On a possible manifestation
of the four color symmetry $Z'$ boson
in $\mu^+\mu^-$ events at the LHC

Abstract

The cross section of the $\mu^+\mu^-$ pair production in $pp$-collisions at the LHC is
calculated with account of the $Z'$ boson induced by the minimal four color quark-
lepton symmetry ($MQLS$). The $\mu^+\mu^-$ invariant mass spectrum with account of the
$MQLS Z'$ boson is analysed in dependence on the $Z'$ mass. The mass region for the
$MQLS Z'$ boson observable at the LHC is found in dependence on the significance
and on the integrated luminosity.

Keywords: Beyond the SM; four color symmetry; Pati–Salam; $Z'$ boson; LHC.
PACS number: 12.60.-i

The search for a new physics beyond the Standard Model (SM) is an actual field of
the elementary particle physics now. The near start of LHC will essentially enlarge the
possibilities for search for new physics effects and in this situation the extensions of SM
predicting new efects at the LHC energies (such as supersymmetry, left–right symmetry,
two Higgs model, etc.) acquire the special interest.

One of the possible variants of such new physics can be induced by the possible four
color quark–lepton symmetry of Pati–Salam type treating leptons as the fourth color [1].
The immediate consequence of this symmetry is the prediction of the specific new gauge
particles – vector or chiral gauge leptoquarks and one or two additional neutral $Z'$ bosons.
In particular case of the minimal unification with the SM by the gauge group

$$G_{new} = SU_V(4) \times SU_L(2) \times U_R(1)$$

(MQLS model [2, 3]) the four color symmetry (described here by the vector color group
$SU_V(4)$) predicts one vector leptoquark $V^\pm$ with electric charge $\pm 2/3$ and one additional
neutral $Z'$ boson. The interactions of these gauge fields with fermions are defined by the
group [1] and give the possibility to investigate quantitatively the effects of these paricles
in dependence on their masses. Below we concentrate our attention on the additional
$Z'$ boson predicted by the four color symmetry unified with SM by the minimal group [1].

*E-mail: asmirnov@univ.uniyar.ac.ru
†E-mail: zajax.jr@mail.ru
It should be noted that additional $Z'$ bosons appear in many extensions of the SM. In dependence on the model the most stringent lower limits on $Z'$ masses are of order $M_{Z_1} > 0.822$ TeV [4] for $Z'$ bosons of $E_6$ model from $Z'$ direct searches at the Tevatron [5] and $M_{Z_{LR}} > 0.86$ TeV, $M_{Z'_{SM}} > 1.5$ TeV [4] for $Z'$ bosons of LR model and of the model with SM coupling constants from the global electroweak analysis [6].

The most stringent mass limit for the MQLSM $Z'$ boson can be extracted from the LEP leptonic cross section of its possible deviation from the SM prediction will give the possibility to detect the $Z' \rightarrow \gamma,Z,Z'$ production at the LHC can be the possible excess of $\mu$ leptonic cross section or to set the new mass limit on its mass. So the analysis of the process $pp \rightarrow \gamma,Z,Z' \rightarrow \mu^+\mu^-$ at the LHC energy is of interest.

In the present paper we calculate the cross section of lepton-antilepton pair production in $pp$-collisions at the LHC with account of $Z'$-boson predicted by the the four color symmetry of type (I). We obtain and discuss the mass region in which this $Z'$ can be discovered at the LHC in comparison with the other models ($E_6, LRM, SSM$ [8,9]) also predicting $Z'$ bosons.

Interactions of the neutral gauge bosons with the SM fermions can be written as

$$\mathcal{L}_{NC}^{gauge} = -|e| \sum_i J^i_\mu A^i_\mu,$$

where $e$ is an electron charge, $A_i (i = 0, 1, 2)$ denote the gauge boson $\gamma, Z, Z'$,

$$J^i_\mu = \sum_{f_a} \bar{f}_a \gamma_\mu (v^i_{fa} + a^i_{fa}) f_a$$

are the neutral currents and $v^i_{fa} \equiv v^A_i$ and $a^i_{fa} \equiv a^A_i$ are the vector and axial coupling constants of fermion $f_a$ with gauge boson $A_i$ ($f$ is quark or lepton, $a = 1, 2$ for up and down fermion).

