Abstract (247 words)

Objective: To determine the change in non-invasive ventilation (NIV) use over time in infants born at <32 weeks’ gestation and the associated clinical outcomes.

Study design: Retrospective cohort study using routinely recorded data from the National Neonatal Research Database of infants born at <32 weeks admitted to neonatal units in England and Wales from 2010 to 2017.

Results: In 56,537 infants, NIV use increased significantly between 2010 and 2017 (Continuous Positive Airway Pressure (CPAP) from 68.5% to 80.2% in 2017 and high flow nasal cannula (HFNC) from 14% to 68% respectively) (p<0.001)). Use of NIV as the initial mode of respiratory support also increased (CPAP, 21.5% to 28.0%; HFNC, 1% to 7%; (p<0.001)).

HFNC was used earlier, and for longer, in those who received CPAP or mechanical ventilation. HFNC use was associated with decreased odds of death before discharge (aOR 0.19, 95% CI 0.17-0.22). Infants receiving CPAP but no HFNC died at an earlier median chronological age: CPAP group, 22 (IQR 10-39) days; HFNC group 40 (20-76) days (p<0.001). Among survivors, HFNC use was associated with increased odds of bronchopulmonary dysplasia (BPD) (aOR 2.98, 95% CI 2.81-3.15) and other adverse outcomes.

Conclusions: NIV use is increasing, particularly as initial respiratory support. HFNC use has increased significantly with a 7-fold increase soon after birth which was associated with higher rates of BPD. As more infants survive with BPD, we need robust clinical evidence, to improve outcomes with the use of NIV as initial and ongoing respiratory support.
Ethical approval

The dataset was created by the NDAU and this study was approved by Yorkshire & The Humber – Sheffield Research Ethics Committee (IRAS 259802).

Key words: nasal continuous positive pressure ventilation; high flow nasal cannula oxygen; bronchopulmonary dysplasia

Abbreviations: aOR, adjusted odds ratio; BPD, bronchopulmonary dysplasia; CPAP, continuous positive airway pressure; CI, confidence interval; GA, gestational age; HFNC, high flow nasal cannula oxygen; IQR, inter-quartile range; MD, median difference; NEC, necrotising enterocolitis; NIV, non-invasive ventilation; NNRD, National Neonatal Research Database; ROP, retinopathy of prematurity; SD, standard deviation.
What is already known on this topic

- Non-invasive ventilation (NIV) is being used increasingly to provide respiratory support to very preterm infants.
- While Continuous Positive Airway Pressure (CPAP) remains the mainstay of NIV, High flow nasal cannula oxygen (HFNC) is a popular mode of NIV and clinicians have reported increasing preference of using HFNC.

What this study adds

- NIV support, particularly HFNC, in very preterm infants increased significantly between 2010 and 2017 in England and Wales.
- HFNC is increasingly used as initial respiratory support in extremely preterm infants, although there is a high rate of such infants requiring CPAP or mechanical ventilation within 7 days.
**Introduction**

In very preterm infants, increased use of antenatal steroids, early surfactant, and attempts to minimise lung injury have encouraged increased use of non-invasive ventilation (NIV).[1] Modalities such as nasal continuous positive airway pressure (CPAP) that provide a set distending pressure prevent some adverse effects associated with mechanical ventilation.[2] Similarly, high flow nasal cannula oxygen (HFNC), which delivers a set gas flow, rather than a set distending pressure, has become increasingly popular.[3]

Continuous distending pressure directly, or generated via a continuous flow of oxygen-air mixture, stabilises the upper airway, maintains lung volumes, and stimulates upper airways to maintain a respiratory drive.[1] These mechanisms can reduce the need for prolonged invasive ventilation and may reduce the risk of bronchopulmonary dysplasia (BPD) and other ventilator-induced lung injuries.[4] Meta-analyses suggest that, when used for initial respiratory support or as respiratory support after extubation, HFNC and CPAP are not different when comparing the risks of BPD and death in preterm infants.[5] Both are now frequently used. Although UK clinicians’ report increased use of HFNC [6], there are no data quantifying the change in use of NIV in actual practice.

