Abstract

Background

Sleep problems are common among children and adolescents. Sleep quality plays a significant role in adolescents’ mental health. The study aimed to determine the prevalence of poor sleep quality (PSQ) among secondary school students, identify sociodemographic factors associated with PSQ in this group, and to examine the independent associations of psychological distress, stimulant use and internet use with PSQ.

Methods

Data were collected from 420 secondary school students from four different schools who were selected using a mixture of convenience and random sampling. A set of questionnaires was administered to collect data, and it consisted of 5 sections measuring: the sociodemographic, drug use, psychological distress, internet use, and sleep quality.

Results

A total of 378 questionnaires were analyzed. The prevalence of those with PSQ was 12.2%. A logistic regression model showed that anxiety (AOR=1.20, 95%CI:1.10-1.32), depression (AOR=1.12, 95%CI:1.00-1.25), and internet use (AOR=1.02, 95%CI:1.00-1.03) were significantly associated with PSQ.

Conclusions

PSQ commonly exists among students and has a relationship with their psychological state and potentially addictive behavior, such as internet use. A bi-directional evaluation of PSQ as a cause and, or effect of psychological and addictive problems, was further recommended.

Background

The National Sleep Foundation described good sleep quality as total sleep time of 85% or more, commencing sleep not later than half an hour while attempting sleep, waking up not more than once during the night and being able to recommence sleep within 15 minutes of an initial awakening across all age groups [1]. While sleep quantity (number of hours of sleep during the night) is an essential determinant of how "good sleep" could be defined, the quality of sleep is a more important determinant of optimal sleep as the range of sleep quantity vary widely from one individual to the other [2].

Sleep problems are common among children and adolescents in Nigeria [3, 4] and beyond [5-7], and they are associated with physical and mental health indices. For example, while poor quality of sleep is associated with obesity, impaired blood lipids in adolescents [8], reduced learning capacity, and academic performance [9]; it is also associated with psychological symptoms such as depression, anxiety disorders, and behavioral disorders in studies among adolescents [9-11].
Another association of importance is that of sleep problems and drug use. Drug use has varying effects on sleep depending on the type, amount, and stage of use, the association between sleep quality and stimulating drugs has been established, though it remains complex [12]. Stimulants such as methylphenidate have been shown to improve both quantity and quality of sleep in a population of individuals with attention deficit hyperactivity disorder, but this claim does not appear to hold among those without the disorder [13, 14]. Another survey involving 166 participants revealed that dependence on stimulants such as caffeine and nicotine was associated with poor quality of sleep and increased psychological distress [15].

Sleep problems have also been associated with internet use, another potentially addictive behavior, among adolescents and young adults [7, 16]. In a study that examined the relationship between internet use and sleep-related problems in 1212 adolescents, using the Young Internet Addiction Scale, it was observed that the adolescents who had higher scores reported more problematic sleep habits and sleep problems [17].

The relationship of sleep quality with these domains of interest: psychological distress, stimulant use, and internet use have not been adequately studied, even though there are some reports on the prevalence of poor sleep quality (PSQ) among children and adolescents in Nigeria [3, 4, 18]. Undoubtedly, there is growing evidence that the rate of drug (stimulant) use is increasing among adolescents in Nigeria [19] who use stimulants to stay alert and fend off sleep [20]. Similarly, the number of internet users and abusers among adolescents in Nigeria has continued to rise [21], and the figure of adolescents suffering from psychological problems has equally increased [22]. In a locale where data is grossly insufficient, it is apt to fill in gaps in information by conducting studies of this nature, which may be useful for other researchers, clinicians, and policymakers. With the increasing concern about students’ mental health in recent years, it is, therefore, necessary to update the prevalence of PSQ among secondary school students, identify sociodemographic factors associated with it in this group, and to examine the independent associations of psychological distress, stimulant use and internet use with PSQ.