In general case the mass eigenstates $Z$ and $Z'$ are superposition of two basic fields $Z_1$ and $Z_2$. With account of $Z-Z'$ mixing the coupling constants of $Z$ and $Z'$ with fermions can be written as

$$v^Z_{fa} = v^Z_{fa} \cos \theta_m - v^{Z'}_{fa} \sin \theta_m, \quad a^Z_{fa} = a^Z_{fa} \cos \theta_m - a^{Z'}_{fa} \sin \theta_m,$$

$$v^{Z'}_{fa} = v^{Z'}_{fa} \sin \theta_m + v^Z_{fa} \cos \theta_m, \quad a^{Z'}_{fa} = a^{Z'}_{fa} \sin \theta_m + a^Z_{fa} \cos \theta_m,$$

where

$$v^1_{fa} = \frac{(\tau_3)_{aa} - 4Q_{fa}s_W^2}{4s_Wc_W}, \quad a^1_{fa} = \frac{(\tau_3)_{aa}}{4s_Wc_W}$$

are the SM coupling constants, $\theta_m$ is the $Z-Z'$ mixing angle, $s_W = \sin \theta_W$, $c_W = \cos \theta_W$, $\theta_W$ is the Weinberg weak mixing angle, $\tau_3$ is the Pauli matrix, $Q_{fa}$ is electric charge of fermion $f_a$ in part of $|e|$.

$$m_{Z'} > 1.4 \text{ TeV}.$$
The interaction of \( Z \) field with fermions depends on the origin of this field. In MQLS model the coupling constants \( v_{f_a}^{Z_2}, a_{f_a}^{Z_2} \) have the form [10]

\[
v_{f_a}^{Z_2} = \frac{1}{c_W s_S \sqrt{1-s_W^2-s_Z^2}} \left[ \frac{2}{3} (t_{15})_f - (Q_{f_a} - \frac{(\tau_3)_{aa}}{4}) s_S^2 \right],
\]

\[
a_{f_a}^{Z_2} = \frac{s_S}{c_W \sqrt{1-s_W^2-s_Z^2}} \frac{(\tau_3)_{aa}}{4}
\]

where \( t_{15} \) is the 15-th generator of \( SU_V(4) \) group, \( s_S = \sin \theta_S \) is the parameter of the model defined be relation of electromagnetic and strong coupling constants, \( \theta_S \) is a strong mixing angle. In MQLS model the \( Z - Z' \) mixing angle is small (\( \theta_m < 0.006 \)) and we neglect below the \( Z - Z' \) mixing believing \( Z \approx Z_1 \) and \( Z' \approx Z_2 \).

The differential cross-section of lepton-antilepton pair production in fermion-antifermion collision in the tree approximation is well known and for \( m_f \ll \sqrt{s} \) can be written as [8,9]

\[
d\sigma(\bar{f}_a f_a \rightarrow \gamma^{Z,Z'} l^+ l^-) = \frac{\pi \alpha^2}{2N_c} \sum_{i,j} \left( 2z B_{f_a l}^{ij} + (z^2 + 1) C_{f_a l}^{ij} \right) P_{ij}(s) dz.
\]

Here \( \alpha \) is the fine structure constant, \( s \) is the invariant mass square of the initial \( \bar{f} f \) pair, \( N_c = 1(3) \) denote colour factor for leptons (quarks), \( z = \cos \theta \), \( \theta \) is the scattering angle in the center of mass frame, \( B_{f_a l}^{ij}, C_{f_a l}^{ij} \) are the combinations of the coupling constants of the form

\[
C_{f_a l}^{ij} = (a_{f_a}^i a_{f_a}^j + v_{f_a}^i v_{f_a}^j)(a_{f_a}^i a_{f_a}^j + v_{f_a}^i v_{f_a}^j),
\]

\[
B_{f_a l}^{ij} = (a_{f_a}^i v_{f_a}^j + a_{f_a}^j v_{f_a}^i)(a_{f_a}^i v_{f_a}^j + a_{f_a}^j v_{f_a}^i),
\]

\( P_{ij}(s) = Re(P_i(s)P_j^*(s)) \) and \( P_i(s) = 1/(s - M_i^2 + i M_i \Gamma_i) \) is a factor coming from propagator of boson \( A_i \) with mass \( M_i \equiv M_{A_i} \) and with width \( \Gamma_i \equiv \Gamma_{A_i} \).

