Abstract

This paper is intended to: 1) show how the local smooth geometry of spaces of normal quantum states over W*-algebras (generalised spaces of density matrices) may be used to substantially enrich the description of quantum dynamics in the algebraic and path integral approaches; 2) provide a framework for construction of quantum information theories beyond quantum mechanics, such that quantum mechanical linearity holds only locally, while the nonlocal multi-user dynamics exhibits some similarity with general relativity. In the algebraic setting, we propose a method of incorporating nonlinear Poisson and relative entropic local dynamics, as well as local gauge and local source structures, into an effective description of local temporal evolution of quantum states by using fibrewise perturbations of liouvilleans in the fibre bundle of Hilbert spaces over the quantum state manifold. We apply this method to construct an algebraic generalisation of Savvidou’s action operator. In the path integral setting, motivated by the Savvidou–Anastopoulous analysis of the role of Kähler space geometry in the Isham–Linden quantum histories, we propose to incorporate local geometry by means of a generalisation of the Daubechies–Klauder coherent state phase space propagator formula. Finally, we discuss the role of Brègman relative entropy in the Jaynes–Mitchell–Favretti renormalisation scheme. Using these tools we show that: 1) the propagation of quantum particles (in Wigner’s sense) can be naturally explained as a free fall along the trajectories locally minimising the quantum relative entropy; 2) the contribution of particular trajectories to the global path integral is weighted by the local quantum entropic prior, measuring user’s lack of information; 3) the presence of nonlinear quantum control variables results in the change of the curvature of the global quantum state space; 4) the behaviour of zero-point energy under renormalisation of local entropic dynamics is maintained by local redefinition of information mass (prior), which encodes the curvature change. We conclude this work with a proposal of a new framework for nonequilibrium quantum statistical mechanics based on quantum Orlicz spaces, quantum Brègman distances and Banach Lie algebras.

1 Introduction

In this Section we will motivate the approach of this paper by discussing how it is related to the structures and problems of Kähler geometric and C*-algebraic approaches to quantum kinematics, as well as hamiltonian and path integral approaches to quantum dynamics. Our goal is to overview and explain the merits of the constructions that we pursue on the subsequent pages. The in-depth analysis of an approach to foundations of quantum theory\(^1\) that we briefly postulate and use here is provided in another paper [214].

1.1 Quantum information geometric foundations: global postulates

The basic kinematic postulates of our framework are:

- **Postulate 1:** The underlying spaces of inquiry are \( \mathcal{W} \)-algebras \( \mathcal{N} \), instead of sample spaces and Hilbert spaces.

- **Postulate 2:** The state spaces of quantified knowledge are sets \( \mathcal{M}(\mathcal{N}) \) of positive normal states on \( \mathcal{W} \)-algebras, instead of probabilistic models and spaces of density matrices.

- **Postulate 3:** The observables are arbitrary real valued functions \( f : \mathcal{M}(\mathcal{N}) \to \mathbb{R} \) of normal states, instead of arbitrary real valued functions on sample spaces and self-adjoint operators.

- **Postulate 4:** Given an experimental configuration space \( \Theta \), a method of model construction defining a mapping \( \Theta \ni \theta \mapsto \phi(\theta) \in \mathcal{M}(\mathcal{N}) \), and a choice of the set of functions \( \tilde{f} : \Theta \to \mathbb{R} \) that one is interested in, the set of observables that are relevant for a given problem is given by \( \{ f : \mathcal{M}(\mathcal{N}) \to \mathbb{R} \mid f \circ \theta = \tilde{f} \} \).

While C*-algebras\(^2\) generalise algebras of complex continuous functions on compact topological spaces, \( \mathcal{W} \)-algebras generalise \( L_\infty \) spaces over localisable boolean algebras (or, equivalently, localisable measure spaces), so the problem of choice between them depends not only on the mathematical properties of a specific application but also on the general interpretation assigned to the quantum theoretic formalism. From the mathematical perspective of general integration theory (including integration on noncommutative \( \mathcal{W} \)-algebras, on nonassociative Jordan algebras, and on spectral convex sets), it is completely natural to extend considerations from the sets of density matrices to the sub-sets of positive parts of \( \mathcal{W} \)-algebra preduals of arbitrary \( \mathcal{W} \)-algebras. The set of all (not necessarily normalised) density matrices is characterised as a positive part \( \ell_1(\mathcal{B}(H))^+ \) of a noncommutative \( \ell_1 \) space associated to the \( \mathcal{W} \)-algebra \( \mathcal{B}(H) \) of bounded linear operators on a Hilbert space \( H \) (more precisely, \( \beta \ell_1(\mathcal{B}(H)) \cong \mathcal{G}_1(H) \), where \( \mathcal{G}_1(H) \) is a Banach space of all trace class operators, equipped with a trace norm), while the Banach preduals \( \mathcal{N} \) of arbitrary \( \mathcal{W} \)-algebras \( \mathcal{N} \) are characterised as a noncommutative \( L_1 \) spaces associated to these algebras, and this association is functorial with respect to \( \mathcal{W} \)-isomorphisms [99]. Hence, if one considers quantum mechanics and probability theory as two instances of a more general class of information theories, then the use of \( \mathcal{W} \)-algebras \( \mathcal{N} \) and elements of \( L_1(\mathcal{N})^+ \cong \mathcal{N}^+ \) for the mathematical foundations of quantum mechanics is a natural and exact generalisation of mathematical formulation of probability theory in terms of a normalised measure theory.

---

\(^1\)We distinguish between the quantum mechanics, understood as a framework defined in [361], and the quantum theory, understood as a (currently unknown) framework that should be capable of providing mathematically exact nonperturbative foundations for relativistic quantum field theory and nonequilibrium quantum statistical mechanics.

\(^2\)A C*-algebra is defined as an algebra \( \mathcal{C} \) over \( \mathbb{C} \), equipped with: an operation \( * : \mathcal{C} \to \mathcal{C} \) that algebraically abstracts the properties of a complex conjugation of complex numbers, and a norm \( \| \cdot \| : \mathcal{C} \to \mathbb{R}^+ \) that turns \( \mathcal{C} \) into a Banach space satisfying \( \| \alpha x \| = \| x \| \forall x \in \mathcal{C} \). \( \mathcal{W} \)-algebras are characterised as such C*-algebras for which there exists a Banach space, denoted \( \mathcal{L} \), and called a (Banach) predual, satisfying \( (\mathcal{C}, \cdot)^* \cong \mathcal{C} \). Given a Banach space \( X \) over \( \mathbb{C} \), the operation \( \cdot : X \to X^* \) forms a Banach space of all continuous linear \( \mathbb{C} \)-valued functionals, equipped with a supremum norm.
(as proposed by Steinhaus [334] and developed by Kolmogorov [200]). This leads us: 1) to choose the framework of $W^{*}$-algebras $\mathcal{N}$ and normal positive states $\omega \in \mathcal{N}_+^*$ instead the framework of $C^{*}$-algebras $C$ and positive states $\omega \in C_+^*$; 2) to consider subsets $\mathcal{M}(\mathcal{N}) \subseteq \mathcal{N}_+^*$ as spaces of quantum states that are setting the arena for quantum kinematics. We view them as natural generalisation of probabilistic models $\mathcal{M}(\mathcal{X}, \mathfrak{U}(\mathcal{X}), \mu) \subseteq L_1(\mathcal{X}, \mathfrak{U}(\mathcal{X}), \mu)^+$. The observables in our framework are defined as arbitrary real valued functions $f : \mathcal{M}(\mathcal{N}) \rightarrow \mathbb{R}$. The observables in the standard sense of quantum mechanics are precisely determined as an affine subset of the observables in our sense:

$$f_x(\phi) := \phi(x) \quad \forall x \in \mathcal{N}^{sa} \quad \forall \phi \in \mathcal{N}_+^*.$$  \hspace{1cm} (1)

Postulates 1-4 do not yet determine how we are going to define specific kinematic and dynamic models. Following Chencov's geometric approach to foundations of statistical inference theory [53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 244] (developed later by Amari and others [4, 5, 6, 7, 8, 9]), Jaynes information theoretic approach to foundations of statistical mechanics [166, 167, 168, 179, 169, 170, 172, 174, 175, 177] (developed later in the geometric direction by Ingarden and others [150, 156, 151, 152, 158, 153, 154, 155, 157]), and the program of smooth geosmetricisation of quantum mechanics [344, 236, 191, 69, 326, 68, 142, 264, 2, 10, 70, 111, 71, 147, 148, 299, 102, 103, 45, 21, 67, 46, 65, 29], we propose the following

- **Postulate 5**: The construction of specific models of kinematics and dynamics is based upon the geometric structures over state spaces, provided by quantum relative entropies and Banach Lie algebras, instead of scalar product of Hilbert space.

In order to investigate the possible generalisations of quantum mechanical prescriptions of dynamics we want first to understand the geometric structures on state spaces. For a given Hilbert space $\mathcal{H}$ equipped with a scalar product $\langle \cdot, \cdot \rangle_{\mathcal{H}} : \mathcal{H} \times \mathcal{H} \rightarrow \mathbb{C}$, the projection $\mathbb{P} : \mathcal{H} \setminus \{0\} \ni \xi \mapsto \frac{\xi}{||\xi||_\mathcal{H}} \in \mathcal{P}\mathcal{H}$ induces a manifold structure on $\mathcal{P}\mathcal{H}$, with tangent spaces given by $\mathcal{H}$, riemannian metric $g^\mathcal{H}$ and symplectic form $w^\mathcal{H}$ determined uniquely by a decomposition [1]

$$\langle \cdot, \cdot \rangle_{\mathcal{H}} = \frac{1}{2} g^\mathcal{H}(\cdot, \cdot) + \frac{1}{2} w^\mathcal{H}(\cdot, \cdot),$$  \hspace{1cm} (2)

and complex structure defined by $\langle \cdot, j^\mathcal{H}(\cdot) \rangle_{\mathcal{H}} = i \langle \cdot, \cdot \rangle_{\mathcal{H}}$. The tangent bundle of $\mathcal{H}$ over $\mathcal{P}\mathcal{H}$ can be viewed as a principal $U(1)$-bundle equipped with a $U(1)$ connection 1-form $\nabla^p : \mathcal{H} \times \mathcal{H} \ni (\xi, \zeta) \mapsto i \langle \xi, d\zeta \rangle_{\mathcal{H}} \in \mathbb{C}$. In our case, the lack of a unique global Hilbert space implies the lack of unique specification of riemannian metric and symplectic form derived from a scalar product. In order to facilitate a well-defined generalisation of riemannian and symplectic structure, the sets $\mathcal{M}(\mathcal{N})$ can be equipped with two different smooth real Banach manifold structures. On one hand, an information manifold structure on state spaces. For a given Hilbert space $\mathcal{H}$, the coadjoint action of $\mathcal{H}$ is a real Banach submanifold $\mathcal{B}$ of all self-adjoint elements of a $W^{*}$-algebra $\mathcal{N}$, and has tangent spaces defined as copies of a Hilbert space $\mathcal{B}$ becomes recovered as an extension to the boundary of pure states for a wide class of geometries $(\mathcal{M}(\mathcal{N}), g^D, \nabla^D, (\nabla^D)^\dagger)$. The Fubini–Study riemannian metric $g^\mathcal{H}$ becomes recovered as an extension to the boundary of pure states for a wide class of geometries $(\mathcal{M}(\mathcal{N}), g^D)$ [272]. On the other hand, given the choice of a Banach–Lie algebra $\mathcal{B}$ such that $\mathcal{M}(\mathcal{N})$ is a real Banach submanifold $\mathcal{B}$, with $T_\phi \mathcal{B} \cong \mathcal{B}, \forall \phi \in \mathcal{B}$, (or, more generally, $ad^*_x(\mathcal{B}) \subseteq \mathcal{B}, \forall x \in \mathcal{B}$), the coadjoint action of $\mathcal{B}$ on $\mathcal{B}$ induces a Poisson structure on Fréchet smooth

\footnote{For a discussion why an injective immersion of $\mathcal{M}(\mathcal{N})$ into $\mathcal{B}$, is not sufficient, see [39].}
real valued functions on \(\mathcal{M}(\mathcal{N})\). If \(\mathcal{B}\) is a Lie algebra of a group \(G\), then the Banach Lie–Poisson manifolds \(\mathcal{M}(\mathcal{N})\) are symplectic if they are coadjoint orbits of \(G\). In particular, if \(\mathcal{B} \cong \mathcal{N}\text{sa} \cong \mathcal{N}\text{uni}\) (a group of all unitary elements of \(\mathcal{N}\)), and \(\mathcal{B}_\bullet \cong \mathcal{N}\text{sa}_\bullet := \{\phi \in \mathcal{N}_\bullet \mid \phi(x^*) = \phi(x)^*\} \cong (\mathcal{N}\text{sa})_\bullet\). The example of such case is given by the orbit of a group of unitary operators of density matrices with finite fixed number \(n \in \mathbb{N}\) of nonzero eigenvalues \([38]\). For \(n = 1\), one recovers precisely the symplectic structure \(\mathbf{w}^H\) on a projective Hilbert space \(\mathbb{P}\mathcal{H}\) that is induced from \(\langle \cdot, \cdot \rangle_H\) on \(\mathcal{H}\) \([36]\).

The resulting description of quantum geometry can be summarised as follows:

(a) In the general setting of \(\mathcal{W}^\ast\)-algebras \(\mathcal{N}\) and quantum states defined as elements of \(\mathcal{N}_\bullet^+\) the smooth manifold structure required to implement the infinite-dimensional quantum generalisation of Poisson geometry does not match with the smooth manifold structure required to implement the infinite-dimensional quantum generalisation of riemannian geometry (this issue is discussed in more details in \([214]\)). As a result, the geometry of a Hilbert space \(\mathcal{H}\) (consisting of pure states), formulated in terms of riemannian metric \(\mathbf{g}^\mathcal{H}\) and symplectic structure \(\mathbf{w}^\mathcal{H}\) defined over the same real Hilbert smooth manifold \(\mathbb{P}\mathcal{H}\), becomes generalised to the geometry of spaces \(\mathcal{M}(\mathcal{N})\) equipped with two different real Banach smooth manifold structures: of a Banach Lie–Poisson manifold and of a quantum information geometric (relative entropic) manifold. The former is determined by the choice of a Banach Lie algebra \(\mathcal{B}\), and in the special cases reduces to a symplectic space. The latter is determined by the choice of a relative entropy functional \(D : \mathcal{M}(\mathcal{N}) \times \mathcal{M}(\mathcal{N}) \rightarrow [0, \infty]\), and in the special cases reduces to a torsion free Norden–Sen manifold, or just a riemannian space.

(b) Apart from the above two alternative systems of tangent, cotangent, and higher jet bundles, one can also introduce a bundle of Hilbert spaces over \(\mathcal{M}(\mathcal{N}) \subseteq \mathcal{N}_\bullet^+\), that can serve as as an ambient framework to represent different geometrical objects. A natural candidate is a Gel’fand–Naïmark–Segal bundle \(\mathcal{H}\mathcal{M}(\mathcal{N})\) of Hilbert spaces \([256]\). Because the bundle \(\mathcal{H}\mathcal{M}(\mathcal{N})\) is defined by states of an underlying manifold (as opposed to a projection \(\mathbb{P}\)), there is no \(\nabla^\mathbb{P}\) connection \(U(1)\) action in fibers. However, for \(\mathcal{M}(\mathcal{N}) \subseteq \mathcal{N}_\bullet^+\), each fibre of \(\mathcal{H}\mathcal{M}(\mathcal{N})\) bundle is equipped with a strongly continuous \(U(1)\) action of a modular (Tomita–Takesaki) automorphism \(\sigma^\omega : \mathbb{R} \ni t \mapsto \text{Ad}(\Delta^\omega_t) \in \text{Aut}(\pi_\omega(\mathcal{N}))\). We will study the role of this automorphism in Section 4.5, showing that it resembles some interesting similarities with \(\nabla^\mathbb{P}\) when considered over a trajectory \(\mathbb{R} \rightarrow \mathcal{M}(\mathcal{N}) \subseteq \mathcal{N}_\bullet^+\). Yet, in Section 2.4.2 we will show that, for any \(\mathcal{M}(\mathcal{N}) \subseteq \mathcal{N}_\bullet^+\), the bundle \(\mathcal{H}\mathcal{M}(\mathcal{N})\) carries a natural connection structure, with parallel transport given by the standard unitary transition operators \(V_{\phi,\omega} := J_{\phi,\omega}J_{\phi,\omega}\), where \(J_{\phi,\omega}\) is a relative modular conjugation between two faithful normal GNS representations, while \(J_{\phi,\psi}\) is a Tomita modular conjugation. We observe that this connection is Levi-Civita with respect to the Wigner–Yanase riemannian metric, and its local geodesic free fall corresponds to constrained minimisation of the Hilbert space norm (projective measurement).