**Methods**

**Study Location and population**

This cross-sectional study was carried out in Benin City, which is the capital city of Edo State, located in the South-South geopolitical zone of Nigeria. The city is the residence of diverse ethnic groups, and it has a population of more than a million persons. Within the city are schools either owned by the government (public) or by individuals (private). The privately-owned schools obtain approval from the government to operate, and they far outnumber the public schools. The school system is such that the secondary school education is divided into junior and senior, and each is a three-year program. The study population consisted of students from both levels of secondary schools.

**Procedure**
Ere the collection of data, approval was obtained from the research and ethics department, Edo State Ministry of Education, and the authorities of the schools involved. Written informed consent was obtained from the participants and their parents/teachers if below the age of 18 years. Only the students who could give consent or assent and understand the English language enough to fill the questionnaire were selected.

A total of 420 questionnaires were distributed even though a sample size of 195 was calculated using a Nigerian study in which 15.5% of children and adolescents had sleep problems [18]. Sampling was based on convenience; four gender-mixed schools were picked from the numerous schools in the city. The selection was purposefully made to include two schools each from the public (government-owned) and privately owned schools. Students were thereafter randomly selected from both the junior and senior secondary levels from the chosen schools.

Two research assistants who were adequately trained were employed for the collection of data. The training entailed understanding the content of the questionnaire enough to be able to assist the students when necessary. The administration of the questionnaire was done in the classroom, mostly during the break period. Data were collected between January 22 and February 2, 2018.

**Measures**

A set of questionnaires which consisted of 5 sections was used for collecting data.

*Socio-demography*

The first section, which is the sociodemographic characteristics, was used to collect information such as the gender, age, family structure, school type, religion, ethnicity, parental figure, and academic performance of the students. It was purposefully designed and structured to meet the objectives of the study.

*Sleep Quality*

The Sleep Quality Questionnaire (SQQ) [23] was used to assess sleep quality in the participants. It is a 9-item scale that is scored on a 5-point scale from 0 to 4 and added together. Possible scores range from 0 to 27; the lower the score, the more severe the sleep problem, while high scores indicate sleep to be in good shape. A score of 18 and below is highly suggestive of problems with sleep using SQQ, and this was adopted as the cut off in this study (Hungton, 2016). The scale has a strong correlation ($r=0.925$) with another sleep scale, the Sleep Condition Indicator, which has been validated and found to have good psychometric properties [23]. The reliability score of the SQQ in the current study was 0.71.

*Internet Addiction*

The Internet Addiction Test [24] is a 20-item scale that assesses the general pattern of internet use and its impact on the respondent's life at work, school, home, and social. Responses are made on a 6-point Likert
measure (0-5); thus, the possible score ranges between 0 and 100. A score of 50 and above indicates a potential internet addiction which was chosen in this study [25]. It has been widely used among students, and the scale recorded a Cronbach alpha of 0.93 in the current study.

**Psychological distress**

The Hospital Anxiety Depression Scale (HADS)[26] was used to screen for the presence of anxiety and depression in the participants. HADS can be used in clinical and non-clinical populations, and it consists of seven depression and anxiety items. It has been validated for use in Nigeria [27]. A higher score on each scale indicates increased psychological distress. A cut-off point of eight and above on either of the two components is regarded as a probable case diagnosis.

**Drug Use**

The World Health Organisation Questionnaire for Student Drug Use Surveys was developed from different parts of the world, including Nigeria [28]. For this research, only the tobacco and caffeine sections of the instrument were used to obtain information on the commonly used stimulants. Respondents are required to indicate whether they have used them in the past thirty days (current use) and the frequency of use within this period. The instrument has been used in different cultures and countries, including Nigeria.

**Data analyses**

Data collected were analyzed using the Statistical Package for Social Sciences (SPSS), version 22. Univariate analysis, such as frequencies, was determined in percentages and displayed in tables. Some variables, such as religion, current stimulant use, were dichotomized to enable a sufficient number of participants for analysis. Cut off points were utilized to determine the prevalence of cases of depression, anxiety, problematic internet use, and PSQ. However, the continuous scores of some of these variables were employed in further bi-variates and multi-variates analyses.