We aimed to quantify the change in use of NIV in infants born at <32 weeks’ gestation across England and Wales from 2010 to 2017 and analysed the association between these changes and clinical outcomes.

**Methods**

We performed a retrospective cohort study of infants born at <32 weeks’ gestation in England and Wales from 01 January 2010 to 31 December 2017 inclusive, whose data are held within the UK National Neonatal Research Database (NNRD).[7] [8]
Infants were excluded if there were missing data as described in Supplementary Figure 1 and Supplementary Table 1.[7].

Exposures
From variables that record types of respiratory support received (invasive ventilation, NIV, supplemental oxygen, type of NIV), we identified infants who received any NIV (Supplementary Table 1). Infants who received NIV were divided into two groups – those who received HFNC for any length of time (HFNC group) and those who received CPAP and had no record of receiving HFNC (CPAP only group). Infants in the HFNC group may have received CPAP also.

Outcomes
BPD was defined as requiring any supplementary oxygen or respiratory support at 36 weeks’ CGA (infants who died before 36 weeks were excluded) [9]. Other pre-planned outcomes and their definitions are given in Supplementary Table 1.

Statistical Analysis
All data management and analyses were performed using STATA, version 15.1 (StataCorp, College Station, Tx). After exclusions, we quantified the percentage of all admissions each year where HFNC was used, both for all infants and for two pre-specified subgroups: those born at <28 weeks’, and those born at 28-31 weeks’ gestation. We compared the study groups, including demographic, pregnancy and delivery and the NMR-2000 score to describe infants’ risk of in-hospital mortality.[10]

We quantified and described changes in the highest mode of respiratory support received on the first day after birth. We described the percentage who subsequently ‘failed’ on the initial mode as those who had escalation of respiratory support within 7 days i.e., for those on
HFNC initially, if they received CPAP and/or mechanical ventilation and for those on CPAP initially, if they received mechanical ventilation. Where HFNC was not the initial mode of respiratory support, we quantified subsequent exposure to HFNC. Change in use over the study period (2010-2017) was analysed using the Chi-squared test for trends.

We used logistic regression for binary variables and quantile regression for continuous variables to explore the association between study groups and the pre-specified outcomes. Odds ratios and median differences (MD) were adjusted for: GA group (<28 weeks’ gestation or 28-31 weeks’ gestation); sex; birth weight for age z-score (<-2SD or ≥-2SD or between <2SD and ≥-2SD); exposure to antenatal steroids; NMR-2000 category (low risk, medium risk or high risk)[10]; need for mechanical ventilation on day 1; and year of admission. Any missing data for confounding variables were treated as separate categories and infants retained in the models. We used a robust variance estimator to account for clustering of infants within units. All P values were 2-sided, significance was set at P<0.05, and we used a Bonferroni correction to account for multiple testing. A predefined subgroup analysis was performed for all outcomes for infants born at <28 weeks’ gestation and those born at 28-31 weeks’ gestation.

This study was approved by Yorkshire & The Humber – Sheffield Research Ethics Committee (IRAS 259802).
Results

From the population of 63,210 infants born at <32 weeks’ gestation, 56,537 infants were retained after exclusions (Supplementary Figure 1). Of these, 45,898 infants received NIV.

Non-invasive ventilation (CPAP or HFNC) on day of birth

On the day of birth, 16,308/56,537 (28.8%) infants received NIV, which included 1,065/17,061 (6.2%) infants <28 weeks and 15,243/39,476 (38.6%) infants of 28-31 weeks’ GA. During the study period, those who received NIV on the first day increased from 1,457/6,479 (22.5%) to 2,598/7401 (35.1%). This increase was larger among the 28-31 weeks’ GA group [(from 1,357/4,570 (29.7%) to 2,471/5,194 (46.5%)] as compared to that among infants <28 weeks’ GA [from 100/1,909 (5.2%) to 181/2,216 (8.2%)].