(c) Because two manifold structures mentioned in (a) do not coincide, there seems to be no obvious candidate for a ‘complex structure’ on a general quantum model \(\mathcal{M}(\mathcal{N})\). However, we notice that the use of complex Hilbert spaces of dimension \(n\) instead of real Hilbert spaces of dimension \(2n\) is crucially associated with the requirement that the generators of unitary transformations of these spaces should be represented by self-adjoint operators (identified with observables). Observing further that the standard quantum mechanical method of defining relevant observables proceeds by representations of Lie algebra \(\mathfrak{g}\) of Lie group \(G\) on the complex Hilbert space, we introduce the structure of a principal \(G\)-bundle \(E\) over \(\mathcal{M}(\mathcal{N})\), equipped with a family of representations of an associated Lie algebra in the fibers of the GNS Hilbert space bundle \(\mathcal{H}\mathcal{M}(\mathcal{N})\). This leads to a rise of a \(g\)-valued connection form on \(E\), and a fiberwise family of its representations on the fibers of \(\mathcal{H}\mathcal{M}(\mathcal{N})\). This structure exhibits some interesting features of the relationship between Berry connection, complex structure of a Hilbert space, and construction of observables by means of representations of Lie algebras. The bundle structures of \(E\) and \(\mathcal{H}\mathcal{M}(\mathcal{N})\) do not require \(\mathcal{M}(\mathcal{N})\) to be a Banach smooth manifold, but they require it to be a (Hausdorff and paracompact) topological space. We do not assume any \textit{a priori} relationship between the geometries of local
causal dynamics, as provided by $\mathcal{B}$, and the transformations used to identify locally the relevant observables, as provided by $\mathbf{g}$, because we consider it to be a model-dependent feature.

(d) Using the $\mathbf{g}$-valued connection $\nabla^\mathbf{g}$, we can define a kinematic propagator (in Prugovečki sense) of the particles (in Wigner sense) as the holonomy of $\nabla^\mathbf{g}$ along the geodesics of $\nabla^D$ (or $(\nabla^D)^\dagger$ or $\nabla^\mathbf{g}^D$) affine connection.

(e) In Section 2.4.4 we propose a construction of what we call the Morozova–Chencov–Petz Hilbert space bundle $\mathcal{H}^\mathcal{M}(\mathcal{N})$. Its purpose is to use the riemannian metrics $\mathbf{g}^D$, associated with a class $D_f$ of quantum distances, in order to determine Hilbert spaces and corresponding representations that are different from the GNS construction, and include the information about the local riemannian geometry of a model (this is inspired by the ideas of [346, 292, 291]). In principle, it can be used as an alternative to $\mathcal{H}\mathcal{M}(\mathcal{N})$ (especially for the purpose of the tasks (c)-(d)), however it is essentially harder to deal with mathematically. We consider this as an indication that the natural framework for a simultaneous implementation of geometric and algebraic tools used in this paper (entropic Norden–Sen geometries, Banach Lie–Poisson structure, perturbations of liouvilleans) are Banach dual pairs of noncommutative Orlicz spaces, used as tangent and cotangent spaces. However, the technical implementation of this idea requires one to develop a standard construction of Orlicz spaces for any (countably finite) $W^\ast$-algebra, understood as a BLP space [36, 38, 253]. Derivation of Lüders’ rules (selective and nonselective) as a special case of constrained quantum relative entropy minimisation, as opposed to a (linear) projection in a Hilbert space or Lüders’ rule.

Hence, the basic dynamical setting of quantum mechanical evolution of quantum states, which is a unitary evolution followed by a projective measurement can be completely recovered as a special case of a causal inference instrument given by the map

$$\mathcal{M}_1(\mathcal{N}) \ni \phi \rightarrow \mathcal{P}^D_Q \circ u^B_T(\phi) \in \mathcal{M}_2(\mathcal{N}),$$

where

$$\mathcal{P}^D_Q(\psi) := \arg \inf_{\psi \in \mathcal{Q}} \{D(\omega, \psi)\}.$$

With all these tools on the stage, we can approach the problem of construction of quantum dynamics.

• **Postulate 6:** The elementary form of causal dynamics is given by a Poisson flow generated by a smooth observable on a state space, as opposed to a unitary evolution on a Hilbert space. The elementary form of inferential dynamics is given by a (nonlinear) constrained quantum relative entropy minimisation, as opposed to a (linear) projection in a Hilbert space or Lüders’ rule.

Unitary evolution is a special case of a hamiltonian evolution on the self-adjoint part of a predual of a $W^\ast$-algebra, understood as a BLP space [36, 38, 253]. Derivation of Lüders’ rules (selective and nonselective) as a special case of constrained quantum relative entropy minimisation (in short: entropic projection) for $D$ given by the Umegaki–Araki distance (123) was provided in [139] and [211].

Hence, the basic dynamical setting of quantum mechanical evolution of quantum states, which is a unitary evolution followed by a projective measurement can be completely recovered as a special case of a causal inference instrument given by the map

$$\mathcal{M}_1(\mathcal{N}) \ni \phi \rightarrow \mathcal{P}^D_Q \circ u^B_T(\phi) \in \mathcal{M}_2(\mathcal{N}),$$

where

$$\mathcal{P}^D_Q(\psi) := \arg \inf_{\psi \in \mathcal{Q}} \{D(\omega, \psi)\}.$$
is an entropic projection onto constrained set $Q$ for a quantum distance functional $D$, while $\psi_t^{B,h}$ is a Poisson flow generated by a Banach Lie algebra $B$ and a Hamiltonian function $h$ for a time range $[0,t]$, corresponding uniquely to an integral line of a vector field

$$\mathcal{X}_h(\phi) := -\text{ad}_{\mathfrak{D}_\phi h}(\phi) \quad \forall \phi \in B,$$

where $\mathfrak{D}_\phi h$ is a Fréchet derivative of $h$ at $\phi$, implementing the differential form $dh(\phi)$.

In [245] it was shown that partial trace is also a special case of entropic projection. Hence, all linear completely positive maps can be considered as a special case of the maps formed by composition of tensor products, Poisson flows, and entropic projections [215, 214]. This way the kinematic and dynamic setting of quantum mechanics and nonrelativistic quantum information theory becomes fully recovered as a special case of the framework specified by Postulates 1-6 above.

This leads us to:

- **Open problem:** Reconstruct (some aspects of) dynamics of quantum field theory and nonequilibrium quantum statistical mechanics using the framework specified by Postulates 1-6.

Unlike in quantum mechanics, the dynamics of both these theories is sensitive to local geometric features of the kinematic structure of a quantum model. In consequence, we are lead to investigate how, and to what extent, the above geometric structures, and the corresponding nonlinear dynamical maps, can give account of the local structures in QFT and NQSM.

### 1.2 Local quantum information dynamics in algebraic and path integral approaches

The main questions underlying the constructions carried on in this paper are: what if the correct setting for bridging the gap between algebraic and path integral setting is to use quantum state spaces and their geometry:

1) to define local evolution in the algebraic approach by means of *locally* defined and perturbed Liouvilleans?

2) *instead* of using phase space geometry in the continuous time coherent state path integral “quantisation”?

3) to describe renormalisation as purely information theoretic procedure?

The discussion below is intended to show that the proposal of the geometric framework for locally quantum information theories that we provide in Section 1.5 is remarkably grounded in the insights coming from *three* very distinct theoretical frameworks: 1) a geometric extension of algebraic Hamiltonian dynamics with local gauge and local sources by means of local perturbation of Liouvilleans; 2) a generalisation of the Daubechies–Klauder path integration to an algebraic setting; 3) a geometric Jaynes–Mitchell–Favretti renormalisation, applicable in nonequilibrium quantum statistical mechanics.

The standard Haag–Kastler [128, 127] setting of an algebraic approach to quantum field theory is widely considered as being unable to incorporate the local gauge principle\(^7\) (the global gauge principle has been partially incorporated to an algebraic approach by means of the Doplicher–Haag–Roberts theory [85, 86]). Apart from renormalisation techniques, this principle is a fundamental tool in the construction of the predictively sound models in quantum field theory. Its maintenance by the Lagrangean/path-integral approach leads to an abandonment of the algebraic approach by most of the practitioners of QFT, but this is provided at the price of replacing mathematically well-defined objects by symbolic (and usually perturbative) techniques of calculations. This makes QFT very different from quantum mechanics, because the latter facilitates construction of predictive models without the expense of mathematical precision. In this paper we intend to show that the consideration of geometric structures on the spaces $\mathcal{N}^+_*\mathcal{W}$ of normal states over $\mathcal{W}$-algebras $\mathcal{N}$, as well as construction of

---

\(^7\)E.g. «The Lagrangean and the Feynman path integral are at present indispensable tools in the characterization and study of a specific theory. Together with the local gauge principle they pose questions which in the algebraic approach are not understood and should be tackled.» [127].
effective local dynamics by means of local perturbations of liouvilleans, may provide an extension of an algebraic approach capable of dealing with the local gauge principle and the use of ‘external sources’, typical in the path integral formalism. Our point of departure from the Haag–Kastler perspective is to consider locality in the Prugovečki sense [281], being associated with the fiber at a given point of an underlying space (so the Lorentz or Poincaré covariance condition is to be applied fiberwisely), as opposed to a neighbourhood of this point (e.g. as given by the special relativistic diamond). This allows to think of local GNS Hilbert space associated to the manifold of quantum states as (a model of, or as a container of) local tangent space, corresponding to a local quantum mechanical description provided by a single (quantum bayesian) user. Further extension from the bundle of (self-dual) Hilbert spaces to the bundle of dual pairs of noncommutative Orlicz spaces is necessary to allow the geometry of local quantum inference to be governed by a wide class of conventions of estimation, beyond the Wigner–Yanase riemannian metric (so that the quantum nonequilibrium thermodynamic Kubo–Mori–Bogolyubov metric, as well as the quantum estimation theoretic Helstrom–Uhlmann–Bures metric can be included on the equivalent mathematical footing). The construction of an underlying manifold structure commits to the principle of equivalence between local inference by means of constrained maximisation of relative entropy, and the free fall along the geodesics of the dually flat local geometry, derived from this entropy.

On the path integral side, our approach is directly inspired by the Daubechies–Klauder [77, 194, 195, 199, 35, 198] continuous-time regularised coherent state phase space approach to path integration, and the closely related Anastopoulos–Savvidou [11, 12, 13] analysis of decoherence functional in the Isham–Linden quantum histories approach. Both have shown that one can think of the underlying dynamical objects of respective theories (path integrals and decoherence functionals) as consisting of the hamiltonian evolution perturbed by the geometric structures on the space of quantum states. Our goal here is to follow Klauder’s remark «If there is ever any hope to define path integrals rigorously as path integrals over a set of paths (functions of time), then it is essential to give up the notion that the paths involved are sharp value paths and replace that with another interpretation of which the expectation value paths is a completely satisfactory example» [197] by extending these approaches to the state spaces over $W^*$-algebras, and relating them with the local liouvillean approach to algebraic dynamics. The virtue of the Daubechies–Klauder approach is that it provides a mathematically rigourous continuous time regularisation of the functional integral in a way that gives the same results under arbitrary canonical transformations of the underlying phase space. This is not true for most of other approaches to quantisation, not only path integral based. The restrictions on the class of hamiltonians that are allowed in order to maintain this procedure to be well defined are quite mild.

The key ingredient of this approach is introducing a regulariser that represents a riemannian metric on the phase space (corresponding to a Fubini–Study metric on coherent quantum states), and determines a pinned Wiener measure of the Brownian process on the phase space.

The heuristic ideas underlying our treatment of quantum dynamics are: 1) Quantum kinematics and dynamics should be defined without recourse to classical models and their quantisation; 2) Classical (phase space, but also space-time) geometry should be considered as a locally emergent feature describing particular properties of the multi-agent information processing systems and not as a fundamental structure (background); 3) Local spatial (phase space or space-time) variables should arise as epistemic (e.g. operational) parameters of information states (see e.g. [289, 90]). This heuristics is in a disagreement with the perspectives of the orthodox algebraic and path integral approaches (yet, there are some exceptions⁸), however we consider this disagreement as a virtue, because it allows us to learn something new.⁹

The main mathematical tools used in what follows are: the Hilbert space bundle over $\mathcal{N}^+_\ast$ arising from the Gel’fand–Na˘ımark–Segal representation, introduced recently by Odzijewicz and Sliżewska

⁸In particular, «the interpretation of the formal path integral (...) in terms of paths $p(t)$ and $q(t)$ for which the meaning of the variables is that of expectation values is far more acceptable than the one in which the meaning is that of both sharp position and sharp momentum (eigen)values. (...) One is almost tempted to assert that the usual interpretation in terms of sharp eigenvalues is “wrong”, because it cannot be consistently maintained, while the interpretation in terms of [expectation] values is “right”, because it can be consistently maintained» [196].

⁹See [205, 206, 207, 208] for some wi(l)der heuristic ideas that have lead to the current work.
Section 2.3 provides an elementary analysis of the relationship between W*-dynamical systems, hamiltonian flows on BLP spaces, and standard liouvilleans of the W*-dynamical systems $(\mathcal{N}, \mathbb{R}, \alpha)$. In order to study the relationship of the BLP structure with the usual usage of standard liouvilleans, we begin with characterisation of the class of weakly-continuous representations $\alpha : \mathbb{R} \to \text{Aut}(\mathcal{N})$ whose preualised actions on $\mathcal{N}_\mathbb{R}^{\text{sa}}$ can be described as Poisson flows of some hamiltonian vector field.

Our main conclusion from this analysis is that the relationship between Poisson flows and standard liouvilleans should be localised: instead of requiring a Poisson flow to globally agree with a family of norm continuous isometries arising from a predetermined W*-dynamical system, we can start from a quantum Poisson system (defined as a set $\mathcal{M}(\mathcal{N}) \subseteq \mathcal{N}_\mathbb{R}^{\text{sa}}$ equipped with some Banach Lie–Poisson manifold structure, not necessarily determined by the coadjoint action of the Lie algebra of self-adjoint elements of $\mathcal{N}$), and determine a fiberwise family of local W*-dynamical systems generated by a 1-form corresponding to a hamiltonian vector field on the state space. This way we consider the fiberwise family of local standard liouvilleans as a Hilbert space/algebraic counterpart of the smooth manifold/geometric hamiltonian vector field of the Poisson flow.

The main technique used in Section 3 is: 1) to represent a (possibly, nonlinear) local Poisson flow on the state space manifold in each fibre of the GNS Hilbert space bundle by constructing a local standard liouvillean, generating unitary evolution uniquely corresponding to the hamiltonian vector field of this flow, and then: 2) to perturb it using objects that represent additional geometric structures on the state space. The resulting structure is shown to determine a nonlinear instrument on $\mathcal{N}_\mathbb{R}^{\text{sa}}$ (in the sense of [78]), which we call a local liouvillean instrument. It describes the temporal evolution of quantum states determined by the postulated ‘internal’ dynamics (a W*-dynamical system, a Poisson flow, or a globally defined vector field) perturbed by the geometric structures on the quantum model. In other words, the local liouvillean instrument encodes the effective dynamics, that takes into account a nontrivial geometry of the space of quantum states. In addition, we discuss the possible expressions for time dependent $n$-point correlation functions that can be constructed using the above structures. Both local liouvillean instruments and correlation functions are understood as tools as quantification of the effective dynamics.