Integration of (10) over \( z \) gives the total cross-section in the form

\[
\sigma(\bar{f}_a f_a \rightarrow \gamma^{Z,Z'} l^+ l^-) = \frac{4\pi s \alpha^2}{3N_c} \sum_{i,j} C_{f_a l}^{ij} P_{ij}(s).
\]

The differential cross-section of \( \mu^+ \mu^- \) pair production in proton–proton collision (Drell–Yan process) with account of an aditional \( Z' \)-boson can be written as

\[
d\sigma(pp \rightarrow \gamma^{Z,Z'} \mu^+ \mu^-) = \sum_k F_k(x_1, x_2, s) \sigma(q_k \bar{q}_k \rightarrow \gamma^{Z,Z'} \mu^+ \mu^-) dx_1 dx_2
\]

where \( s = x_1 x_2 S, S \) is total energy square of colliding protons, \( x_{1,2} \) is parton fraction of proton momentum and the function \( F_k(x_1, x_2, s) \) can be expressed in the terms of parton distribution functions \( f_{q_k}(x_1, s) \) (\( f_{\bar{q}_k}(x_1, s) \)) of \( k \)-flavor quarks \( q_k \) (antiquarks \( \bar{q}_k \)) as

\[
F_k(x_1, x_2, s) = f_{q_k}(x_1, s)f_{\bar{q}_k}(x_2, s) + f_{\bar{q}_k}(x_1, s)f_{q_k}(x_2, s).
\]

For the further analysis it is useful to go over from the variables \( \{x_1, x_2\} \) to

\[
M^2 = x_1 x_2 S, \quad y = \ln \frac{x_1}{x_2}
\]
where $M$ is invariant mass of quark-antiquark pair (which is equal to invariant mass of the final $\mu^+\mu^-$ pair), $y$ is the final lepton rapidity, $\sqrt{s}$ is the energy of colliding protons. In terms of the variables $\{M, y\}$ the cross section (12) takes the form

$$d\sigma(pp \rightarrow \gamma, Z') = \frac{8\pi M^3\alpha^2}{9S} \sum_k F_k(M) \sum_{i,j} C_{q_k\mu}^{ij} P_{ij}(M^2) dM dy.$$  

Integration of the cross section (14) over $y$ gives the $\mu^+\mu^-$ invariant mass spectrum in the form

$$\frac{d\sigma(pp \rightarrow \gamma, Z')}{dM} = \frac{8\pi M^3\alpha^2}{9S} \sum_{i,j} I^{ij}(M, S) P_{ij}(M^2)$$  

where

$$I^{ij}(M, S) = \sum_k I_k(M, S) C_{q_k\mu}^{ij},$$

$$I_k(M, S) = \int_{-\ln \sqrt{s}/M}^{+\ln \sqrt{s}/M} F_k(M, S) e^{y} e^{-y} e^{-y} M^2 dy.$$  

The analysis of the possible new effects in $\mu^+\mu^-$ invariant mass spectrum at the LHC was performed by CMS collaboration [11, 12]. This analysis is based on the statistical significance $S'$ estimation of the signal $pp \rightarrow \gamma, Z' \rightarrow \mu^+\mu^-$ events in the presence of the background $pp \rightarrow \gamma, Z \rightarrow \mu^+\mu^-$ events, with $Z'$ predicted by some models ($E_6, LRM, ALRM, SSM$). There are different definitions of significance estimators in literature and we use here the next one [13]

$$S' = \sqrt{2} [(N_s + N_b) \ln (1 + N_s/N_b) - N_s]$$

where $N_s$ and $N_b$ are number of signal and background events in the dilepton invariant mass region $M_{Z'} \pm \Delta M$. The numbers $N_s$ and $N_b$ can be calculated from the cross sections of type (15) as