Figure 1 shows the respiratory support received by the infants on the first day (initial respiratory support) from 2010 to 2017. The percentage receiving CPAP increased 1.3-fold from 21.5% to 28.0% whilst HFNC use increased by 7-fold from 1.0% to 7.0%. This increase was seen both in infants born at <28 weeks’ and those born at 28-31 weeks’ GA, though the magnitude of increase was greater amongst the latter (Table 1).

CPAP was used as initial support in 14,312/56,537 infants (25.3% of all admissions) of whom 18.3% (n=2,623/14,312) went on to receive mechanical ventilation within 7 days (Table 1). The failure rate was higher among infants born at <28 weeks, of whom 263/836 (31.5%) were ventilated within 7 days compared to 2,360/13,476 (17.5%) infants born at 28-31 weeks.

HFNC was used as the initial respiratory support in 1,996/56,537 infants (3.5% of all admissions). 748/1,996 (37.5%) went onto receive CPAP (n=571/1,996 [28.6%]) or mechanical ventilation (n=347/1,996 [17.4%]) within 7 days, including 170/1,996 (8.5%) who
received both CPAP and mechanical ventilation. The failure rate was higher among the more immature infants [<28 weeks’ GA: 135/229 (59.0%), including 84/229 (36.7%) who were mechanically ventilated; 28-31 weeks’ GA: 613/1,767 (34.7%), including 263/1,767 (14.9%) who were mechanically ventilated]. Among the infants who received HFNC on the first day, those who “failed” included more infants who were extremely preterm i.e. <28 weeks’ (135/784 [18.0%] vs. 94/1248 [7.5%] p<0.001); of lower birth weight [1,285 (346) g vs. 1396 (318) g; p<0.001]; multiple births (35.2% vs. 28.2%; p=0.001); born by Caesarean section (64.7% vs. 55.4%; p<0.001); had prolonged rupture of membranes (17.8% vs. 28.6%; p<0.001); and who had not had surfactant (15.0% vs. 9.5%; p<0.001). There was no difference in the sex of the infants or receipt of antenatal steroids.

**CPAP use during neonatal care**

The use of CPAP at any point during an infant’s stay in neonatal care significantly increased from 68.5% infants in 2010 (n=4,439/6,479) to 80.2% in 2017 (n=5,941/7,410) (chi-squared test for trend p<0.001). Further data on the use of CPAP in infants who received mechanical ventilation as initial respiratory support are described in Table 2.

**HFNC use during neonatal care**

The use of HFNC at any point significantly increased from 14.3% of infants in 2010 (n=928/6,479) to 68.0% in 2017 (n=5,039/7,410) (Figure 2, p<0.001). The increase in percentage of infants who received mechanical ventilation or CPAP as their initial respiratory support and then went on to receive HFNC, and data demonstrating earlier and more prolonged use of HFNC, are described in Table 2.

**Clinical outcomes associated with use of CPAP and HFNC**

There were 18,926 infants who had CPAP only and 26,936 infants who received any HFNC (Supplementary Figure 1). Infants receiving HFNC were more immature and smaller at
birth, more were exposed to antenatal steroids and received surfactant while a smaller proportion were delivered by caesarean section, were multiple births, and were less likely to be born to mothers who had prolonged rupture of membranes (Supplementary Table 2).

The outcomes are shown in Table 3 and by sub-group in Supplementary Tables 3 and 4. The odds of death before discharge were significantly higher in infants who had CPAP only compared to those who had any HFNC (aOR, 0.19 [95% CI, 0.17 to 0.22]). Infants who had CPAP only died at an earlier chronological age than those who received HFNC (median [IQR] age of death: CPAP group, 22 [10 to 39] days; HFNC group, 40 [20 to 76] days; p< 0.001) (Supplementary Figure 2). Excluding deaths before 36 weeks CGA, 3,136/18,003 (17.4%) infants who had CPAP only developed BPD compared to 12,336/26,260 (47.0%) who received any HFNC. The odds of developing BPD were significantly higher in the HFNC group (adjusted odds ratio odds ratio [aOR], 2.98 [95% CI, 2.81-3.15]). Infants who had HFNC spent significantly longer on respiratory support, had longer hospital stay, higher odds of NEC and other complications as compared to those who had CPAP only (Table 3).
Discussion