Noticing that both the GNS bundle and the tangent bundle of the manifold of quantum states can allow in principle for introduction of a nontrivial action of some Lie group $G$ on fibres, we propose to consider a specific relationship between local gauge (principal $G$-bundle connection) structure and the GNS bundle. We begin with incorporation of the (fiberwise representation of the) action of the nontrivial gauge connection $A$ (one-form valued in the Lie algebra $\mathfrak{g}$ of $G$) into the perturbation of

---

10By the Haagerup theorem [130] for standard representations of W*-algebras, for every pair of a W*-dynamical system $(\mathcal{N}, \mathbb{R}, \alpha)$ and a standard representation $(\mathcal{H}, \pi, J, \mathcal{H}^\mathfrak{g})$ of a W*-algebra $\mathcal{N}$, there exists a unique unitary evolution on $\mathcal{H}$ that represents $\alpha$ leaving $\mathcal{H}^\mathfrak{g}$ unchanged. Its generator is an unbounded operator, called the standard liouvillean.
the local liouvillean, discussing also the possible relationship between affine connection on the tangent bundle of the quantum manifold and propagation of quantum particles (in Wigner sense) in the GNS fibre bundle.

Apart from the gauge connection, we study also the class of objects that, from the perspective of the BLP structure, could be considered as nonlinear quantum fields. These are introduced as the additional source/sink terms, representing the Lie algebra valued differential one-forms on the base quantum manifold. (The idea of using source-based approach is inspired by Schwinger’s [309, 310] and the Mitchell–Jaynes [241, 177] approaches.)

As a result, we construct a setting that allows to define various nonlinear quantum models equipped with smooth geometric structures that can be represented directly in terms of the families of operators acting locally on the fibres of the GNS bundle of Hilbert spaces over the model. It seems that this framework covers quite well some of the components of the lagrangean framework (under nonorthodox assumption that space-time/phase space geometry is emergent from the geometry of quantum state spaces). The investigated correspondences between geometric and algebraic structures can be briefly summarised as:

\[
\begin{array}{c|c|c}
\text{C}^\infty\text{-geometric} & \text{GNS-bundle-algebraic} \\
\hline
\text{principal } G\text{-bundle sections} & \text{gauge propagators} \\
\text{one-forms} & \text{local quantum field source operators} \\
\text{Lie algebra valued one-forms} & \text{local gauge quantum fields} \\
\text{global charges} & \text{global source strengths}
\end{array}
\]

Under some additional conditions we can establish also some relationships between structures of tangent and the GNS bundles:

\[
\begin{array}{c|c|c}
\text{C}^\infty\text{-geometric} & \text{GNS-bundle-algebraic} & \text{extra condition} \\
\hline
\text{hamiltonian vector fields} & \text{standard liouvilleans} & \text{(PC}_2\text{)} \\
\text{geodesic trajectories} & \text{gauge geodesic propagations} & \text{(QP}_1\text{)}
\end{array}
\]

There is also a correspondence between the local liouvillean instruments acting on \( M(\mathcal{N}) \) and local liouvillean operators acting on the fibres of the GNS bundle. These instruments might be nonsmooth. Two main ideas regarding the local quantum dynamics contained in Section 3 can be summarised as:

\[
\begin{align*}
\text{local gauge dynamics} &= \text{local Poisson dynamics} + \mathbf{A}\text{-propagation}, \\
\text{local liouvillean dynamics} &= \text{local Poisson dynamics} + \mathbf{A}\text{-propagation} + \text{action of sources}.
\end{align*}
\]

An especially interesting possibility for introducing an affine connection \( \nabla \) on a tangent bundle \( T M(\mathcal{N}) \) is a third order Taylor expansion of a quantum relative entropy functional \( D \). In such case the gauge geodesic propagation of quantum particles can be carried precisely along the lines of local information flow, defined by a constrained maximisation of a relative entropy, and equivalent to the local \( \nabla^D \)-geodesic free fall. This particular application shows a virtue of using the Hilbert space bundle combined with the technique of local perturbation of standard liouvilleans: it allows to accommodate different smooth manifold structures on the space of quantum states into a single fiber-wise operator formulation. See [214] for further discussion.

In Section 4.5 we provide another example of application of this technique, constructing an algebraic generalisation of Savvidou’s action operator. It is specified by perturbation of a standard liouvillean \( L_\alpha \) of a weak-* continuous *-automorphism \( \alpha : \mathbb{R} \to \text{Aut}(\mathcal{N}) \) of a \( \mathcal{W}^* \)-algebra \( \mathcal{N} \) by the generator \( K_\omega := -\log \Delta_\omega \) of the Tomita–Takesaki modular automorphism \( \sigma^\omega : \mathbb{R} \to \text{Aut}(\mathcal{N}) \). This can be tentatively interpreted as incorporation of an action of a \( U(1) \)-connection on a fibre bundle of Hilbert spaces over a real line of a trajectory of \( \alpha \) on \( \mathcal{N}^* \). For any \( \mathcal{W}^* \)-algebra \( \mathcal{N} \), the Falcone–Takesaki theory [99] functorially associates a ‘core’ von Neumann algebra \( \widetilde{\mathcal{N}} \). If \( \mathcal{N} \) is equipped with a faithful normal algebraic state \( \omega \), then there exists a canonical unitary isomorphism \( \widetilde{\mathcal{N}} \cong \mathcal{N} \rtimes_{\sigma^\omega} \mathbb{R} \) with the crossed product corresponding to a \( \mathcal{W}^* \)-dynamical system \((\mathcal{N}, \mathbb{R}, \sigma^\omega)\) formed by a modular *-automorphism \( \sigma^\omega \) of \( \mathcal{N} \). This crossed product is a von Neumann algebra generated by the operators \( \pi_{\sigma^\omega}(x) \) and \( u_\mathbb{R}(t) = e^{-it\widetilde{V}} \) acting on the space \( \mathcal{H}_\omega \otimes L_2(\mathbb{R}, dt) \) by means of the equations (290) and (291). The
covariance equation (294), where a self-adjoint linear operator $K_\omega$ is equal to the Tomita–Takesaki modular hamiltonian, turns the ‘Liouville’ (in Savvidou’s sense) action of $e^{-it\hat{V}}$ on $L_2(\mathbb{R}, dt)$ into the action of $e^{-itK_\omega}$ on the space $\mathcal{H}_\omega$. Hence, one can say that it ‘internalises the description of external unitary kinematics’. The perturbed operator $L_\alpha + K_\omega = L_\alpha - \log \Delta_\omega$ provides an algebraic replacement of the quantum histories description of action operator given by equations (239) and (238).

### 1.2.2 Local information geometry in quantum histories

By analysis of the virtues and drawbacks of the above formulation of an algebraic action operator, we come to a conclusion that the proper candidate for a description of the geometric perturbation of a dynamics due to the local change of state in a projective measurement is not $K_\omega$, but a standard unitary transition operator $V_{\phi,\omega}$ (which is not easily incorporable into the local liouvillian framework). It is a parallel transport of the Levi-Civita connection $\nabla^{1/2}$ of the Wigner–Yanase metric $g^{1/2}$, and projections along its “free fall” geodesics are equal to the linear projections in a (standard representation) Hilbert space. This observation leads us to revisit the use of a Fubini–Studyn metric $g^{FS}$ on the space of coherent states (which coincides, up to a multiplicative scalar factor $4$, with $g^{1/2}$, when the latter is extended to the boundary of the pure states) for the purposes of regulation of the propagator of a quantum system. This observation leads us to revisit the use of a Fubini–Studyn metric $g^{FS}$ on the space of coherent states (which coincides, up to a multiplicative scalar factor $4$, with $g^{1/2}$, when the latter is extended to the boundary of the pure states) for the purposes of regulation of the propagator of a quantum system.

**Motivated by the Anastopoulos–Savvidou analysis of the term $e^\frac{1}{2}\hat{y}^2$ in the Daubechies–Klauder formula (283) as a holonomy of the Berry connection, we replace it by**

$$\exp\left(i \int dt \langle \Omega_{\phi(t)}, d\nabla^{1/2}(\phi(t))\Omega_{\phi(t)} \rangle_{\mathcal{H}_{\phi(t)}}\right),$$

where $\mathcal{H}_{\phi(t)}$ is the GNS Hilbert space associated with $\phi(t) \in \mathcal{M}(\mathcal{N})$, $\Omega_{\phi(t)}$ is its representing vector, while $d\nabla^{1/2}$ is a $\nabla^{1/2}$ connection 1-form. This is equivalent to a local integral of an infinitesimal entropic projection generated by a quantum Brègman distance $D_{1/2}$ on $\mathcal{M}(\mathcal{N})$. While the necessary mathematical background describing the relationship between entropic projections and geodesic free falls is discussed in Section 2.4.1, let us briefly explain the conceptual perspective behind using it to define the dynamics in quantum theory.

In general, the entropic projections $\Psi_{\mathcal{Q}}^D$ can be used to generate the global temporal evolution of quantum models following the ideas of Jaynes [179, 241, 173, 177], promoted from an absolute to relative entropy by Schrödinger [300, 302, 301, 304, 303, 305, 306] and Hobson [145, 146] (see [118, 120, 341, 50] for the recent account on further developments of these approaches). Given a time dependent set of constraints $\mathcal{Q}(s)$, the map

$$\phi_0 \mapsto \Psi_{\mathcal{Q}(s)}^D(\phi_0) \quad (9)$$

selects a unique trajectory of quantum states, if for each $s$ the set $\mathcal{Q}(s)$ is such that it gives a unique solution to the corresponding minimisation problem (in order to recover the typical formulation of dynamical problems, one may additionally require the map $s \mapsto \Psi_{\mathcal{Q}(s)}^D(\phi_0)$ to be continuous, and $\Psi_{\mathcal{Q}(0)}^D(\phi_0) = \phi_0$).

However, this construction is not the same as local re-updating of the state in time $s$ to the state in time $s + \delta s$ by the new data. While in principle it is nothing wrong with it (after all, the classical action principle $\delta S = 0$ is an inherently nonlocal construction), it is interesting to see whether a local entropic dynamics can be proposed. The equivalence of entropic projections with geodesic projections for the class of Brègman distances $D_{\Phi}$ provides such a possibility. In such case, instead of consideration of subsequent stages of a relative entropy driven evolution that is nonlocally determined by an initial state $\phi_0$, one can just follow the $\nabla^{D_{\Phi}}$-geodesics of the $\nabla^{D_{\Phi}}$-connection (derived from $\Phi$), as a third order

---

11While the definition of $\int \mu \hat{p} \log \frac{\hat{p}}{\hat{q}}$ as well as its conceptualisation as a measure of relative information gain is due to Kullback [219, 218], the use of this object for defining information dynamics can be credited to the above authors.
Taylor expansion, by means of the Eguchi equations, see Section 2.4.1), maintaining the condition of the $(\nabla^{D_P})^+\text{-}\text{convexity}$ and $(\nabla^{D_P})^+\text{-}\text{affinity}$ of the local constraints, as well as their $(g^{D_P}, \nabla^{D_P}, (\nabla^{D_P})^+)\text{-}\text{orthogonality}$ with respect to the local $\nabla^{D_P}$-geodesic trajectory. This way the local user’s inference, based on smooth re minimisation of an information distance (locally $D_{\Psi}$-optimal learning process) becomes equivalent with a free fall along $\nabla^{D_P}$-geodesics. One can call it a local equivalence principle of an “information gravity”. The restriction of an arbitrary $D_{\Psi}$ and $\nabla^{D_P}$ to $D_{1/2}$ and $\nabla^{1/2}$, as expressed by (8), is caused by two reasons: requirement of showing explicit backwards compatibility with the Daubechies–Klauder path integrals, and also the structural restrictions of the GNS bundle.\textsuperscript{12} In order to use other $\nabla^{D_P}$ connections, we would have to systematically apply noncommutative Orlicz spaces, which is beyond the scope of this paper.

In addition, we replace an affine function $h(z(t))$ in the Daubechies–Klauder formula (282), which is corresponding to a Killing hamiltonian vector field and is generated by a coherent state expectation $\langle \hat{a} \rangle$, understood as an element of the local space of quantitative effects, such as the self-adjoint observables $\hat{a}$. While one can chose $t \in [r_0, r_1]$ and $s \in [r_1, r_2]$, $r_0, r_1, r_2 \in \mathbb{R}$, there is no obligation to do so. In general, $u_t^{B,h}$ represents a causal evolution governed by the principle of a local conservation of absolute energy (understood as an element of the local space of quantitative effects, such as the self-adjoint observables in quantum mechanics), while $\mathcal{P}_Q^{D}(s)$ represents an inferential evolution governed by the principle of a global growth of relative entropy (understood as a function on the global space of states). It was first observed by Kępiński\textsuperscript{192, 193} that each of those dynamical processes carries its own notion of time.

Our work grew out from consideration of this duality, and a priori independence of two associated notions of time, as the fundamental principle of physical dynamics. In the context of the present paper, as we discuss it below, we postulate that the ‘energetic’ time of causality and the ‘entropic’ time of inference are equal, but only infinitesimally.\textsuperscript{13} This forms the first principle of local information dynamics. More precisely, we consider the local causal dynamics, governed by $d_{\nabla^{D_P}}$, and the local inferential dynamics, governed by $d_{\nabla^{\nabla^{D_P}}}$, as two independent fundamental dynamical processes that should be treated on the equal footing as components generating jointly an infinitesimal temporal evolution in a single time. In other words, we postulate that the complete description of the local dynamics should be governed by a differential 1-form

$$\mathcal{F}_{D_{\Psi},h_{\Psi}} := d_{\nabla^{D_{\Psi}}} + d_{\nabla^{\nabla^{D_{\Psi}}}}.$$  

However, the existing constructions of a quantum information manifold use different tangent-coin tangent space structure than the quantum Poisson spaces, so, as a result, the addition operation in (11) is precisely as meaningful, as is adding the element of the noncommutative Orlicz space to the element of a Banach Lie subalgebra $\mathcal{B}$ of $\mathcal{N}_{\text{sa}}$ (or of $\mathcal{N}$, if one wants to use some nonstandard

\textsuperscript{12}Using Hasegawa\textsuperscript{137} representation of a tangent space in terms of functions of density operator, we could generalise the use of the GNS bundle at least to the case of $\nabla^n$ connections derived from $\mathcal{D}_\psi$. However, this would be restricted to the finite dimensional case. Moreover, we are interested here more in the search of an appropriate analytic setting for the general theory than in the explicit calculations of special finite dimensional cases.

\textsuperscript{13}Due to incoherence between the standard use of the word ‘local’ in physics and in mathematics, it is hard to propose any universally optimal terminology for distinguishing between different regimes. In this paper we use the terms: global to refer to objects acting on all space $\mathcal{M}$; local and (equivalently) infinitesimal to refer to objects acting at $\phi \in \mathcal{M}$; nonlocal to refer to objects acting in some neighbourhood of $\phi \in \mathcal{M}$ (maybe quasi-local would be a better term). Within our setting, the local regime corresponds to a single user system, defined by the states-and-effects kinematics equipped with the causal-inferential dynamics, global regime corresponds to a multi-user framework, while nonlocality corresponds to the issues of construction of effective multi-user kinematics and dynamics, based on the choice of specific criteria of synchronisation between individual user’s systems, at the expense of some individual properties being no longer maintained at the effective level. See Sections 1.4 and 1.5 for more discussion.

\textsuperscript{14}The notation $d_{\mathcal{H}(\cdot))_{\Psi}}$ would be completely precise, and symmetric with the notation $d_{\nabla^{\nabla^{D_{\Psi}}}}$, but also quite expensive visually.
Hence, if the resulting geometrisation of a contribution to construct the evolution 
\[ \frac{\partial}{\partial t} P_{i} = \sum_{\ell \in I} P_{\ell} \frac{\partial}{\partial t} P_{i}(t) \] 

is determined by the nonhamiltonian change of probabilities \( \{ p_{1}(t), \ldots, p_{n}(t), \ldots \} \) that determine \( \rho(t) \) by means of \( \rho(t) = \sum_{\ell \in I} P_{\ell} p_{\ell}(t) \), given \( \sum_{\ell \in I} P_{\ell} = \mathbb{I} \), \( P_{i} P_{j} = \delta_{ij} P_{i} = \delta_{ij} P_{j} \), and \( P_{i} \in \text{Proj}(\mathfrak{B}(\mathcal{H})) \) \forall i \in I. Grandy, following Jaynes [179, 172, 175], proposes to use maximum absolute relative entropy to construct the evolution \( p(t) \). As compared to Jaynes’ approach, we propose to replace the use of absolute entropy on probability densities by the use of relative quantum entropies on quantum states. The resulting geometrisation of a contribution \( \frac{\partial}{\partial t} \rho(t) \) by means of a connection 1-form \( d_{\nabla^{1/2}}(\phi(t)) \) can be provided by a choice of a frame (ordered list of vector fields) \( \xi(t) := (\xi_{1}(t), \ldots, \xi_{n}(t), \ldots) \in \mathcal{H}_{\rho(t)} \), such that \( |\xi_{i}(t)|^{2} = p_{i}(t) \forall i \in I \), and evaluation 
\[ (d_{\nabla^{1/2}})^{j}_{k}(\rho(t)) = \sum_{k} (\Gamma^{1/2})^{j}_{k} \xi_{i}(t) \rho_{i}(t) \] 

Contracting the missing indices with \( \xi^{i}(t) \), we derive the explicit representation of (8) as 
\[ \exp \left( i \int dt \xi_{j}(t) \sum_{k} (\Gamma^{1/2})^{j}_{k} \xi_{i}(t) \rho_{i}(t) \right) . \] 
Hence, if one implements the principle (10) as a formal equation 
\[ \hat{\rho}(t) = -i \left[ \mathcal{F}_{\xi_{j},\nabla^{1/2}}(\rho(t)), \rho(t) \right] , \]
then the latter can be represented in the above situation as

$$i\frac{d}{dt}\rho = [\mathbf{d}h(\rho(t)), \rho(t)] - \sum_{k,i}(\Gamma_{\nabla^{1/2}})^j_{ki}(\xi(t))P^k_i - J_{\rho(t)} P^i J_{\rho(t)}, \quad (17)$$

where the modular conjugations $J_{\rho(t)}$ arise from a commutator of $\mathbf{d}_{\nabla^{1/2}}$ with $\rho(t)$.