$$N_s = L \sigma_s(M_{Z'}, \Delta M), \quad \sigma_s(M_{Z'}, \Delta M) = \int_{M_{Z'}-\Delta M}^{M_{Z'}+\Delta M} \frac{d\sigma(pp \rightarrow \gamma, Z')}{dM} dM, \quad (19)$$

$$N_b = L \sigma_{SM}(M_{Z'}, \Delta M), \quad \sigma_{SM}(M_{Z'}, \Delta M) = \int_{M_{Z'}-\Delta M}^{M_{Z'}+\Delta M} \frac{d\sigma(pp \rightarrow \gamma, Z')}{dM} dM \quad (20)$$

where $L = \int \mathcal{L} dt$ is the integrated luminosity, $\sigma_s(M_{Z'}, \Delta M)$ and $\sigma_{SM}(M_{Z'}, \Delta M)$ are the cross sections for the signal and background events in the mass region $M_{Z'} \pm \Delta M$. Here $\Delta M$ is a mass window chosen below as $\Delta M = 0.85 \Gamma_{Z'}$, which corresponds to the width of 2$\sigma$ in the case of Gaussian distribution [14].

The $\mu^+\mu^-$ invariant mass spectrum (15) depends on the mass $M_{Z'}$ and on the width $\Gamma_{Z'}$ of $Z'$ boson. The fermionic decays of $Z'$ boson are defined by the coupling constants (6–9) and the corresponding partial widths of $Z'$ boson decays to $f_a\bar{f}_a$ pairs for $m_{f_a} \ll M_{Z'}$ have the form

$$\Gamma(Z' \rightarrow f_a\bar{f}_a) = N_f M_{Z'} \frac{\alpha}{3} ((v_{f_a}^{Z'})^2 + (a_{f_a}^{Z'})^2)$$

where the color factor $N_f = 1(3)$ for leptons(quarks) $f = l(q)$. 

In the case of the Higgs mechanism of the fermion mass generation the four color symmetry of type (1) in addition to the SM Higgs doublet predicts the new scalar doublets: the color octet of scalar gluon doublets $F_a$, $a = 1, \ldots, 8$, two color triplets of scalar leptoquark doublets $S^{(\pm)}_{a\alpha}$, $\alpha = 1, 2, 3$ and additional colorless scalar doublet $\Phi'$ as well as some other scalar fields (more details can be found in [15]). The analysis of the mass limits for the scalar doublets $F_a$, $S^{(\pm)}_{a\alpha}$, $\Phi'$ from $S$, $T$, $U$ parameters of electroweak radiative corrections [16,17], from $K_L^0 \to e^\mp \mu^\pm$ and $B^0 \to e^\mp \tau^\pm$ decays [4,18,19], from the magnetic moments of muon [20] and of neutrino [21] showed that these scalar doublets can be light, with masses below 1 TeV. So, the MQLSM $Z'$ boson can decay also into pairs of these scalar particles, which gives the additional to (21) contributions to $Z'$ width.

Writing the interaction of $Z'$ boson with scalar field $\Phi$ as

$$\mathcal{L}_{Z'\Phi} = ig_{Z'\phi}Z'_\mu (\partial^\mu \Phi^* - \Phi^* \partial^\mu \Phi)$$

(22)

where $g_{Z'\phi}$ is the corresponding coupling constant for the width of $Z'$ boson decay into $\Phi\Phi$ pair we have the expression

$$\Gamma(Z' \to \Phi\Phi) = N_\Phi M_{Z'} \frac{g_{Z'\phi}^2}{48\pi} \left(1 - \frac{4m_\phi^2}{M_{Z'}^2}\right)^{3/2}$$

(23)

where $N_\Phi$ is the color factor ($N_{F_a} = 8$ for scalar gluons, $N_{S^{(\pm)}_{a\alpha}} = 3$ for scalar leptoquarks, $N_{\Phi'} = 1$ for the additional colorless scalar doublet) and $m_\phi$ is a mass of the scalar particle.