We found that, in England and Wales, there have been significant changes in the use of NIV in very preterm infants with substantial increase in use of HFNC from <15% of all infants born at <32 weeks’ gestation in 2010 to 68% in 2017, both as initial respiratory support (from 1% to 7%) and as support received later (from 15.7% to 69.8%). This is similar to the trend seen in Australia and New Zealand.[11]

Use of NIV on the day of birth has increased from 22% to 35% over the study period although, overall, only 8% of those born <28 weeks’ gestation received NIV on this day. In an Australia-New Zealand cohort (2007-2013), 29% of infants <29 weeks’ gestation received CPAP for initial respiratory support, 43% of whom required mechanical ventilation within 72 hours. [12] The overall CPAP failure rate was lower in our cohort (31%) even though we measured failure over a longer 7-day period. Systematic reviews of RCTs comparing early prophylactic CPAP with mechanical ventilation show a nearly 50% reduction in need for mechanical ventilation [13]. Our data demonstrate a more conservative use of CPAP as the initial respiratory support in England and Wales.

The Cochrane systematic review did not find any study that investigated the use of HFNC as the initial mode of respiratory support in infants <28 weeks’ gestation while other reviews reported that HFNC has higher failure rates than CPAP when used as first-line support in <28 week infants [14][15]. We found that 60% of <28 weeks’ gestation infants who received HFNC as initial support subsequently required escalation of support within 7 days, compared to 31.5% of the CPAP group. In the sub-group of infants born at 28-31 weeks’ gestation, 34.7% who received HFNC as initial mode required escalation within 7 days. This is similar to the 32.9% failure rate for HFNC among 28-31 week infants reported by Roberts et al. [16] in an RCT that was stopped early due to the high rate of HFNC treatment failure. When CPAP was used as initial mode of respiratory support, we found that 17.5% were ventilated
within 7 days, similar to the rate reported by Roberts et al. (16.1%) although they measured rates of intubation up to 72 hours only. HFNC use as the initial respiratory mode is increasing in popularity particularly in more mature infants. In a two-centre study in the UK, Zivanovic et al., found that use of HFNC without the need for CPAP as “rescue” was successful in preventing intubation in infants between 28 and 36 weeks’ gestation.[17]

Similarly, we found an increase in the use of HFNC later in neonatal care with significant increases in the number of infants who received any HFNC and the number of days on HFNC per infant. In addition, we also found that HFNC was given increasingly earlier with 12 days difference in initiation between 2010 and 2017.

We analysed the associations of these changes in practice with clinical outcomes and found higher mortality among infants who never received HFNC. Among those who survived to 36 weeks CGA, we found that the adjusted odds of BPD were significantly higher among those who received HFNC compared to those who had CPAP only. Infants in the CPAP only group died significantly earlier than those in the HFNC group. It is possible that attending clinicians did not choose HFNC for infants with more disease in the first few weeks of life. Such infants remained on mechanical ventilation or CPAP and may have died before they were considered well enough to receive HFNC. The survivors, particularly those who required prolonged respiratory support, were then more likely to receive HFNC, resulting in a higher rate of both survival and BPD amongst them. This suggests an element of confounding by indication i.e. the differences in outcome are related to the way a particular intervention is used rather than the intervention itself, which may explain some of the relationship between HFNC and death and HFNC and BPD. However, the use of HFNC may also be a step in the causal pathway [18] of BPD. The variable and unregulated distending pressure generated by HFNC may cause uncontrollable overexpansion and/or atelectasis that aggravate lung injury
leading to higher risks of BPD. Meta-analysis of RCTs, showed no difference in BPD between HFNC and CPAP use although the studies did not include many infants born at <28 weeks’ gestation [5]. Our findings are similar to previous smaller observational studies.[19]