Alternatively, taking into account our earlier observation that the standard transition unitary $V_{\omega,\phi} = J_{\omega} J_{\phi,\omega}$ is exactly a parallel transport of $\nabla^{1/2}$, we can begin from the $\nabla^{1/2}$-parallel transport equation of a vector $v^a$ along the trajectory $\rho(t)$,

$$\frac{d}{dt}v^a(t) = -\sum_{b,c}(\Gamma_{\nabla^{1/2}})^a_{bc}(\rho(t))v^b(t)\left(\frac{d}{dt}\rho(t)\right)^c. \quad (18)$$

Substituting $v = \dot{\rho}(t)$, and integrating out, we get

$$i\frac{d}{dt}\rho(t) = -\int_{-\infty}^{t} dt \sum_{b,c}(\Gamma_{\nabla^{1/2}})^a_{bc}(\rho(t))\left(\frac{d}{dt}\rho(t)\right)^b\left(\frac{d}{dt}\rho(t)\right)^c. \quad (19)$$

This equation, describes the equation of motion of the free fall along the $\nabla^{1/2}$-geodesic trajectory $\rho(t)$, when represented in the GNS Hilbert space bundle by means of $\mathcal{H}_{\rho(t)} \cong \mathfrak{S}_2(\mathcal{H})$.

An infinitesimal transformation $\rho \mapsto \rho + \delta \rho$ can be decomposed as [137]

$$\delta \rho := \tilde{\delta} \rho + [\rho, W] = \sum_{i=1}^{n}\left(\frac{\partial \rho(\theta)}{\partial \theta^i} + [\rho, W_i]\right) \mathbf{d}\theta^i, \quad (20)$$

where $\tilde{\delta} \rho = \sum_{i=1}^{n}\frac{\partial \rho(\theta)}{\partial \theta^i} \mathbf{d}\theta^i$ is defined by $[\tilde{\delta} \rho, \rho] = 0$, and $W = \sum_{i=1}^{n} W_i \mathbf{d}\theta^i$ is an antiself-adjoint operator (hence, $k^+_i = k_i := iW_i$). The mappings $\partial, \tilde{\partial}$ and $[\cdot, W]$ are derivations on $\mathfrak{B}(\mathcal{H})$. This determines a decomposition of tangent space at $\rho$ into the direct product of the corresponding subspaces. An explicit representation of the tangent space in terms of $\mathfrak{S}_2(\mathcal{H})$ space by means of finite dimensional coordinate parametrisation $\mathbb{R}^n \ni \Theta \ni \theta \mapsto \theta(\Theta) \in \mathfrak{S}_2(\mathcal{H})^+$ reads [137]

$$T_{\rho^{1/2}}(u) = \sum_{i=1}^{n} u^i \left(\sqrt{\rho} \frac{\partial \rho}{\partial \theta^i} + 2[\sqrt{\rho}, W_i]\right). \quad (21)$$

As a result of these considerations, if we interpret the principle (10) as a statement that the effective local dynamics is generated by the sum of vectors $\dot{\rho}(t)$ arising independently from the hamiltonian flow and the geodesic free fall (19), then we should use the equation

$$i\frac{d}{dt}\rho(t) = [\mathbf{d}h(\rho(t)), \rho(t)] \quad (22)$$

This equation describes the effective local dynamics, including causality and inference effects on the equal footing (thus, parallely processing them). Comparing the nonhamiltonian parts of the equations (17) and (22), we see that the equation (17) can be at best some sort of approximation of (22). We interpret it as an indication of the weakness of the implementation (16), as compared with (22).

The interpretation of (11) an infinitesimal analogue (but not a generator) of the “entropic inference following causal Poisson evolution” global $W^*$-geometric dynamics (3), and the fact that the latter allows to reconstruct CPTP maps as a special case [215, 214], suggests to interpret (22) as a nonlinear geometric analogue of the Lindblad–Gorini–Kossakowski–Sudarshan equation [230, 117].

13
1.4 Curvature measures desynchronisation in the multi-user inference

In this Section we will consider the problem of the effective nonlocal quantum information dynamics. As opposed to effective local dynamics, which provides the infinitesimal description of causality and inference from the perspective of a single user (thus, allowing for an immediate subjective bayesian interpretation), nonlocality is intended to describe the multi-user (intersubjective) conventions of relating causal and inferential dynamics of individual users. In our opinion the geometric space is an emergent property of the specific intersubjective conventions of information (causal and inferential) dynamics, which is, in turn, relative to a specific choice of (class of) users. In this text we are focused on an analysis of a specific example, rooted in quantum information geometry. More foundational discussion will be postponed to another paper [214].

In principle, given two or more different users, each with his/her own method of providing inferences and evaluating causal evolution, nothing can be said about how their information dynamics is related. If only the inferential aspect of information dynamics is taken into account, then such situation can be understood as incommensurability of inferences provided by different subjective bayesians with their arbitrary choices of respective priors and of methods of updating. In order to relate these different instances of local information dynamics, one needs to introduce some method of translation between the respective evolutions, as well as their initial assumptions. Each such method represents a specific intersubjective convention, which allows to translate between individual instances of information dynamics at the expense of constraining its possible forms to such that are subjectible to a given convention. In particular, for inferential part of the information dynamics, there should be a way of identification of a given state of information as ‘the same’ state for all users under consideration. Note that there is no need for such identification being made globally for all possible users: it is sufficient if one can do it for different sets of users that are under the scope of interest.

The general setting for these considerations can be defined as follows. Given an abstract set \( M \) of users, with a single user represented as a point \( \phi \in M \) equipped with a vector space of local states \( V(\phi) \) and a Banach dual vector space \( V^d(\phi) \) of local effects (one can think of them in terms somewhat similar to [232], but the duality does not have to be carried by Banach space structure, but e.g. by convenient vector space structure).\(^{16}\) In order to model causality and inference, each user can chose locally his/her own ‘causal’ Banach Lie algebra \( B \) acting on \( V^d(\phi) \), as well as its own ‘inferential’ Brègman functional \( \tilde{D}_\Psi \) on \( V(\phi) \), the latter determined by the duality between \( V(\phi) \) and \( V^d(\phi) \) and the choice of a function \( \Psi : V(\phi) \to \mathbb{R} \). Given a set \( U(\phi) \subseteq M \) of users, such that \( \phi \in U(\phi) \), a choice of a function \( \ell_\phi : U(\phi) \to V^d(\phi) \) allows to use the Brègman functional \( \tilde{D}_\Psi : V^d(\phi) \times V(\phi) \to [0, \infty] \) in order to construct the Brègman distance \( D_\Psi(\omega, \psi) := \tilde{D}_\Psi(\ell_\phi(\omega), \ell_\phi(\psi)) \) \(^{23}\)

Thus, the choice of the function \( \ell_\phi \) defines how the local user interprets ‘inferentially’ the subset \( U(\phi) \) of the set \( M \), while the choice of a hamiltonian function \( h(\phi) \) defines how he/she interprets it ‘causally’. The forms \( d_hB(\phi) \) and \( d_{\mathcal{C}}D_\Psi(\phi) \), constructed as elements of \( V^d(\phi) \), are encoding the corresponding infinitesimal dynamics.\(^{17}\) The translation between different users in the set \( Q \subseteq M \) requires, within this model, to specify relationship between \( \ell_\phi \) and \( \ell_\psi \), as well as \( h(\phi) \) and \( h(\psi) \), for all elements \( \phi, \psi \in Q \).

The local state-effect kinematics is completely described using the pair \((V(\phi), V^d(\phi))\) at a given point \( \phi \in M \), while the resulting local causal-inferential dynamics is generated by \((11)\). This leads to a question to what extent, and at what expense, this dynamics can be extended to a larger nonlocal area of \( M \), for example allowing to interconnect the dual pairs of vector spaces of different users by means of the (not necessarily global) sheaf of tangent and cotangent spaces. On the conceptual level, this corresponds to the question how the local (individual) state-and-effect dual pairs of different users

---

\(^{16}\)By the reasons discussed above and below, we postulate that if \( M \) is given by \( M(N) \), then \( V(\phi) \) should be specified as \( L_T(\phi)(N) \). However, in order to distinguish the conceptual and the representational aspects of our approach, we state it in more general terms.

\(^{17}\)On the level of implementation, it is sufficient to model \( V(\phi) \) and \( V^d(\phi) \) as convenient vector spaces in order to guarantee that the infinitesimal calculus is well defined.
φ ∈ ℳ can be mutually related, how their respective causal and inferential local dynamics can be synchronised, and what is the price to pay for it? For example, even if all users (φ, V(φ), V^d(φ)) agree to use the same generating objects for their respective local system of causality (e.g., a Banach Lie algebra ℬ) and local system of inference (e.g., a discrimination function Ψ), their individual choices of functions h_φ(φ) and ℓ_φ may be not extendible to a set ℳ, resulting in sheaves of different effective local dynamics (11). The problem of conditions for integrability of (11) is thus directly related to the issue of nonlocal (multi-user) synchronisation of local systems of causality and inference about local states and effects.

In general, the convention defining emergent multi-user inference can be arbitrarily different from the convention defining the emergent multi-user causality, and they both can differ from any of the local instances of inference and causality that are amalgamated into the emergent structure. As a result, the emergence of a nonlocal spatio-temporal causal-inferential dynamics is be provided at the expense of its departure from the local causal-inferential dynamics. In the context of the structures analysed in this paper, it is represented by the appearance of the system of local entropic priors associated with a specific integral line of a vector field on a model ℳ. (From the closely related point of view, one can notice that the postulate of Section 1.2.2 identifies the local inferential time with local causal time for each individual user separately, but it does not say anything about mutual relationships of those time parameters for different users. In principle, one could also study theories for which the local causal and inferential time of each user would not be identified, yet the multi-user synchronisation of those two temporal structures would be considered. We find this perspective very attractive, but it is beyond the scope of the current paper.)

On the technical level, we observe that the Fubini–Study riemannian metric, used in the regularising term in the Daubechies–Klauder and the Anastopoulos–Savvidou approaches, can be replaced by the second order Taylor expansion g(1/2) of a quantum relative entropy D(1/2). This leads us to postulate to use a quantum entropic prior localised to a neighbourhood of a given state as a general geometric form of the regulariser (see Section 4.7 for a discussion of the notion of an entropic prior in the commutative case). Integration of a local entropic prior along a given trajectory on a state manifold constructs a regularised weight for this trajectory.

On the conceptual level, we interpret the appearance of local entropic prior as a measure of (impossibility of) synchronisation of the causal-inferential dynamics of the subsequent local users at a given spatio-temporal trajectory. More specifically, the choice of a single nonlocal (multi-agent) time trajectory sets up the nonlocal vector field, corresponding to a specific system of synchronisation (= nonlocal/noninertial observation frame) for the local forms ℱ_{DP, h_Ψ}. This choice is arbitrary, but with each such choice, the passage from point to point on the corresponding nonlocal trajectory of a single spatialised time adds an additional term to an effective dynamics along this trajectory. Only some specific conventions of the multi-user inference avoid the path-dependence of the synchronisation of the inference: in the example that we study here they are given by such models (ℳ(ℳ), D_Ψ) for which the scalar curvature κ(∇g^Ψ) is constant over ℳ(ℳ).

One can wonder why this phenomenon of “breaking of symmetry” between causality and inference results in an entropic (hence inferential), as opposed to a hamiltonian (hence causal) contribution. If all users along the trajectory (as well as in the neighbourhood of this trajectory, in order to have a situation that is more canonical than that of a 1-dimensional manifold) agree to have the same choice of ℬ and Ψ, then in principle they should share the same nontrivial inferential and causal geometry, so there is yet no reason for “breaking of the symmetry”. However, the Carathéodory–Jacobi–Lie theorem (which generalises the Darboux theorem) implies that for any symplectic manifold with a hamiltonian function h, the function h is a conserved quantity in an open neighbourhood for any φ for which dh(φ) ≠ 0. An analogous statement is not true in riemannian geometry, as measured by the curvature. The generalisation from symplectic to Poisson geometry and from riemannian to Norden–Sen geometry does not change qualitatively this difference. Thus, the passage from infinitesimal/local (jets) to neighbourhood/nonlocal (germs) is trivial for causality, but not for inference. So, while it is possible to nonlocally synchronise the local causal structure along a trajectory of users (whenever it is modelled by the Poisson geometry), it is impossible to do this with the local inferential structure.
is supplied only by the principle of maximum entropy as a method of reasoning.»

“A useful start on understanding of these phenomena, but still lacking any coherent theoretical basis – which we think algebraic approach.

to construction of germs of algebraic states corresponding to a choice of a specific predictive dynamical theory in the spaces in order to select a specific sheaf of states) was discovered by Bostelmann \[42\] in the Haag–Ojima approach \[129\] a somewhat similar situation (roughly speaking, a necessity of using additional geometric structures on the pre-state equivalently, prior ignorance).

nonlocal integrability of local inferential structure on the local geometry of user’s prior knowledge (or, into a single statement: zero-point energy’s point-dependence is a manifestation of a dependence of in a given hypothesis space» \[289\]. Our formulation recombines the above insights, integrating them entropic priors \[288\] interpreting them as the “statistical representation of the vacuum of information

analogue of Einstein’s principle of equivalence of gravitational (inferential) and inertial (causal) mass.

would cancel the contribution arising from the local entropic priors can be then considered to be an \[\mathcal{F}_{\mathcal{D}_\Psi, h_H} = 0\] (whenever valid) can be understood as a causal-inferential analogue of Einstein’s version of Newton’s first law of motion \(\text{(for a single user, from his/her own perspective)}\), the local priors are somewhat similar to the second law of thermodynamics or to the universality of the gravitation: the globalisation of inferences is provided at the expense of inevitability of making those inferences dependent on additional arbitrary assumptions, that are in principle different for each user, and are nonobservable in the infinitesimal causal-inferential reference frame. The shadow of dependence of the multi-user inferences, as well as of the effective nonlocal causal-inferential dynamics, on arbitrary additional assumptions \(\text{(attributed to other users by the user residing at the end point of the integrated trajectory)}\) is a price paid for a requirement of global spatialisation of the inferential dynamics. The lack of the similar effect in the case of causal dynamics is in essence a result of a local linearity of the Banach Lie–Poisson spaces. If other mathematical structure would be chosen to model causality, the similar dialectics may occur. For example, one could model causal dynamics by means of extremum of quantum relative free energies, defined as the Legendre–Fenchel conjugates of quantum information distances. The nonlocal trivialisation of the causal structure by means of the CJL theorem would not be applicable in such case. As a result, the dual, local relative free energy priors, should be also included, as an additional regularising term, into integration giving rise to an effective dynamics. In general, we propose to consider the priors on the model \(\mathcal{M}\) as an information theoretic analogue of the notion of mass, so the local prior at the neighbourhood \(U(\phi)\) of \(\phi \in \mathcal{M}\) can be interpreted as an information theoretic analogue of the mass of the user \(\phi\) distributed over the set \(U(\phi)\) of users. The special case in which the integration against the local relative free energy priors would cancel the contribution arising from the local entropic priors can be then considered to be an analogue of Einstein’s principle of equivalence of gravitational (inferential) and inertial (causal) mass.