The scalar gluons $F_a$ and the scalar leptoquarks $S^{(\pm)}_{a\alpha}$ gives the main contribution into $Z'$ boson width of type (23). The coupling constants of these particles with $Z'$ boson are predicted by the MQLS model as

$$g_{Z'F_a} = -\frac{e}{2} \frac{\sigma}{s_W c_W}, \quad g_{Z'S^{(\pm)}_{a\alpha} \Phi^{(\pm)}} = -e \left(\frac{\sigma}{2s_W c_W} \pm \frac{2t_W}{3\sigma}\right)$$

(24)

where $t_W = \tan \theta_W$ and $\sigma = s_W s_S/\sqrt{1 - s_W^2 - s_S^2}$.

The partial widths of $Z'$ decays into scalar gluon and scalar leptoquark pairs of type (23), (24) depend on parameter $s_S$ and on masses of these scalar particles and on $Z'$ mass $M_{Z'}$. The parameter $s_S$ is defined by the mass scale $M_c \sim M_V$ of the four-color symmetry breaking and by the intermediate mass scale $M' \sim M_{Z'}$ [3,15]. For example for $M' \sim 10$ TeV and for $M_c = 10^4$ TeV, $10^6$ TeV, $10^8$ TeV we have $s_S^2 = 0.070, 0.112, 0.154$ respectively [15]. For numerical estimations we use below the value $s_S^2 = 0.114$ which corresponds to $M_{Z'} \sim 1 - 5$ TeV and $M_c \sim 10^3$ TeV. The current mass limits for scalar leptoquarks are of about $m_{S^{(\pm)}} \gtrsim 250 - 300$ GeV in dependence on details of their interactions with fermions [4]. At the present time there are no reliable experimental mass limits for the scalar gluons but it is reasonable to expect their masses to be of the same order or slightly greater than the scalar leptoquark ones. Below in calculations we use for the masses of the scalar leptoquarks and of the scalar gluons the value 300 GeV. With these values of $s_S^2$ and of the masses of scalar particles the relative total width of $Z'$--boson $\Gamma_{Z'}/M_{Z'}$ occurs to be equal to

$$\Gamma_{Z'}/M_{Z'} = 4.3\% (1.1\%, 3.2\%), \quad 5.2\% (2.0\%, 3.2\%), \quad 5.3\% (2.1\%, 3.2\%)$$

(25)

for $M_{Z'}$ of about respectively 1 TeV, 3 TeV, 5 TeV and above, the corresponding values of the relative widths of the $Z'$ decays respectively into scalar particles and into fermions are shown in parenthesis.
The computation of the cross sections [15] has been performed with using the set of parton distribution functions [22] in the leading order with the fixed flavor number scheme. The figure 1 shows the cross sections \( \sigma_s(M_{Z'}, \Delta M) \) of \( \mu^+\mu^- \) pair production at the LHC energy with account of \( Z' \) boson of the MQLS model in comparison with \( E_6 \), LRM and SSM models as well as the background cross section \( \sigma_{SM}(M_{Z'}, \Delta M) \) predicted in the SM (for the mass window of MQLS \( Z' \) boson). As seen the signal cross section in all the models (incuding the MQLS model) essentially exceeds the background one.

Comparing the results of the MQLS, \( E_6 \), LRM and SSM models it should be noted that the MQLS model predicts the relatively large leptonic vector coupling constant \( v^Z_{\mu} \sim -1.1 \) and mainly due to this circumstance in the MQLS model the value of \( I^{Z'}_{\mu}(M, S) \) in [15] exceeds the corresponding values in \( E_6 \), LRM and SSM models, which increases the MQLSM cross section. On the other hand the width of \( Z' \) boson in MQLS model with account of the scalar and fermionic decays is predicted to be larger than that in \( E_6 \), LRM and SSM models (for example, at \( M_{Z'} = 3 \) TeV we obtain \( \Gamma_{Z'}/M_{Z'} = 5.2\%, 0.5\%, 2.1\%, 3.1\% \) in MQLS, \( E_6 \), LRM, SSM models respectively), which decreases the MQLSM cross section due to decreasing the factor \( P_{ij}(M^2) \). As a result as we see in the figure 1 the signal cross section in MQLS model still exceeds the prediction of \( E_6 \) model and approximately coincides with those in LRM and SSM models.