Other important clinical outcomes such as late onset sepsis, NEC, PDA, pneumothorax, and ROP were also more frequent in babies who received HFNC. Infants who received HFNC required respiratory support for longer and received in-hospital neonatal care for longer. Prolonged need for respiratory support with HFNC has been demonstrated in meta-analyses of RCTs [5] and observational studies. [19,20]. Our study, due to its retrospective, observational design, cannot show a direct link between choice of NIV and any of the clinical outcomes we report. It has been suggested that the increased perceived patient tolerance, and ease of application and maintenance, may result in less urgency to wean leading to longer lengths of respiratory support and hospital stay [21].

Our study of 56,537 infants, limited by observational design, cannot imply a causative link between HFNC and either reduced mortality or increased BPD as highlighted by Roberts et al.[22] RCTs remain the gold-standard for demonstrating causation and clinical trials suggest that HFNC does not increase the risk of death or BPD compared to CPAP at least in the more mature population [5]. However outcomes in research trials can be superior to the same practice in clinical situations, possibly due to the greater level of control over patient selection and better adherence to treatment protocols in trial settings [23]. The worse outcomes, such as increased odds of BPD, in observational studies may be a consequence of indication creep [24] and outcomes may also vary with experience and training of practitioners. Careful patient selection and individualised application of HFNC may improve outcomes.
With a database that covers almost the entire population of England and Wales, we achieved a large sample size that enabled us to quantify the changes comprehensively and account for several confounding variables. In addition, we have accounted for multiple testing and used a robust variance estimator to account for clustering of infants within units. These make a robust observational study but do not remove the inherent limitation that associations do not imply causation.

**Conclusion**

NIV use is increasing. CPAP use increased 1.3-fold while HFNC use increased by 7-fold as respiratory support soon after birth. As more infants survive with BPD, we need clinical evidence and ongoing monitoring to ensure practice evolves in keeping with the best evidence to support the use of NIV as initial and ongoing respiratory support.

Abbreviations: CI, confidence interval; BPD, bronchopulmonary dysplasia; IVH, intraventricular haemorrhage; NEC, necrotising enterocolitis; ROP, retinopathy of prematurity; aOR, adjusted odds ratio, adjusted for gestational age <28 weeks, sex, birth weight z-score < -2, exposure to antenatal steroids, NMR-200 category, mechanical ventilation on day 1, year of admission.

a excluded infants who died before 36 weeks corrected gestational age
b missing observations: BPD, 8; Death before discharge, 17
c P<0.05 with Bonferroni correction
Figure Legends

Figure 1. Use of HFNC as the initial mode of respiratory support in infants born at <32 weeks’ gestational age in England and Wales (2010-2017)

Failure refers to escalation of respiratory support within 7 days i.e. HFNC failed refers to those infants who received HFNC as the initial mode of respiratory support but needed CPAP and/or mechanical ventilation within 7 days and CPAP failed refers to those who received CPAP as the initial mode of respiratory support but needed mechanical ventilation within 7 days. Image created by authors using STATA, version 15.1 (StataCorp, College Station, Tx)
**Figure 2.** Percentage of all infants born at <28 weeks’ gestational age and those born at 28-32 weeks’ gestational age in England and Wales (2010-2017) who received any HFNC during their neonatal care. Image created by authors using STATA, version 15.1 (StataCorp, College Station, Tx)
Observational cohort study of changing trends in non-invasive respiratory ventilation in very preterm infants and associations with clinical outcomes