As observed in \[235, 3, 365\], if the riemannian geometries of the phase space used for the Wiener measure regularisation have nonconstant scalar curvature, then the weighting of the phase space paths is nonuniform, corresponding to the phase space point dependency of the zero-point energy. On the other hand, in a completely different context, Jaynes has argued \[166, 171, 176\] that the zero-point energy should be interpreted not as an ontic feature of the system, but as observer’s measure of uncertainty regarding his/her own prediction of the value of energy, as based on his/her own prior information. Quite independently from these considerations, Rodríguez has developed the theory of entropic priors \[288\] interpreting them as the “statistical representation of the vacuum of information in a given hypothesis space” \[289\]. Our formulation recombines the above insights, integrating them into a single statement: zero-point energy’s point-dependence is a manifestation of a dependence of nonlocal integrability of local inferential structure on the local geometry of user’s prior knowledge (or, equivalently, prior ignorance).\[10\]

\[18\]While a detailed discussion of this phenomenon is beyond the scope of the current paper, we want to note that a somewhat similar situation (roughly speaking, a necessity of using additional geometric structures on the pre-state spaces in order to select a specific sheaf of states) was discovered by Bostelmann \[42\] in the Haag–Ojima approach \[129\] to construction of germs of algebraic states corresponding to a choice of a specific predictive dynamical theory in the algebraic approach.

\[19\]This gives also some justice to an otherwise quite cryptic remark of Jaynes on the book \[277\] on functional integration: «A useful start on understanding of these phenomena, but still lacking any coherent theoretical basis – which we think is supplied only by the principle of maximum entropy as a method of reasoning.» \[178\].

16
However, while our proposal is well founded on the geometric side, and has also an interesting information theoretic interpretation, it has to be regarded as heuristic from the perspective of stochastic process based foundations for path integration. More specifically, the Daubechies–Klauder formulation relies on the interpretation of $\int dt \rho \dot{q} = \int dt \rho$ as the Stratonovich integral (so $\rho \dot{q}$ is considered as a Stratonovich differential $d_\rho \dot{q}$), and on the interpretation of (roughly) $\int \mathcal{D}p \mathcal{D}q e^{-\frac{1}{2} \int dt (\rho^2 + \dot{q}^2)}$ as the pinned Wiener measure (see [35] for a systematic mathematical treatment of these objects in terms of the Berezin–Toeplitz operators). The generalisation to a wide class of connections $\nabla^{D_\rho}$ and local entropic priors (even if kept at the second order riemannian level of $g^D$) asks for a systematic development of a technique of stochastic integration of random walks $X$ on $\mathbb{R}^n$ associated with the Brownian motions on smooth manifolds $\mathcal{M}$, $\dim \mathcal{M} = n$, that could systematically address the functional integration of the above geometric structures beyond the level of heuristic treatment that is standard for physicists. In particular, following [149, 190], let us consider the system of stochastic differential equations

$$d_SX = e d_S B,$$

$$d_S e = H e d_S X,$$

where $d_S$ are Stratonovich differentials, $B$ is an euclidean brownian motion on $\mathbb{R}^n$, frame $e$ is a map from $\mathbb{R}^n$ to the tangent space of $\mathcal{M}$, and $H$ is a horizontal lift of a tangent space at $X$ to the tangent space at $e$, dependent on the choice of an affine connection $\nabla$ on $\mathcal{M}$. If this connection is not Levi-Civita, then the process $X$ will be not markovian. Furthermore, a suitable riemannian metric reproducing the Laplace–Beltrami operator can be uniquely constructed by an appropriate choice of an elliptic diffusion. Hence, the exact mathematical foundation for our generalisation of the Daubechies–Klauder formula is possible at least for the second order Taylor expansion of the entropic prior and for different connections $\nabla^{D_\rho}$. While we consider the task of a systematic treatment of this topic to be of high importance, it will be left beyond the scope of this paper.

The issue of renormalisation cannot be omitted in any foundational discussion of local quantum dynamics. Section 5 is dedicated to the study how the tools of quantum information geometry can be used in order to deal with the tasks of renormalisation. In Sections 5.1 and 5.2 we briefly review the Jaynes–Mitchell source theory [241, 173, 177, 118, 120] and its geometric generalisation by Favretti [100], respectively. This approach provides a geometric implementation of the idea of renormalisation of dynamics by reduction of dimensionality of the model by fixing the control parameter, which is specified as a constraint on the space of information states (as opposed to the space of functions or operators). We observe that the Jaynes–Mitchell–Favretti approach is canonically related to the use of Brègman distances, and that it can be used to provide a local description of entropic information dynamics and multiparameter nonlinear quantum control problems on an arbitrary quantum manifold. The key insight of this approach can be summarised as: renormalisation of the action of control parameters (sources) leads to departure of the geometry of a model $\mathcal{M}$ from a dually flat one. Hence, the appearance of nonzero curvature is an indicator of a nontrivial constraints for information dynamics. Moreover, the nonconstancy of this curvature indicated local dependence of these constraints. From the perspective of our approach to the Daubechies–Klauder path integrals, we postulate that the renormalised description of dynamics should use renormalised riemannian metric $g$ instead of $g^D$ in the regulariser. This corresponds to replacement of a “vacuum of information” by the “vacuum of information storing the shadow of the knowledge about the sources that were renormalised out”.

We also introduce another type of information geometric renormalisation of inferential dynamics of quantum states, which describes situations where none of specific control (covariate) parameter is fixed, but the quantum model is subjected to the action of completely positive maps. This procedure is based on the use of $D_\rho$ distances as well as associated contraction coefficients, introduced by Ruskai et al [72, 64, 203, 227]. For an alternative (and essentially more developed) approach to renormalisation based on $D_1$ on $\mathcal{N}^*_+$, see [30, 31, 32] (c.f. [79] for a pedagogical introduction).
1.5 Locally quantum multi-user information relativity

The discussion in this paper is aimed at the construction of the framework of the multi-user (intersubjective) information relativity with emergent spaces. While most of discussion is kept in the framework build upon the W*-algebras, it is more a useful testing ground (and a verifying constraint for backwards compatibility), then a desired property of the framework. In other words, our intention is to get rid of the *Postulate 1 of Section 1.1* by a suitable reformulation of the *Postulate 5 and 6*. We propose to consider the following tentative structure:

1) Consider arbitrary set \( \mathcal{M} \) of users.

2) Each user \( \phi \in \mathcal{M} \) is equipped with his/her own vector space \( V(\phi) \) containing his/her description of ‘states’ (‘configurations’, ‘preparations’, ‘inputs’) and a dual vector space \( V^d(\phi) \), containing his/her description of ‘effects’ (‘registrations’, ‘results’, ‘outputs’).

3) User’s notion of inference (respectively, causality) is modelled by a choice of set of of endomorphisms of \( V(\phi) \) (respectively, \( V^d(\phi) \)).

4) In particular, inferences on \( V(\phi) \) can be provided by means of the Brègman functional \( \bar{D}_{\Psi,\phi} : V(\phi) \times V(\phi) \to [0, \infty] \), while the causality on \( V^d(\phi) \) can be provided either by the Legendre–Fenchel conjugate of \( \bar{D}_{\Psi,\phi} \), or by a representation of some Lie algebra.

5) More specifically, if one wants to do statistical inference, it is necessary to make clear how the behaviour of finite data sets is associated with the specific idealisations used in the theoretic framework, as represented by the ‘ideal’ theoretical states and effects. In order to assert such relation, it is necessary to admit some statistical tools that are representing the control over a ‘convergence to an ideal form of a data set’, for any given nonideal form of a real data set. Large number estimation and asymptotic estimation are two typical tools (on the geometric level, they correspond, respectively to relative entropy maximisation, and the local linearity). If a user introduces a discrimination function (information potential, absolute entropy) \( \Psi_{\phi} : V(\phi) \to ]-\infty, +\infty] \), then he/she is able to quantify the rates of convergence of sequences of data. The key property of the Brègman functional is that it allows for a generalised pythagorean theorem \((144)\), which is a nonlinear generalisation of the fundamental property of euclidean and Hilbert spaces. Yet, it is doing it without necessity of assuming that \( V(\phi) \) is normed, or even metrisable. As a result, user’s local inferences on \( V(\phi) \) based on entropic projections \( \mathbb{P}^{D_{\Psi,\phi}} \) allow to decompose the information distance to an ‘ideal inference’ \((\bar{D}_{\Psi,\phi}(x, y))\) into a sum of a distance to an effective solution (satisfying given constraints and minimising the distance) and an uncertainty within the constrained space. (By the Legendre–Fenchel duality, completely parallel considerations are applicable to causality on \( V^d(\phi) \) determined by the relative free energy \( D_{\Psi,\phi} : V^d(\phi) \times V^d(\phi) \to [0, \infty] \).)

6) The geometric structures on the set \( \mathcal{M} \) are introduced as quantitative means of relating (synchronising) inferences and causality of different users.

7) Each user \( \phi \) provides his/her own mappings from \( \mathcal{M} \) into \( V(\phi) \), given by bijective embeddings \( \ell_{\phi} : U(\phi) \to V(\phi) \), where \( U(\phi) \subseteq \mathcal{M} \) is the subset of users in \( \mathcal{M} \) that a user \( \phi \) considers as representable in terms of his/her ‘configuration’ space \( V(\phi) \).

8) Using the embeddings \( \ell_{\phi} \), each user can relate his/her individual inferences on \( V(\phi) \) with other users using (a part of) the same set \( U \). In particular, the relative Brègman entropy \( D_{\Psi} \) on \( \mathcal{M} \) is induced by

\[
\bar{D}_{\Psi,\phi}(\ell_{\phi}(\omega_1), \ell_{\phi}(\omega_2)) = D_{\Psi,U(\phi)\cap U(\psi)}(\omega_1, \omega_2) = \bar{D}_{\Psi,\psi}(\ell_{\psi}(\omega_1), \ell_{\psi}(\omega_2)) \quad \forall \omega_1, \omega_2 \in U(\phi) \cap U(\psi).
\]

This provides the means to relate the *large number* inferential dynamics of different users (such as in Sanov’s theorem).
8) The local smooth manifold structure induced by $D_\Psi$ on $\mathcal{M}$ provides the means to relate asymptotic inferential dynamics of different users. In particular, the equivalence of local geodesic projection and local $D_\Psi$ projections can be understood as a method of locally linear synchronisation of inferences of different users. In such case the curvature of the manifold $\mathcal{M}$ measures impossibility of ideal synchronisation of inferences between different users. The relationships with the notions of causality, effective dynamics, and renormalisation were discussed in the previous Section. They are dependent only on the notion of Brègman distance on an arbitrary smooth manifold $\mathcal{M}$, hence they hold in general, without assuming that $\mathcal{M}$ is a subset of $\mathcal{N}_\Psi^\ast$ for some $W^*$-algebra $\mathcal{N}$.

9) The reconstruction of the special case, when $\mathcal{M}$ is equal to the set $\mathcal{M}(\mathcal{N})$ of states over a globally defined $W^*$-algebra $\mathcal{N}$ is an open problem. Our conjecture is that quantum mechanics can be characterised as a set $\mathcal{M}$ equipped with an induced structure of the riemannian manifold $(\mathcal{M}, g^{D_\Psi})$ and a Poisson manifold such that the set of extremal points of the convex hull of $\mathcal{M}$ admits an induced metric and induced symplectic structure that determine a Kähler manifold satisfying the standard properties of the quantum mechanical Kähler manifolds.

In principle, the above scheme is applicable to a wide class of postquantum information theoretical settings, such as general probabilistic theories. In what follows, having in mind the possible applications in nonequilibrium quantum statistical mechanics, we will focus on its implementation in the context of $W^*$-algebras and the associated functional analytic spaces.

While (313) considers only the case of local $\nabla^{1/2}/D_{1/2}$-projections, [139, 211, 215] consider only the case of global $D_\Psi$-projections. Yet, we think that the natural geometric objects for construction of local and nonlocal quantum kinematics and dynamics are arbitrary Banach Lie algebras (to describe causality) and arbitrary quantum Brègman distances (to describe inference), connected together via dual pairs of noncommutative Orlicz spaces. More specifically, following a discussion in Section 1.2.2 we think that the problems considered in this paper should be readdressed in a more general foundational framework, based on the following principles:

1) The use of GNS Hilbert bundle should be replaced by a suitable bundle of noncommutative Orlicz spaces $L_{\Psi}(\mathcal{N})$ playing the role of tangent spaces $T_\phi \mathcal{M}(\mathcal{N})$, understood as the spaces of local ‘configurations’ (e.g. $\phi(\theta) \mapsto \theta \mapsto \left(\frac{d\theta}{d\phi}\right)$), with their Banach duals $L_{\Psi}(\mathcal{N})^*$ playing the role of cotangent spaces $T^*_\phi \mathcal{M}(\mathcal{N})$, understood as the spaces of local ‘effects’ ($f(\phi) \mapsto df \mapsto (df_\phi)$). Somewhat similar ideas were considered earlier in [341, 233], but only in a global context, restricted to a single ‘tangent’ and ‘cotangent’ space.

2) There should be provided a canonical construction of a quantum Brègman distance $D_\Psi$ associated with a Banach dual pair $(L_{\Psi}(\mathcal{N}), L_{\Psi}(\mathcal{N})^*)$, a function $\Psi : L_{\Psi}(\mathcal{N}) \rightarrow \mathbb{R}$, and a family of embeddings $t_\phi : \mathcal{N}_\Psi^\ast \rightarrow L_{\Psi}(\mathcal{N})$, such that the second order Gâteaux derivative of $D_\Psi$ determines a map

$$g_{D_\Psi} : L_{\Psi}(\mathcal{N}) \times L_{\Psi}(\mathcal{N})^* \rightarrow [0, \infty],$$

while the third order Gâteaux derivatives determine the connections $\nabla^{D_\Psi}$ and $(\nabla^{D_\Psi})^\dagger$, with the respective parallel transports equal to the isometric transition operators

$$t^{\nabla^{D_\Psi}} : T_\phi \mathcal{M}(\mathcal{N}) \rightarrow T_\omega \mathcal{M}(\mathcal{N}),$$

$$t^{(\nabla^{D_\Psi})^\dagger} : T^*_\phi \mathcal{M}(\mathcal{N}) \rightarrow T^*_\omega \mathcal{M}(\mathcal{N}),$$

and satisfying the generalised Norden–Sen duality

$$g_{D_\Psi}(t^{\nabla^{D_\Psi}}(x), t^{(\nabla^{D_\Psi})^\dagger}(y)) = g_{D_\Psi}(x, y).$$

This is intended to implement the principle discussed in Section 2.4.3: the local structure of an information manifold should implement the local equivalence of an entropic projection (user’s inference) and a geodesic free fall (an absence of geometric ‘gravity’).
3) Lie algebras $\mathfrak{g}$ and Banach Lie algebras $\mathcal{B}$ should be represented on $L_{T(\phi)}(\mathcal{N})^*$, the latter giving rise to a Banach Lie–Poisson manifold structure on $\mathcal{M}(\mathcal{N})$ determined by the action of $\mathcal{B}$ on $L_{T(\phi)}(\mathcal{N})$.

4) As a result, both $d_{\nabla \phi} d_{\mathcal{B}}$ and $dh_{\mathcal{B}}(\phi)$ become the elements of the same operator space $L_{T(\phi)}(\mathcal{N})^*$, so the local effective dynamics can be formulated in terms of a 1-form $\mathcal{F} = dh_{\mathcal{B}} + d_{\nabla \phi}$, treating local causality and local inference on an equal footing. Note that, in face of the discussion in Sections 1.2.1, 1.2.2, and 2.4.3, the condition $\mathcal{F} = 0$ can be understood as an information-theoretic analogue of Einstein’s version of Newton’s first law of motion: a rest in a local causal-inference frame (provided by user’s choice of generators $\mathcal{B}$ for causal dynamics in a cotangent space of effects, and a discrimination function $\Psi$ for inferential dynamics in a tangent space of states).

