137–2.361) |