Supplementary information Table 1 online only: List of variables extracted from the National Neonatal Research Database (NNRD) and the ICD-10 codes used to identify congenital anomaly exclusions and number of babies excluded and definitions of exposure and clinical outcomes

| List of variables extracted from NNRD |
|-------------------------------------|
| **Baseline Characteristics**         |
| - Gestational age was determined using the variables “GestationWeeks” and “GestationDays” |
| - Birth weight was determined using the variable “Birthweight” |
| - Female sex was determined using the variable “Gender” |
| - Multiplicity was determined using the variable “Fetus number” |
| - Any antenatal steroid given was determined using the variable “Antenatal steroids given” and “Steroids antenatal courses” |
| - Caesarean delivery was determined using the variable “Mode of delivery”, caesarean section being emergency caesarean section- not in labour, emergency caesarean section – in labour, elective section – not in labour, elective section – in labour |
| - Prolonged rupture of membranes (>18 hours) was determined using the variable “Rupture of membranes” |
| Surfactant given was determined using the variable “Surfactant given at resuscitation” and “Day surfactant given” |

| **Outcomes** |
|--------------|
| - CLD was determined using the variables “Respiratory support”, “AddedO2”, “Ventilation mode”, “NonInvasiveRespiratoryS” and “Daydateanon” |
| - Death before discharge was determined using the variables “Dateofdeath” and “Deathagemin” |
| - Composite Outcome was determined by CLD or death at 36 weeks’ gestation |
| - Sepsis was determined by use of antibiotics for \( \geq 5 \) consecutive days using the variables “drugsday” and searching for “penicillin, flucloxacillin, amoxicillin, gentamicin, metronidazole, meropenem, cephalosporin (cefotaxime, ceftazdime, cefradine, ceftriaxone) and vancomycin; determined that antibiotic was used for \( \geq 5 \) consecutive days by using the variable “dayoflife” |
| - Early sepsis was determined by the use of \( \geq 5 \) consecutive days antibiotics in the first seven days of life |
| - Late sepsis was determined by the use of \( \geq 5 \) consecutive days antibiotics after 7 days of life |
| - Medical NEC was determined by the variable “nectreatment” coded medically for \( \geq 5 \) consecutive days |
| - Surgical NEC was determined by the variable “nectreatment” coded as surgical |
| - Surgical PDA was determined using the variable “treatmentforpda” and searching for ‘ligation’ or ‘ligature’ or ‘closure of PDA/ patent ductus arteriosus’ or ‘open correction of PDA’ or ‘percutaneous transluminal prosthetic occlusion of PDA’ on “principleproceduresduringstay”, “principlediagnosisatdischarge” and “diagnosisisatadmission” |
| - IVH (Grade 3 or 4) was determined using data from cranial ultrasound variable “rightivh” and “leftivh” (looking for grade 3 and 4) and searching for ‘ivh grade 3’ and ‘ivh grade 4’ and ‘large intraventricular haemorrhage’ and ‘intraventricular haemorrhage/ parenchymal
haemorrhage’ in variables “diagnosisatadmission” and “principaldiagnosisatdischarge”
- PVL was determined using data from cranial ultrasound variable “pvl” and searching for ‘cystic periventricular leucomalacia’ and ‘pvl’ and ‘periventricular leucomalacia’ in variables “diagnosisatadmission” and “principaldiagnosisatdischarge”
- ROP was determined using variables “principleproceduresduringstay” and requiring VEGF and/or laser treatment
- Pneumothorax was determined by searching ‘pneumothorax’ in variables “diagnosisatadmission” and “principaldiagnosisatdischarge”
- Postnatal steroid was determined by the use of steroids (dexamethasone >3 days, hydrocortisone >7 days, methylprednisolone >3 days and prednisolone >7 days) using variables “drugsday” and “dayoflife”
- Invasive ventilation was determined by using variables “ventilationmode” and “respiratorysupport”
- Number of days of invasive ventilation was determined using variables “ventilationmode” and “respiratorysupport” and “dayoflife”
- Number of non-invasive ventilation days was determined using variables “respiratorysupport” and “noninvasiverespiratorysupport” and “dayoflife”
- Time to first oral feed given was determined using variables “dayenteralfeeds” and “formulaname” and “dayoflife”
- Number of days on the neonatal unit was determined using variables “dischtimeanon” and “admittimeanon”

Infants excluded due to missing information
Infants were excluded in there was missing information on gestational age (GA), birthweight or sex. Where contradictory data were recorded, the entry at the first admission was selected. Infants recorded as born at <22 weeks’ gestation, of birthweight for GA z-score >4, or < -4, standard deviations (SD), as admitted >12 hours after birth, had missing records of ≥1 days or had congenital anomalies that impact respiratory support listed below.