5) The local tangent BLP hamiltonian vector field, generating a local W*-dynamical system associated with a local fiber of a GNS Hilbert bundle, should be represented in terms of $L_{T_\gamma}$-liouvillean, acting on the $L_{T(\phi)}(\gamma)$ tangent space. The incorporation of the contribution of the local free fall along $\nabla^{d_\phi}$-connection geodesics should be provided by the perturbation of this $L_{T_\gamma}$-liouvillean, defined in an analogy with the Jakšić–Pillet $L_{1/\gamma}$-liouvillean [165].

6) The local entropic prior should be constructed using $D$ and $g^D$ representing the effective geometry of a model $\mathcal{M}(\mathcal{N})$, after the renormalisation of all contributions from control sources. One can interpret the local entropic prior at a point $\phi \in \mathcal{M}$ as an information theoretic analogue of the (inferential) mass of the user at $\phi$. This interpretation gives a particularly neat meaning to the observation [235, 3], discussed in Section 1.2, that the regularising term in the Daubechies–Klauder formula leads to a point-dependence of a zero-point energy iff the curvature of the Fubini–Study metric is nonconstant. From our point of view, it means: the curvature $\kappa^{D_\phi}$ of a quantum model is a measure of desynchronisation of the ideal multi-user inference (as given locally by $\nabla^{d_\phi}$-geodesics, or, equivalently, $d_{\nabla \phi}$), reflected in the influence of a local mass on the local zero-point energy. The case of information model with a constant curvature is an inferential analogue of the Carathéodory–Jacobi–Lie theorem for symplectic manifold, allowing for a global trivial synchronisation of local causality systems.

7) Given these constructions, the dynamical Ansatz (313) should be generalised by means of the replacement of the GNS Hilbert bundle by a corresponding dual bundle of noncommutative Orlicz spaces.

8) In principle, every quantum Brègman functional $\tilde{D}_\Psi$ on $L_{T(\phi)}(\mathcal{N})$ determines the Legendre–Fenchel conjugate functional $D_{\Psi}^{L}$ on $L_{T(\phi)}(\mathcal{N})$, which can be naturally interpreted as a relative free energy. If one would replace the use of the (nonlocally trivially synchronisable) 1-form $dh_{\mathcal{B}}$ by the form $d_{\nabla \phi} L$, then it would be necessary to introduce a corresponding local entropic prior (causal mass), measuring the influence of desynchronisation of local systems of causality, along the spatial trajectory on $\mathcal{M}$, on the effective quantitative nonlocal evolution. The postulate of the local cancellation of effects of those two (inferential and causal) priors, when integrated together, would be an information theoretic analogue of the postulate of equality of gravitational and inertial mass.

9) In the JMF source theoretic approach the local departure of riemannian metric from the hessian geometry is described by the equation (382). Applying the change of geometry $g^{D_{\phi}} \rightarrow \tilde{g}$ to a definition of a prior $\exp \left( -\frac{\hbar^2}{2} \int dt \sum_{i,j} g_{\alpha\beta}(\phi) \dot{\phi}^i \dot{\phi}^j \right) \sqrt{\det(\tilde{g}(\phi))}$, we can see that the change of the scalar curvature $\kappa(\phi)$ of the model is reflected in the redefinition of the local prior (information mass) $P$. This leads to a more general problem. Given any neighbourhood $U \subseteq \mathcal{M}$ of a user $\phi \in \mathcal{M}$, one can ask how to determine the departure of a prior $P$ on $U$ (from the originally postulated one) that is caused by the changes of curvature $\kappa$ of a model $\mathcal{M}$ associated with a given system of inference, when the transformation of geometry of a model $\mathcal{M}$ (e.g., due to the Jaynes–Mitchell renormalisation) is considered. The analogy with general relativity that we
were pursuing in this paper, as well as an observation [365] that the uniform weighting of the trajectories requires constant scalar curvature, leads us to conjecture that

\[
\delta \int_U P = \delta \int_U \kappa.
\]

We hope that this mathematical framework will allow for a unified treatment of the foundations of nonequilibrium quantum statistical mechanics, as discussed from different perspectives in [120], [341], and [165] (see also [50]). More generally, we consider it to be a testing ground for a construction of a predictive dynamical theory that would unify several concepts of general relativity with quantum information theory into a single framework of multi-agent (post)quantum information relativity. Maybe this sounds a bit like a fountain of conjectures and high hopes, but we believe that the science fiction of today is just an advanced propagator of a scientific research of tomorrow.

## 2 Quantum geometry & global dynamics

Sections 2.1, 2.2, 2.4.1, 2.4.2 do not contain new results or constructions, except of the definition of the quantum Poisson system.

### 2.1 Quantum Banach–Poisson spaces

#### 2.1.1 Banach–Lie–Poisson spaces

Let \( \mathbb{K} \in \{ \mathbb{R}, \mathbb{C} \} \). A vector space \( X \) over \( \mathbb{K} \) is called a **Lie algebra** iff it is equipped with a function \([\cdot, \cdot]: X \times X \to X\) such that for all \( f_1, f_2, f_3 \in X \) and for all \( \lambda \in \mathbb{K} \)

1. \( [f_1, f_2] = -[f_2, f_1] \) (antisymmetry),
2. \( [f_1, f_2 + \lambda f_3] = [f_1, f_2] + \lambda[f_1, f_3] \) (linearity),
3. \( [f_1, [f_2, f_3]] + [f_3, [f_1, f_2]] + [f_2, [f_3, f_1]] = 0 \) (Jacobi identity).

The function \([\cdot, \cdot]\) is called the **Lie bracket**. If \((X, [\cdot, \cdot])\) satisfies also the Leibniz’s rule

4. \( f_1, f_2 f_3) = f_1 f_2 f_3 + f_2 f_1 f_3 \) \( \forall f_1, f_2, f_3 \in X \),

then \([\cdot, \cdot]\) is called the **Lie–Poisson bracket** [229], while \((X, [\cdot, \cdot])\) is called a **Lie–Poisson algebra**. If \( G \) is a Lie group, then a Lie algebra of its generators will be denoted \( \text{Lie}(G) \). A vector space \( X \) over \( \mathbb{K} \) is called a **Banach Lie algebra** iff it is a Banach space with a norm \( \|\cdot\| \), a Lie algebra, and its Lie bracket \([\cdot, \cdot]: X \times X \to X\) is bilinear and continuous in the topology of \( \|\cdot\| \). If \( g \) is a Banach Lie algebra, then the adjoint map \( \text{ad}_g: g \ni y \mapsto [x, y] \in g \) and coadjoint map \( \text{ad}^*_g: g^* \to g^* \),

\[
\| y, \text{ad}^*_g(z) \|_{g \times g^*} := \| \text{ad}_g(y), z \|_{g \times g^*} \quad \forall z \in g^*;
\]

are norm continuous for each \( x \in g \).

Let \( M \) be a real Banach smooth manifold, and \( C_F^\infty(M; \mathbb{R}) \) denotes the space of all infinitely Fréchet differentiable \( \mathbb{R} \)-valued functions on \( M \). Then a real **Poisson structure** on \( M \) is defined as a function \([\cdot, \cdot]: C_F^\infty(M; \mathbb{R}) \times C_F^\infty(M; \mathbb{R}) \to C_F^\infty(M; \mathbb{R}) \) such that \((C_F^\infty(M; \mathbb{R}), [\cdot, \cdot])\) is a Lie algebra [229]. If \( M \) above is **finite dimensional**, then \((M, [\cdot, \cdot])\) is called a real **Poisson manifold** [228, 367, 354, 368]. If \( M \) is a real Banach smooth manifold, then the cotangent space at \( x \) can be defined by \( T_x^* M := (T_x M)^* \), and each element of \( T_x^* M \) has a form

\[
d f(x) \equiv d_x f : T_x M \ni v \mapsto d_x f(v) := v(f) \in \mathbb{R}
\]

for some \( f \in C_F^\infty(M; \mathbb{R}) \). Let \( T^*\mathbb{R} M := \bigcup_{x \in M} T_x^* M \), where \( T_x^* M \) is a **Poisson vector field** in \( T_x M \) determined by \( \mathbb{R} \)-valued functions on \( M \) by

\[
\mathbb{X}_k(f) := \bigcup_{x \in M} \left\{ x \mapsto [\mathbb{X}_k(x), d f(x)]_{T_x M \times T_x M} \right\} = \{ f, k \} \forall f \in C_F^\infty(M; \mathbb{R}).
\]
Moreover, under those conditions the Hamiltonian vector field associated with a smooth function \( f \) is defined by \( \mathbb{X}_f = \frac{\partial f}{\partial q} \mathbb{X} + \frac{\partial f}{\partial p} \frac{\partial}{\partial p} \) for \( (q,p) \in \mathbb{R}^n \times \mathbb{R}^n \). Hence, there exists a smooth section \( \varpi \) of the vector bundle \( \mathbb{T}^\ast \mathbb{T}\mathcal{M} \) such that
\[
\{ f, k \} = \varpi(df, dk). \tag{35}
\]

Let \( \varpi \) be a smooth section, meaning that for each \( x \in M \) there exists a continuous bilinear antisymmetric function \( \varpi_x : T_x^\ast M \times T_x^\ast M \to \mathbb{R} \) such that \( x \mapsto \varpi_x \) is smooth. Let the function \( \mathbb{S} : T^\ast M \to T^\ast \mathbb{T}\mathcal{M} \) be the bundle map covering identity, isometric on fibres, and satisfying
\[
\mathbb{S}_x(df) := \varpi_x(\cdot, df), \tag{36}
\]
which means that
\[
(\varpi_x(df))(dk(x)) = \{ f, k \}(x) \quad \forall f, k \in C^\infty_\mathbb{R}(M; \mathbb{R}). \tag{37}
\]

Then
\[
\mathbb{X}_k := \varpi(\cdot, dk) = \mathbb{S}(dk) = \{ k \} \tag{38}
\]
is a smooth section of \( T^\ast \mathbb{T}\mathcal{M} \), but may not be a vector field on \( M \), because \( T\mathcal{M} \not\subseteq T^\ast \mathbb{T}\mathcal{M} \) in general. In order to solve this problem, Odzijewicz and Ratiu [253] proposed (see also further discussion and results in [254, 27, 28, 255, 351, 287, 252]) to define a real Banach Poisson manifold as a pair \( (M, \{ \cdot, \cdot \}) \) of a real Banach smooth manifold \( M \) and a Poisson structure \( \{ \cdot, \cdot \} \) on it such that the function \( \mathbb{S} : T^\ast M \to T^\ast \mathbb{T}\mathcal{M} \) defined above satisfies \( \mathbb{S}(T^\ast M) \subseteq T\mathcal{M} \).

If \( (M, \{ \cdot, \cdot \}) \) is a real Banach Poisson manifold, then every \( k \in C^\infty_\mathbb{R}(M; \mathbb{R}) \) determines a unique vector field \( \mathbb{X}_k \in \mathbb{T}M \) by (38), and called a Hamiltonian vector field. Such \( k \) is then called the Hamilton function. Every real Poisson manifold is a real Banach Poisson manifold, so this terminology is consistent. Odzijewicz and Ratiu [253] define also a holomorphic Banach Poisson manifold which provides an analogous setting for \( \mathbb{K} = \mathbb{C} \), but we will not use its specific properties here, so we omit its definition. If a Banach space \( X \) over \( \mathbb{K} \) is equipped with a Poisson structure \( \{ \cdot, \cdot \} \) that turns it into a (real or holomorphic) Banach Poisson manifold, then \( X^* \subseteq C^\infty_\mathbb{C}(X; \mathbb{K}) \). Moreover, \( \{ \cdot, \cdot \} \) is linear on \( C^\infty_\mathbb{C}(X; \mathbb{K}) \) if \( \{ X^*, X^* \} \subseteq X^* \).

A Banach–Lie–Poisson space is defined [253] as a pair \( (X, \{ \cdot, \cdot \}) \) such that

1) \( X \) is a Banach space over \( \mathbb{K} \),

2) \( (X, \{ \cdot, \cdot \}) \) is a real (if \( \mathbb{K} = \mathbb{R} \)) or holomorphic (if \( \mathbb{K} = \mathbb{C} \)) Banach Poisson manifold,

3) \( X^* \subseteq C^\infty_\mathbb{C}(X; \mathbb{K}) \) is a Banach Lie algebra with respect to \( \{ \cdot, \cdot \} \).

In such case, the restriction of \( \{ \cdot, \cdot \} \) on \( C^\infty_\mathbb{C}(X; \mathbb{K}) \) to \( X^* \) will be denoted by \( \{ \cdot, \cdot \} \). As proved in [253], the Banach space \( X \) is a BLP space \( (X, \{ \cdot, \cdot \}) \) iff \( X^* \) is a Banach Lie algebra \( \{ X^*, \{ \cdot, \cdot \} \} \) satisfying
\[
\text{ad}^*_X(z) \subseteq X \subseteq X^* \quad \forall x \in X^*, \tag{39}
\]

and in such case \( \{ \cdot, \cdot \} \) is given by
\[
\{ f, k \}(z) = \frac{\partial [\mathbb{D}^\ast f, \mathbb{D}^\ast k]}{\partial z} \quad \forall f, k \in C^\infty_\mathbb{C}(X; \mathbb{K}) \forall z \in X. \tag{40}
\]

Moreover, under those conditions the hamiltonian vector field associated to any \( k \in C^\infty_\mathbb{C}(X; \mathbb{K}) \) reads
\[
\mathbb{X}_k(z) = -\text{ad}^*_X(z) \quad \forall z \in X. \tag{41}
\]

If \( (X, \{ \cdot, \cdot \}) \) is a BLP space, and if \( X \cong \mathbb{T}_xX \forall x \in X \), then \( \mathbb{T}^\ast_xX \cong (\mathbb{T}_xX)^* \cong X^* \), so if \( f \in X^* \), then one can identify \( \mathbb{D}_x f \in \mathbb{T}^\ast_xX \) with \( \mathbb{D}_x f \in X^* \). As a result, for any \( z \in X \) and \( y \in X^* \) the linearity of \( y \) gives \( \mathbb{D}^\ast_y y = y \) and for every \( x \in X \) one has [38, 253]
\[
[y, \text{ad}^*_X(z)]_{X^* \times X^*} = \frac{\partial [\mathbb{D}^\ast y, \mathbb{D}^\ast z]}{\partial z} = \{ y, \mathbb{X}_x(z) \}(z) = -\{ y, \mathbb{X}_x(z) \}(z) \tag{42}
\]
\[
(\mathbb{X}_x(y))(z) = \frac{\partial [\mathbb{D}^\ast y, \mathbb{X}_x(z)]}{\partial z} = -\{ y, \mathbb{X}_x(z) \} = -\{ y, \mathbb{X}_x(z) \} \tag{43}
\]
\[
\{ y, \mathbb{X}_x(z) \} = \mathbb{X}_x(y). \tag{44}
\]
Hence,
\[ X_z(z) = -\text{ad}^*_x(z) \quad \forall z \in X \quad \forall x \in X^*. \]  

(44)

The notion of the BLP space can be viewed as a suitable generalisation of the important properties of \textit{strong} symplectic manifold to infinite dimensional situation which need not admit decomposition into symplectic leaves. If \((M_1, \{\cdot, \cdot\}_1)\) and \((M_2, \{\cdot, \cdot\}_2)\) are BLP spaces, then a smooth function \(w : M_1 \to M_2\) is called a \textbf{Poisson map} if

\[ \{f \circ w, k \circ w\}_1 = \{f, k\}_2 \circ w \quad \forall f, k \in C^\infty(M_2; \mathbb{K}). \]  

(45)

As shown in \cite{237}, the condition iii) above makes (45) equivalent to

\[ X_{k \circ w} = \mathbf{T} w \circ X_{k \circ w} \quad \forall k \in C^\infty(M_2; \mathbb{K}). \]  

(46)

If \((M, \{\cdot, \cdot\})\) is a BLP space and \(h \in C^\infty(M; \mathbb{K})\), then the \textbf{Hamilton equation}

\[ \frac{d}{dt} f(w^h_t(x)) = \{h, f(w^h_t)\}(x) \quad \forall f \in C^\infty(M; \mathbb{K}) \quad \forall t \in \mathbb{R} \quad \forall x \in M \]  

determines a unique \textit{local} map \(w^h : M \to M\), called a \textbf{Hamiltonian flow} of \(h\), which is a Poisson map. The solutions of the equation \(x(t) = w^h_t(x)\) with \(x(0) = x\) need not exist \textit{globally}, that is, for all \(t \in \mathbb{R}\) and all \(x \in M\). If they exist globally, then the Hamiltonian vector field \(\{\cdot, h\}\) is called \textbf{complete}.