The Chi-square tests were used to determine the association between sleep quality and categorical variables such as gender, family structure, school type, academic performance, current use of stimulants (caffeine and cigarette). The sleep quality scores were tested for normality using the one-sample Kolmogorov-Smirnov tests and were found to be non-normally distributed. Hence, the non-parametric Mann-Whitney U test was applied to examine the differences in the rank mean scores of age, depression, anxiety, and internet use between the normal and poor group of sleep quality. Variables such as current tobacco use, internet use, depression, and anxiety, which were significant on bi-variates analyses were included in the logistic regression model. A p-value of less than 0.05 was accepted as the level of statistical significance

**Results**

**Sociodemographic characteristics**
A total of 378 (90%) out of the 420 questionnaires distributed were analyzed. The remaining questionnaires were discarded because of inconsistent responses or unfilled data. The participants comprised of 174 (46.2%) male and 203 (53.8%) female students. Age ranged between 10 and 21 years with a mean and median of 14.78 and 15.00 years, respectively. The sample included 189 students from the public schools, while 183 (49.2%) were from private. Other characteristics of the participants are summarized in Table 1.

**Prevalence of PSQ and associated variables**

The prevalence of those with PSQ was 12.2%, and those with problematic internet use measured 23.3%. Current uses of caffeine and tobacco were 39.4% and 6.1%, respectively. One hundred and twelve (29.6%) and 48.4% of the participants scored respectively above the cut-off point for the Hospital Anxiety and Depression Scale to merit cases of depression and anxiety.

A significant association was found between PSQ and current tobacco use ($p = 0.01$). (Table 2). Furthermore, participants with PSQ had significantly higher scores on anxiety scale ($p = 0.00$), depression scale ($p = 0.00$), and internet use ($p = 0.01$) when compared with those without sleep problems (Table 3).

A binary logistic regression of the current use of tobacco, internet use, depression, and anxiety was carried out on PSQ. The result showed that anxiety, depression, and internet use were significantly associated with PSQ (Table 4).

**Discussion**

We investigated the prevalence of PSQ and its interaction with some identified risk factors, which include sociodemographic and clinical correlates. Our findings revealed that 12.2% of the participants rated themselves to have PSQ. Evidence from previous studies among adolescents, such as in the USA [5], Taiwan [7], Turkey, [29] and Nigeria [3, 4] revealed higher rates, compared to the current report, which is higher than what was reported in India [30]. The disparity in rates may be related to the differences in research tools used to assess sleep quality, the definition of terms, as well as the age of the participants. For example, while the mean age of the participant in the current study is lower than those from the USA [5], Taiwan [7], Turkey, [29] and Nigeria [3, 4], it is slightly higher than the study from India which reported a lower prevalence [30]. It thus appears that increasing age is linked to higher sleep quality, having compared all these prevalence reports.

An earlier study has reported a different rate of sleep-related problems at different stages of adolescent development, with a lower rate at the early adolescence compared to late adolescence [4]. While the ranked mean age of those who reported poor quality of sleep in the present study was higher than those who did not, the difference was not statistically significant. This is similar to the report by Şimşek and Tekgül [29], who examined the effect of age on sleep quality even though a different screening tool was applied in their study. The effect of the biological changes which accompanies aging has been well acknowledged and said to account for the changes in sleep pattern in the adolescents. Notwithstanding,
evidence pointing to the role of environmental elements, especially the modern-day technology, and those of the psychological disorders, are now evolving [7, 29]. Some authors have linked the reduced need for sleep and an increasing stage of adolescence with increasing school and social demands [30, 31]. Hence, the lack of association of age with sleep quality may simply suggest that environmental and psychosocial factors that are related to maturity are more likely to account for the increasing rate of poor sleep in older age groups rather than the effect of biological development. When we attempted to explore the possible social and environmental factors which may be responsible for PSQ in our sample using chi-square tests, four factors emerged. These include the current use of tobacco, internet use, depression, and anxiety disorders.

Tobacco use has been shown to reduce the quality of sleep [32, 33], and high levels of withdrawal, and craving, have been associated with PSQ [33]. The present study revealed an association between tobacco use and PSQ, but when we included this variable in the logistic regression model, the association fizzled out. This suggests that some mediatory factors which explain the association between the two domains exist. Whilst it is necessary to further explore the relationship between tobacco use/abuse and sleep quality in a carefully selected sample, smokers should be well informed on the possible implication of smoking on sleep quality.