The figure 2 shows the integrated luminosity which is necessary for the observation of \( Z' \) boson of the MQLS model at 5\( \sigma \) significance (\( S' = 5 \)) in dependence on \( Z' \) mass in comparison with \( E_6 \), LRM and SSM models. From the figure 2 and using also the formulas (15)–(20) we obtain that \( Z' \) boson of the MQLS model with masses

\[
M_{Z'} < 2.44 \pm 0.13 \text{ TeV}, \quad M_{Z'} < 3.50 \pm 0.22 \text{ TeV}, \quad M_{Z'} < 4.67 \pm 0.31 \text{ TeV}
\]

(26)
can be observed in \( \mu^+\mu^- \) events at the LHC with 5\( \sigma \) significance at integrated luminosity \( L = 1 \) fb\(^{-1}, 10 \) fb\(^{-1}, 100 \) fb\(^{-1} \) with expected numbers of signal (background) events \( N_s(N_b) = 3.47(0.038), 3.45(0.036), 3.34(0.031) \) respectively. The uncertainties in (26) are caused by those in parton distribution functions.

Table 1: The upper \( Z' \) boson masses in MQLS model observable at the LHC in dependence on integrated luminosity \( L \) and on significance \( S' \sigma \) in comparison with \( E_6 \), LRM, SSM models

| \( L, \text{ fb}^{-1} \) | MQLSM | \( E_6 \) | LRM | SSM |
|-----------------|---------|---------|-----|-----|
| \( 5\sigma \) | \( 3\sigma \) | \( 1\sigma \) | \( 5\sigma \) | \( 3\sigma \) | \( 1\sigma \) |
| 1               | 2.44    | 2.90    | 3.95 | 2.18 | 2.50 | 2.67 |
| 10              | 3.50    | 4.01    | 5.14 | 3.18 | 3.57 | 3.74 |
| 100             | 4.67    | 5.19    | 6.38 | 4.28 | 4.72 | 4.89 |

The central values in (26) and the corresponding values for 3\( \sigma \) and 1\( \sigma \) significances in MQLS model are shown in the first columns of the Table1. As seen the MQLSM \( Z' \) boson with masses

\[
M_{Z'} < 5.2 \text{ TeV}
\]

(27)
can manifest itself in \( \mu^+\mu^- \) events at the LHC at integrated luminosity 100 fb\(^{-1} \) with 3\( \sigma \) significance, while for

\[
M_{Z'} > 6.4 \text{ TeV}
\]

(28)
it its effect in \( \mu^+\mu^- \) events will not exceed 1\( \sigma \) i.e. it will be practically invisible at the LHC.
For comparison with the MQLS model the last three columns of the Table [1] show the $5\sigma$ predictions of $E_6$, $LRM$, $SSM$ models. As seen the central values in (26) exceed the corresponding predictions of $E_6$ model and are near the predictions of $LRM$ and are slightly below the predictions of $SSM$ model. It is worthy to note that the MQLSM $Z'$ boson has some specific features [10] which give the possibility in the case of observation of $Z'$ boson to identify its origin.

In conclusion, we resume the results of the work.

The cross section of the $\mu^+\mu^-$ pair production in $pp$-collisions at the LHC is calculated and analysed with account of the $Z'$ boson induced by the four color quark-lepton symmetry (MQLS). The corresponding $\mu^+\mu^-$ invariant mass spectrum with account of the $Z'$ boson width is analysed in dependence on the $Z'$ mass. The mass region for the MQLS $Z'$ boson observable at the LHC is found in dependence on the significance and on the integrated luminosity. In particular, it is shown that the MQLS $Z'$ boson can be observable at the LHC with $3\sigma$ significance at $L = 100 \, fb^{-1}$ up to $M_{Z'} < 5.2 \, TeV$. The results are discussed in comparison with predictions of $E_6$, $LRM$, $SSM$ models.