### 2.1.2 W*-algebra predual as a BLP space

If \(M\) is a Banach space, and a Banach smooth manifold modelled on itself by means of an identity mapping then for each \(x \in M\) there is a Banach space isomorphism \(\mathbf{T}_x M \cong M\). If \(\mathcal{N}\) is a \(W^*\)-algebra, then the Banach Lie algebra structure of \((\mathcal{N}_*)^* \cong \mathcal{N}\) is given by its commutator \([x, y] := xy - yx\), while \(\text{ad}_x := [x, \cdot] = \Sigma_x - \mathcal{R}_x\) and \(\text{ad}_* x := \Sigma^*_x - \mathcal{R}_x^*\) are defined by weakly-\(*\) continuous maps \(\Sigma_x : \mathcal{N} \ni y \mapsto xy \in \mathcal{N}\), \(\mathcal{R}_x : \mathcal{N} \ni y \mapsto yx \in \mathcal{N}\). The condition \(\text{ad}^*_x(\mathcal{N}_*) \subseteq \mathcal{N}_*\) holds for all \(x \in \mathcal{N}\), so \(\mathcal{N}_*\) is a BLP space that is a holomorphic Banach Poisson manifold (modelled on itself by the atlas consisting of one chart, an identity mapping \(\text{id}_{\mathcal{N}_*}\) with the Poisson structure given by (40),

\[ \phi([D^F_x f, D^F_x k]) = \phi(D^F_x f) \quad \forall f, k \in C^\infty(\mathcal{N}_*; \mathbb{C}) \quad \forall \phi \in \mathcal{N}_*. \]  

(48)

As a result, the Hamiltonian vector field associated to every \(k \in C^\infty(\mathcal{N}_*; \mathbb{C})\) by means of (41) takes a form

\[ X_f(\phi) = -\text{ad}^*_x f(\phi) = \Sigma_x^* f(\phi) - \mathcal{R}_x^* f(\phi) \quad \forall \phi \in \mathcal{N}_*. \]  

(49)

These results, including the BLP space structure of \(\mathcal{N}_*\), were discovered by Bona \cite{36, 37, 38} in the \(\mathcal{N}_* = \mathcal{G}_1(\mathcal{H})\) case, and were generalised to arbitrary \(W^*\)-algebras by Odzijewicz and Ratiu \cite{253}. We will call (49) the \textbf{Bona–Odzijewicz–Ratiu equation}. If \(\mathcal{N} = \mathcal{B}(\mathcal{H})\) then \(\mathcal{N}_* \cong \mathcal{G}_1(\mathcal{H})\) and for every \(\rho \in \mathcal{G}_1(\mathcal{H})\) and every \(x, y \in \mathcal{B}(\mathcal{H})\)

\[ \|[y, -\text{ad}^*_x(\rho)]\|_{\mathcal{B}(\mathcal{H})} = -\|[x, y], \rho\|_{\mathcal{B}(\mathcal{H})} = -\text{tr}_\mathcal{H}([x, y], \rho) = \|[x, \rho], y\|_{\mathcal{G}_1(\mathcal{H})}. \]  

(50)

which follows from the fact that \(\mathcal{G}_1(\mathcal{H})\) is an ideal in \(\mathcal{B}(\mathcal{H})\). As a result,

\[ -\text{ad}^*_x(\rho) = [x, \rho], \]  

(51)

and the BOR equation (49) turns to the Lax equation \cite{224}

\[ X_f(\rho) = [D^F_x f, \rho] \quad \forall \rho \in \mathcal{G}_1(\mathcal{H}). \]  

(52)

In particular, a choice of the Hamilton function \(h(\rho) := \text{tr}_\mathcal{H}(H\rho)\), where \(H \in \mathcal{B}(\mathcal{H})\) but is not necessarily self-adjoint, turns (47) to

\[ \frac{d}{dt} \rho(t) = -\text{ad}^*_x h(\rho) = [H, \rho]. \]  

(53)
2.1.3 Quantum Poisson systems

The above equation is derived for a Poisson structure on $\mathcal{N} = \mathfrak{g}_1(\mathcal{H})$ viewed as a holomorphic Banach Poisson manifold. However, the standard construction of unitary dynamics in quantum mechanics makes us to be more interested in the real Banach Poisson manifold $N^{sa}$ (and submanifolds of it that are also subsets of $N^+$), equipped with the Poisson structure coinduced by the action of the Lie algebra $\mathcal{N}^{asa}$ of anti-selfadjoint elements of $N$. More precisely, the set $N^{uni}$ of all unitary elements of a W*-algebra $N$ is a real Banach Lie group and has a real Lie Banach algebra $\text{Lie}(N^{uni}) = N^{asa} := \{ x \in N \mid x = -x^* \}$ with $[x, y] := xy - yx$. The elements of the Banach Lie algebra $N^{asa}$ can be represented by $x \in N^{sa} = iN^{asa}$, using the Lie bracket $\mathcal{N}^{sa} \times \mathcal{N}^{sa} \ni (x, y) \mapsto [x, y] \in N^{sa}$, which corresponds to the commutator $[ix, iy] = iz$ in $N^{asa}$. This algebra has a unique Banach predual, given by $N^{sa} \cong L_1(N) := \{ \phi \in L_1(N) \mid \phi = \phi^* \}$, with an isomorphism $(N^{asa})^* \cong N^{sa}$ defined by duality

$$\mathcal{N}^{sa} \times \mathcal{N}^{sa} \ni (\phi, x) \mapsto \left(\phi, x\right)_{N^{asa} \times N^{asa}} := \phi(x) \in \mathbb{R}. \quad (54)$$

The adjoint representation $\text{Ad}(\mathcal{N}^{uni})$ of a Banach Lie group $\mathcal{N}^{uni}$ on $\text{Lie}(\mathcal{N}^{uni}) = \mathcal{N}^{asa}$, $\text{Ad}(u)x := u x u^* \quad \forall u \in \mathcal{N}^{uni} \forall x \in \mathcal{N}^{sa}$

$$\text{Ad}(u)x := u x u^* \quad \forall u \in \mathcal{N}^{uni} \forall x \in \mathcal{N}^{sa} \quad (55)$$

determine the coadjoint representation $\text{Ad}^* (\mathcal{N}^{uni})$ on $(\mathcal{N}^*)^{sa}$,

$$\mathcal{N}^{asa} \times (\mathcal{N}^*)^{sa} \ni (\phi, x) \mapsto \left[\mathcal{N}^{asa} \times (\mathcal{N}^*)^{sa}\right] := \left[\mathcal{N}^{asa} \times (\mathcal{N}^*)^{sa}\right] \mathcal{N}^{asa} \forall x \in \mathcal{N}^{sa} \forall \phi \in (\mathcal{N}^*)^{sa}. \quad (56)$$

Using these properties, one can show that $\mathcal{N}^{sa}$

$$\mathcal{N}^{sa} \subseteq \mathcal{N}^{sa} \subseteq \text{Ad}^* (\mathcal{N}^{uni}) \quad (57)$$

The space $N^{sa}$ can be equipped with a real Banach smooth manifold structure modelled on itself by the atlas consisting of one chart, which is determined by the identity mapping on $N^{sa}$. As a result, $T_p(N^{sa}) \cong N^{sa}$ $\forall \phi \in N^{sa}$.

So, it is possible to use (40) and (54) to define the BLP structure on $N^{sa}$ by

$$\{ f, k \}(\phi) := i\phi([\mathcal{D}_\phi^F f, \mathcal{D}_\phi^F k]) \quad \forall f, k \in C_c^\infty(N^{asa}; \mathbb{R}) \forall \phi \in N^{sa}. \quad (58)$$

As a result, the Hamilton equation (47) for $h \in C_c^\infty(N^{asa}; \mathbb{R})$ reads

$$\frac{d}{dt} f(\phi(t)) = \{ h, f \}(\phi(t)) = i\phi(\dot{\phi}(t)) \left( [\mathcal{D}_\phi^F h, \mathcal{D}_\phi^F f] \right). \quad (59)$$

The spaces $N^{1+}$, $N^+$ and $(\mathcal{N}^*)^{sa}$ are subsets of $(\mathcal{N}^*)^{sa}$ that are invariant with respect to $\text{Ad}^* (\mathcal{N}^{uni})$. As shown in [27], they decompose into union of orbits of $\text{Ad}^* (\mathcal{N}^{uni})$, which in turn are weak symplectic manifolds, which provides the symplectic foliation of the BLP space $(\mathcal{N}^{sa}, \{ \cdot, \cdot \}_{\mathcal{N}^{sa}})$. Similarly, $(\mathcal{N}^+, \{ \cdot, \cdot \}_{\mathcal{N}^+})$ is invariant with respect to the action of the Banach Lie group $\mathcal{N}^{uni}$ of all invertible elements of $N$. If $N = \mathfrak{g}(\mathcal{H})$ and $\rho \in \mathfrak{g}_1(\mathcal{H})^{sa}$, then the calculation analogous to (50) gives

$$\text{ad}_\rho^* (\rho) = \{ \rho, x \} \forall x \in \mathfrak{g}(\mathcal{H})^{asa} \forall \rho \in \mathfrak{g}_1(\mathcal{H})^{sa}. \quad (60)$$

As a result, the BOR equation (49) on $N^{sa} = \mathfrak{g}_1(\mathcal{H})^{sa}$ takes the form

$$\mathcal{X}_f(\rho) = \{ \rho, \mathcal{D}_\rho^F f \} \quad \forall \rho \in \mathfrak{g}_1(\mathcal{H}), \quad (61)$$

while the Hamilton equation (59) becomes [38]

$$\frac{d}{dt} f(\rho(t)) = i \text{tr}_\mathcal{H} \left( \{ \rho(t), \mathcal{D}_\rho^F h \} \mathcal{D}_\rho^F f \right). \quad (62)$$

Because of the identity

$$\frac{d}{dt} f(\rho(t)) = \text{tr}_\mathcal{H} \left( \mathcal{D}_\rho^F f \frac{d}{dt} \rho(t) \right), \quad (63)$$

24
the equation (62) is equivalent to the **Bôna equation** [36, 187, 38],
\[ \frac{d}{dt} \rho(t) = [\mathcal{D}^F_{\rho(t)}h, \rho(t)]. \]  
(64)

The solutions of (64) are state-dependent unitary operators \( U(\rho, t) \). They do not form a group, but satisfy a cocycle relationship:
\[ U(\rho, t + s) = U((\text{Ad}(U(\rho, t)))(\rho), s)U(\rho, t) \quad \forall t, s \in \mathbb{R}. \]  
(65)

In the special case, when \( h(\rho) = \text{tr}_H(\rho H) \) for \( H \in \mathcal{B}(\mathcal{H})^{sa} = i\mathcal{B}(\mathcal{H})^{asa} \), (64) turns to the **von Neumann equation**
\[ \frac{d}{dt} \rho(t) = [H, \rho(t)]. \]  
(66)

So far we have followed the Bôna–Odzijewicz–Ratiu approach, hence our main object of interest was the real Banach manifold \( \mathcal{N}^{sa} \), equipped with the BLP space structure coinduced by the Banach–Lie algebra \( \mathcal{N}^{asa} \), corresponding to the group \( \mathcal{N}^{uni} \) of unitary elements of \( \mathcal{N} \). However, in principle, a geometric setting for nonlinear dynamics of quantum models can be generated by an arbitrary Banach Lie algebra \( \mathcal{B} \) over \( \mathbb{R} \) such that:

(i) its Banach predual space \( \mathcal{B}^* \), exists, is unique, and is a real Banach Poisson manifold,

(ii) \( \text{ad}^\ast_x(\mathcal{B}^*) \subseteq \mathcal{B}^* \forall x \in \mathcal{B} \),

(iii) there exists a nonempty set \( \mathcal{M}(\mathcal{N}, \mathcal{B}) \subseteq \mathcal{N}^+_\ast \) that is a real BLP submanifold of \( \mathcal{B}^* \).

In what follows, we will call such Banach Lie algebras \( \mathcal{B} \) to be **well-adapted**. For any choice of \( h \in C_0^\infty(\mathcal{M}(\mathcal{N}, \mathcal{B}); \mathbb{R}) \), the pair \( (\mathcal{M}(\mathcal{N}, \mathcal{B}), h) \) will be called a **quantum Poisson system** whenever
\[ \omega^h(\phi) \in \mathcal{M}(\mathcal{N}, \mathcal{B}) \quad \forall \phi \in \mathcal{M}(\mathcal{N}, \mathcal{B}) \quad \forall t \in \mathbb{R}. \]  
(67)

Hence, each quantum Poisson system is determined by a choice of: a space of quantum states \( \mathcal{M}(\mathcal{N}) \subseteq \mathcal{N}^+_\ast \), a Banach Lie algebra \( \mathcal{B} \), a tangent bundle (real Banach manifold) structure on \( \mathcal{M}(\mathcal{N}) \), and a real Fréchet smooth function on \( \mathcal{M}(\mathcal{N}) \), satisfying the conditions (i), (ii), (iii), and (67). The assumptions \( \mathcal{B} \cong \mathcal{N}^{sa} \) and \( \text{T}_{\phi}\mathcal{N}^{sa} := \mathcal{N}^{sa} \forall \phi \in \mathcal{N}^{sa} \) recover the BOR setting completely. Note that a general quantum Poisson system \( (\mathcal{M}(\mathcal{N}, \mathcal{B}), h) \) does not have to be related to any group, so in particular to a group of unitary operators \( \mathcal{N}^{uni} \). The only shared property (securing the backwards compatibility with quantum mechanical setting) is implementation of the Poisson flow on the predual by means of a coinduced action of a Banach–Lie algebra.

### 2.2 Relative modular operators, standard liouvilleans and the GNS bundle

A **weight** on a \( W^\ast \)-algebra \( \mathcal{N} \) is defined as a function \( \omega : \mathcal{N}^+ \to [0, +\infty] \) such that \( \omega(0) = 0 \), \( \omega(x + y) = \omega(x) + \omega(y) \), and \( \lambda \geq 0 \Rightarrow \omega(\lambda x) = \lambda \omega(x) \), with the convention \( 0 \cdot (+\infty) = 0 \). A weight is called: **faithful** iff \( \omega(x) = 0 \Rightarrow x = 0 \); **finite** iff \( \omega(1) < \infty \); **semi-finite** iff a left ideal in \( \mathcal{N} \) given by \( n_\phi := \{ x \in \mathcal{N} \mid \phi(x^a x) < \infty \} \) is weakly-\( a \)-dense in \( \mathcal{N} \); **normal** iff \( \omega(\text{sup} \{ x_i \}) = \text{sup} \{ \omega(x_i) \} \) for any uniformly bounded increasing net \( \{ x_i \} \subseteq \mathcal{N}^+ \). A space of all normal semi-finite weights on a \( W^\ast \)-algebra \( \mathcal{N} \) is denoted \( W(\mathcal{N}) \), while the subset of all faithful elements of \( W(\mathcal{N}) \) is denoted \( W_0(\mathcal{N}) \). Hence, \( \mathcal{N}^+_\ast \subset W(\mathcal{N}) \) and \( \mathcal{N}^+_0 \subset W_0(\mathcal{N}) \). For \( \psi \in W(\mathcal{N}) \), \( \text{supp}(\psi) = \mathbb{I} - \text{sup} \{ P \in \text{Proj}(\mathcal{N}) \mid \psi(P) = 0 \} \).

An element \( \omega \in \mathcal{N}^+_\ast \) is faithful iff \( \text{supp}(\omega) = \mathbb{I} \).