ICD-10 codes used to identify congenital anomaly exclusions and number of babies excluded

| ICD-10 code | Anomaly                                         | Number excludeda |
|-------------|-------------------------------------------------|------------------|

Q91 Edwards’ syndrome and Patau's syndrome 42

*Sum exceeds total number of exclusions as some infants had more than one anomaly

**Definition of exposure to non-invasive ventilation (NIV)**
From variables that record types of respiratory support received (invasive ventilation, NIV, supplemental oxygen, type of NIV), we first identified babies who received any NIV. Those who did not receive any respiratory support, had only mechanical ventilation and/or supplemental oxygen, or where information was not available to discern the type of NIV were excluded.

**HFNC group:** those who received HFNC for any length of time. Infants in the HFNC group may have received CPAP also.

**CPAP group:** those who received CPAP and had no record of receiving HFNC.

**Definition of clinical outcomes**

| Condition | Description |
|-----------|-------------|
| Bronchopulmonary dysplasia (BPD) | Infant requiring any supplementary oxygen or respiratory support at 36 weeks’ CGA (infants who died before 36 weeks were excluded) [9] |
| Death before discharge | Infant death prior to discharge from neonatal care |
| Late onset sepsis (LOS) | Recorded diagnosis with either a positive blood culture or antibiotic given for ≥5 consecutive days) after 72 hours of life |
| Necrotising enterocolitis (NEC) | Recorded diagnosis of confirmed NEC; surgical NEC (NEC treatment coded as surgical |
| Patent ductus arteriosus (PDA) | Recorded diagnosis of PDA requiring surgical closure |
| Retinopathy of prematurity (ROP) | Recorded diagnosis of ROP requiring vascular endothelial growth factor or laser treatment |
| Pneumothorax | Recorded diagnosis of pneumothorax |
| **Postnatal steroid administration** | Record of infant having received dexamethasone > 3 days, hydrocortisone > 7 days, methylprednisolone > 3 days or prednisolone > 7 days); |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| **Number of days of non-invasive ventilation** | Number of days of care where infants was recorded as having received any form of NIV |
| **Number of days of non-respiratory support** | Number of days of care where infants was recorded as having received any respiratory support |
| **Number of days spent in neonatal care** | Total number of days infant remained in neonatal care including stay in all neonatal units they were cared for in. |

*Code lists are available from the authors on request.
### Supplementary information Table 2. Characteristics of infants who received NIV with HFNC or with CPAP only from 2010 to 2017 in England and Wales, by gestational age group.

Supplementary information Figure 1. Very preterm infants who received NIV in neonatal units in England and Wales (2010-2017)

- Inclusion criteria:
  - Infants born at <32 weeks gestation
  - Between 01 Jan 2010 and 31 Dec 2017
  - Admitted to a neonatal unit in England or Wales
  - Routinely collected data in the National Neonatal Research Database

- Total number of eligible infants: n = 63,210

- Exclusions: n = 6,673 (10.6%)
  - 13 gestational age <22 weeks
  - 56 missing sex
  - 16 missing birth weight
  - 83 extreme birth weight for age z-score
  - 1,561 congenital anomalies
  - 1,676 admitted >12hrs after birth
  - 3,029 missing records for 1+ days of care

- Included infants: n = 56,537

- Infants who received non-invasive ventilation: n = 45,898

- Received HfNC: n = 26,936
  - <28 weeks gestation: n = 10,734
  - 28-31 weeks gestation: n = 16,202

- Received CPAP only: n = 18,929
  - <28 weeks gestation: n = 3,107
  - 28-31 weeks gestation: n = 15,819
Supplementary information Figure 2. Survival curve for infants born at <32 weeks’ who received any NIV during their neonatal care in England and Wales in 2010 to 2017: comparison between those who received HFNC and those who received CPAP