The rates of anxiety and depression amongst our participants are very high, as other reports from studies conducted among adolescents elsewhere [22, 34]. Our study also revealed that the participants’ sleep quality was significantly associated with these health conditions, as in other studies [10, 11]. The composite relationship between sleep and psychological disorder, such as anxiety and depression in adolescents, has attracted much attention over time [10, 35]. Although there has been mixed evidence regarding the bidirectional relationship between sleep and anxiety disorder [10], evidence supporting early sleep problems as a precursor to anxiety in adolescence is receiving a lot of attention [36-38]. Regulation of mood and emotion is contingent on adequate sleep. This is because the key neural regions and circuitry involved in emotional processing and regulation are highly active during sleep than during wakefulness [39]. In an experiment where adolescents were subjected to a mild sleep restriction protocol of 6.5 hours in bed per night for five consecutive nights, the participants were more irritable, oppositional, tense, and prone to emotional outbursts, compared with a healthy sleep duration plan [40]. Furthermore, a gradual sleep extension in adolescents experiencing a chronic reduced sleep duration was reported to significantly reduce depressive symptom severity in these individuals [41]. Early identification of sleep problems and effective interventions may be potential preventive measures for psychological disorders later in life. Conversely, poor sleep is one of the common symptoms of psychological disorders such as anxiety, depressive, and psychotic disorders [42]. Improved sleep quality is one of the earliest signs of remission of most psychological disorders, while poor quality of sleep is an early feature of relapse [42].

Our model also revealed a strong influence of internet use on sleep quality, as reported in some previous studies [7, 16]. Internet access has contributed significantly to African growth in terms of economic and health promotion, but its excessive use has been associated with unwanted health outcomes, particularly psychological, especially in youth. The scientific explanations behind the link between internet use and
poor sleep are poorly understood and beyond the scope of our study. One study has implicated the stimulating effect of the central nervous system, through participating in internet games and mind activating program at bedtime, on prolonged sleep latency [43]. Another possible theory is the suppressing effect of the blue light emission on the secretion melatonin from the pineal gland, which comes from internet-enabled devices, which may consequently result in the prolongation of sleep latency [44]. Alternatively, adolescents with sleeping difficulty may use the internet to engage themselves or cope with this problem rather than seeking professional help until they develop a medical or psychological disorder. However, the link between poor sleep and internet use should be further elucidated in African samples. In Africa, factors that encourage excessive and late-night internet use should be studied and addressed. Foremost amongst these factors is the availability of cheaper internet in the night, commonly called ‘midnight internet package.’ The typical sales advert ‘trading sleep for data,’ which encourages excessive midnight internet use should be discouraged. Perhaps, warning regarding the psychological effect of internet use at night should be attached to the advert as in the case of tobacco use.

Our study is limited in terms of generalisability to other regions in Nigeria. Also, convenience sampling applied in the study has limitations in prevalence studies. Furthermore, the analysis cannot determine the causal relationship between our outcome and the dependent variables due to its cross-sectional nature. A longitudinal study will be more applicable.

Conclusions

Our findings revealed PSQ in 12.2% of the adolescents that were sampled, and this falls towards the lower limit of the range reported elsewhere. Age, and use of stimulating drugs, were not found to predict the poor quality of sleep in our sample independently. Our study rather suggested the possible influence of psychological and environmental factors such as depression, anxiety, and internet use. We hypothesized that environmental and psychosocial factors that are age-related to maturity are more likely to account for the increasing rate of poor quality of sleep rather than the age effect of biological development. We, thus, recommend a more in-depth investigation of the interaction among these factors and sleep quality in a more carefully selected sample of adolescents. Importantly, we suggest further exploration of PSQ as a precursor of psychological disorders, as it may be one of the potential ways of preventing psychiatric disorders from developing later in life. Also, we prescribe the optimal management of psychological disorders, of which sleep problems are a typical fallout.