A **representation** of a \( W^\ast \)-algebra \( \mathcal{N} \) is defined as a pair \((\mathcal{H}, \pi)\) of a Hilbert space \( \mathcal{H} \) and a *-homomorphism \( \pi : \mathcal{N} \to \mathfrak{B}(\mathcal{H}) \). A representation \( \pi : \mathcal{N} \to \mathfrak{B}(\mathcal{H}) \) is called: **nondegenerate** iff \( \{ \pi(x)\xi \mid (x, \xi) \in \mathcal{N} \times \mathcal{H} \} \) is dense in \( \mathcal{H} \); **normal** iff it is continuous with respect to the weak-* topologies of \( \mathcal{N} \) and \( \mathfrak{B}(\mathcal{H}) \); **faithful** iff \( \ker(\pi) = \{0\} \). An element \( \xi \in \mathcal{H} \) is called **cyclic** for a \( W^\ast \)-algebra \( \mathcal{N} \subset \mathfrak{B}(\mathcal{H}) \) iff \( \mathcal{N} : \xi := \bigcup_{\xi \in \mathcal{N}} \{ x \xi \} \) is norm dense in \( \mathfrak{B}(\mathcal{H}) \). A representation \( \pi : \mathcal{N} \to \mathfrak{B}(\mathcal{H}) \) is called **cyclic** iff there exists \( \Omega \in \mathcal{H} \) that is cyclic for \( \pi(\mathcal{N}) \). According to the Gel’fand–Naimark–Segal theorem [106, 311] for every pair \((\mathcal{N}, \omega)\) of a \( W^\ast \)-algebra \( \mathcal{N} \) and \( \omega \in \mathcal{N}^{\ast+} \) there exists a triple
(\(\mathcal{H}_\omega, \pi_\omega, \Omega_\omega\)) of a Hilbert space \(\mathcal{H}_\omega\) and a cyclic representation \(\pi_\omega : \mathcal{N} \to \mathcal{B}(\mathcal{H})\) with a cyclic vector \(\Omega_\omega \in \mathcal{H}_\omega\), and this triple is unique up to unitary equivalence. An analogue of this theorem for weights follows the similar construction, but lacks cyclicity. If \(\omega\) is a weight on a \(W^*\)-algebra \(\mathcal{N}\), then there exists the Hilbert space \(\mathcal{H}_\omega\), defined as the completion of \(n_\omega/\ker(\omega)\) in the topology of a norm generated by the scalar product \(\langle \cdot, \cdot \rangle_\omega : n_\omega \times n_\omega \ni (x, y) \mapsto \omega(x^* y) \in \mathbb{C}\).

\[
\mathcal{H}_\omega := \overline{n_\omega/\ker(\omega)} = \overline{\{x \in \mathcal{N} \mid \omega(x^* x) < \infty\}}/\overline{\{x \in \mathcal{N} \mid \omega(x^* x) = 0\}} = \overline{n_\omega/I_\omega},
\]

and there exist the maps

\[
[\cdot]_\omega : n_\omega \ni x \mapsto [x]_\omega \in \mathcal{H}_\omega,
\]

\[
\pi_\omega : \mathcal{N} \ni x \mapsto (y]_\omega \mapsto [xy]_\omega) \in \mathcal{B}(\mathcal{H}_\omega),
\]

such that \([\cdot]_\omega\) is linear, \(\text{ran}([\cdot]_\omega)\) is dense in \(\mathcal{H}_\omega\), and \((\mathcal{H}_\omega, \pi_\omega)\) is a representation of \(\mathcal{N}\). If \(\omega \in \mathcal{W}(\mathcal{N})\) then \((\mathcal{H}_\omega, \pi_\omega)\) is nondegenerate and normal. It is also faithful if \(\omega \in \mathcal{W}_0(\mathcal{N})\).

A standard representation [130] of a \(W^*\)-algebra \(\mathcal{N}\) is defined as a quadruple \((\mathcal{H}, \pi, J, \mathcal{H}^2)\) of a Hilbert space \(\mathcal{H}\), a nondegenerate faithful weakly-\* continuous representation \(\pi : \mathcal{N} \to \mathcal{B}(\mathcal{H})\), a conjugation \(J : \mathcal{H} \to \mathcal{H}\), and a self-polar cone\(^{20}\) \(\mathcal{H}^2 \subseteq \mathcal{H}\), satisfying the conditions

\[
J\pi(\mathcal{N})J = \pi(\mathcal{N})^*, \quad \xi \in \mathcal{H}^2 \Rightarrow J\xi = \xi, \quad \pi(x)J\pi(x)\mathcal{H}^2 \subseteq \mathcal{H}^2, \quad y \in \mathfrak{z}(\pi(\mathcal{N})) \Rightarrow JyJ = y^*.
\]

For any standard representation

\[
\forall \phi \in \mathcal{N}^*_+ \exists! \xi_\phi(\phi) \in \mathcal{H}^2 \forall x \in \mathcal{N} \quad \phi(x) = \langle \xi_\phi(\phi), \pi(x)\xi_\phi(\phi) \rangle_{\mathcal{H}}.
\]

The map \(\xi_\phi : \mathcal{N}^*_+ \to \mathcal{H}^2\) is order preserving. Moreover, \(\xi^{\mathbb{C}}_\phi : \mathcal{H}^2 \to \mathcal{N}^*_+\), defined by \(\xi^{\mathbb{C}}_\phi(\xi)(x) = \langle \xi, \pi(x)\xi \rangle_{\mathcal{H}} \forall x \in \mathcal{N}\), is a bijective norm continuous homomorphism with \((\xi^{\mathbb{C}}_\phi(\xi))^{-1} = \xi_\phi\). For any two standard representations \((\mathcal{H}_1, \pi_1, J_1, \mathcal{H}^2_1)\) and \((\mathcal{H}_2, \pi_2, J_2, \mathcal{H}^2_2)\) of a \(W^*\)-algebra \(\mathcal{N}\) and a given \(\pi\) isomorphism \(\xi : \pi_1(\mathcal{N}) \to \pi_2(\mathcal{N})\), there exists a unique unitary \(u_\xi : \mathcal{H}_1 \to \mathcal{H}_2\) such that \(\xi(x) = u_\xi xu_\xi^* \forall x \in \pi_1(\mathcal{N})\), \(J_2 = u_\xi J_1u_\xi^*\), \(\mathcal{H}^2_2 = u_\xi \mathcal{H}^2_1\). Such \(u_\xi\) will be called a standard unitary equivalence. If \(\phi \in \mathcal{N}^*_+\) then, by means of the Tomita–Takesaki theory [350, 347], the GNS representation associated with \(\phi\) determines a unique conjugation \(J_\phi\), and a weakly-\* continuous group homomorphism \(\sigma^\omega : \mathbb{R} \to \text{Aut}(\mathcal{N})\). An associated \(\mathcal{H}^2\) is given by [73, 18]

\[
\mathcal{H}^2_\phi := \bigcup_{x \in \mathcal{N} \cap n_\phi^*} \{\pi_\phi(x)J_\phi\pi_\phi(x)J_\phi\Omega_\phi\}^{H_{\phi}}.
\]

If \(\mathcal{N} \cong \mathcal{B}(\mathcal{K})\) for some Hilbert space \(\mathcal{K}\) and \(\phi \in \mathcal{W}_0(\mathcal{N})\) is given by \(tr_\mathcal{K}\), then the corresponding GNS Hilbert space \(\mathcal{H}_\phi\) is given by the space of all Hilbert–Schmidt operators,

\[
\mathfrak{G}_2(\mathcal{K}) := \{x \in \mathcal{B}(\mathcal{K}) \mid (tr_\mathcal{K}(x^* x))^{1/2} < \infty\} = n_{tr_\mathcal{K}},
\]

equipped with a scalar product \(\langle x, y \rangle_{\mathfrak{G}_2(\mathcal{K})} := tr_\mathcal{K}(x^* y)\), so that \(\mathfrak{G}_2(\mathcal{K}) \cong \mathcal{K} \otimes \mathcal{K}^*\) as Hilbert spaces. Moreover, \(\mathcal{H}^2_\phi = \mathfrak{G}_2(\mathcal{K})^+\), \(\pi_\phi(x) = \mathcal{L}_x\) (which denotes left multiplication by \(x\)), while \(\xi_\phi : \mathfrak{G}_1(\mathcal{K})^+ \ni \rho \mapsto \rho^{1/2} \in \mathfrak{G}_2(\mathcal{K})^+\). For a given \(W^*\)-algebra \(\mathcal{N}\), \(\phi \in \mathcal{W}(\mathcal{N})\), and \(\omega \in \mathcal{W}_0(\mathcal{N})\) the map

\[
R_{\phi, \omega} : [x]_\omega \mapsto [x^*]_\phi \quad \forall x \in n_\omega \cap n_\phi^*
\]

is a densely defined, closable antilinear operator. Its closure admits a unique polar decomposition

\[
\overline{R_{\phi, \omega}} = J_{\phi, \omega} \Delta_{\phi, \omega}^{1/2},
\]

\(^{20}\)A subspace \(\mathcal{D}\) of a Hilbert space \(\mathcal{H}\) is called a self-polar cone iff \(\lambda \xi \in \mathcal{D} \forall \xi \in \mathcal{D} \forall \lambda \geq 0\) and \(\mathcal{D} = \{\xi \in \mathcal{H} \mid \langle \xi, \xi \rangle_{\mathcal{H}} \geq 0 \forall \xi \in \mathcal{D}\}\).
where $J_{\phi,\omega}$ is a conjugation operator, called \textit{relative modular conjugation}, while $\Delta_{\phi,\omega}$ is a positive self-adjoint operator on $\text{dom}(\Delta_{\phi,\omega}) \subseteq \mathcal{H}$, with $\text{supp}(\Delta_{\phi,\omega}) = \text{supp}(\phi)\mathcal{H}$, called a \textit{relative modular operator} \cite{17, 73, 82}. Given $\omega \in W_0(\mathcal{N})$, $\Delta_{\omega,\omega} =: \Delta_{\omega}$ implements the action of the Tomita–Takesaki (modular) automorphism $\sigma^\omega$ by

$$\pi_{\omega}(\sigma^\omega_t(x)) = \Delta_{\omega}^{it}\pi_{\omega}(x)\Delta_{\omega}^{-it}. \quad (77)$$

If $\mathcal{N} \cong \mathcal{B}(\mathcal{H})$, $\phi = \text{tr}_\mathcal{H}(\rho \cdot)$, $\omega = \text{tr}_\mathcal{H}(\rho^* \cdot)$, and $R_x$ denotes right multiplication by $x \in \mathcal{B}(\mathcal{H})$, then $\Delta_{\phi,\omega} = \mathcal{L}_{R_{\rho_x}}(R_{\rho_x}^{-1})$.

For every $\phi, \omega \in W_0(\mathcal{N})$ the relative modular conjugation $J_{\phi,\omega}$ determines a unique unitary operator $J_{\phi,\omega} : \mathcal{H}_\omega \to \mathcal{H}_\phi$, such that

$$\pi_{\omega}(\phi(x)) = V_{\phi,\omega}\pi_{\omega}(x)V_{\phi,\omega}^*, \quad (78)$$

$$V_{\phi,\omega}(\mathcal{H}_\omega) = \mathcal{H}_\phi^c,$$  

$$V_{\phi,\omega}J_{\omega,\omega} = J_{\phi,\omega}V_{\phi,\omega}. \quad (80)$$

We will call $V_{\phi,\omega}$ \textit{standard unitary transition} between $\mathcal{H}_\omega$ and $\mathcal{H}_\phi$. It is a standard unitary equivalence of a $*$-isomorphism $\zeta_{\phi,\omega} : \pi_{\omega}(\mathcal{N}) \to \pi_{\phi}(\mathcal{N})$ determined by the condition $\zeta_{\phi,\omega} \circ \pi_{\omega} = \pi_{\phi}$. Thus, if $\omega, \phi \in \mathcal{N}^+_0$, then $V_{\phi,\omega}$ provides a default unitary mapping between the corresponding GNS Hilbert spaces and representations.

Given any group $G$, a \textit{representation} of $G$ in the group $\text{Aut}(\mathcal{N})$ of $*$-automorphisms of a $\mathcal{W}^*$-algebra $\mathcal{N}$ is a map $\alpha : G \ni g \mapsto \alpha(g) =: \alpha_g \in \text{Aut}(\mathcal{N})$ which is a \textit{group homomorphism}, that is,

1) $\alpha(e) = \text{id}_{\mathcal{N}},$

2) $\alpha(g_1) \circ \alpha(g_2) = \alpha(g_1 \circ g_2) \ \forall g_1, g_2 \in G,$

where $e$ denotes the neutral element of $G$. A group $G$ is called: \textit{topological} iff it is also a topological space and a map $G \times G \ni (g_1, g_2) \mapsto g_1 \circ g_2^{-1} \in G$ is continuous for all $g_1, g_2 \in G$; \textit{locally compact} iff it is topological and $e \in G$ has a compact topological neighbourhood. For any $\mathcal{W}^*$-algebra $\mathcal{N}$, $\text{Aut}(\mathcal{N})$ is a topological group with respect to \textit{weak-* topology} on $\text{Aut}(\mathcal{N})$, defined by the collection of neighbourhoods \cite{348}\n
$$N_{(\omega_i)}(\alpha) := \{\zeta \in \text{Aut}(\mathcal{N}) \mid |\omega_i \circ \alpha - \omega_i \circ \zeta|_{\mathcal{N}} < 1, \ |\omega_i \circ \alpha^{-1} - \omega_i \circ \zeta^{-1}|_{\mathcal{N}} < 1\}, \quad (81)$$

where $\{\omega_i\} \subseteq \mathcal{N}^*_i$, $i \in \{1, \ldots, n\}$, $n \in \mathbb{N}$. A triple $(\mathcal{N}, G, \alpha)$ of a $\mathcal{W}^*$-algebra, locally compact group $G$, and a representation $\alpha : G \to \text{Aut}(\mathcal{N})$ is called a $\mathcal{W}^*$-\textit{dynamical system} (or a $\mathcal{W}^*$-\textit{covariant system}) iff $\alpha$ is continuous in the weak-* topology of $\text{Aut}(\mathcal{N})$. This condition is equivalent to the continuity of the map $G \ni g \mapsto \alpha_g(x) \in \mathcal{N}$ in the weak-* topology of $\mathcal{N}$ for any $x \in \mathcal{N}$, that is, to

$$G \ni g \mapsto \phi(\alpha_g(x)) \in \mathcal{C} \text{ is a continuous function } \forall x \in \mathcal{N}, \quad (82)$$

and such $\alpha$ is called a \textit{weakly-* continuous} representation. Uniqueness of a predual of a $\mathcal{W}^*$-algebra $\mathcal{N}$ allows to define isometries $\alpha_* \in \mathcal{N}_*$ that uniquely correspond to the elements $\alpha \in \text{Aut}(\mathcal{N})$, and to define the isometries of $\mathcal{N}_*$ uniquely corresponding to representations $\alpha : G \to \text{Aut}(\mathcal{N})$:

$$\|\alpha_g(x) - \phi(x)\|_{\mathcal{N}_*} = 0 \quad \forall \phi \in \mathcal{N}_*, \forall g \in G. \quad (84)$$

A \textit{unitary implementation} of a representation $\alpha : G \to \text{Aut}(\mathcal{N})$ in a given representation $\pi : \mathcal{N} \to \mathcal{B}(\mathcal{H})$ is defined as a map $u : G \ni g \mapsto u(g) \in \mathcal{B}(\mathcal{H})^{\text{uni}}$ that determines a family $\{u(g) \mid g \in G\}$ of unitary operators satisfying the \textit{covariance equation}

$$\pi(\alpha_g(x)) = u(g)\pi(x)u(g)^* \quad \forall x \in \mathcal{N} \ \forall g \in G. \quad (85)$$
The condition (85) alone does not determine \( \{ u(g) \mid g \in G \} \) uniquely. The setting of \( \mathcal{W}^* \)-algebras admits a remarkable solution to this problem: every pair of a \( \mathcal{W}^* \)-dynamical system \((\mathcal{N}, \mathbb{R}, \alpha)\) and a standard representation \((\mathcal{H}, \pi, J, \mathcal{H}^2)\) determines uniquely a corresponding unitary implementation together with a unique self-adjoint generator of this family of unitaries. This generator is called a standard liouvillean\(^{21}\). It is not called ‘hamiltonian’, because in general its spectrum may be not bounded from any side, while the notion of ‘hamiltonian’ is usually understood as referring to a self-adjoint operator that generates a strongly continuous group of unitary operators and has a nonnegative (or at least bounded from below) spectrum\(^{22}\). Moreover, as opposed to hamiltonian, the construction of standard liouvillean for a given \( \mathcal{W}^* \)-dynamical system does not require any additional analytic conditions that constrain derivation to an ‘integrable’ infinitesimal generator. This way the \( \mathcal{W}^* \)-algebraic approach makes the notion of a hamiltonian less relevant than the notion of a liouvillean.

For any \( \mathcal{W}^* \)-algebra \( \mathcal{N} \), the unique predualisation of action of \( \alpha \in \text{Aut}(\mathcal{N}) \) can be connected with the uniqueness property of representation of elements of \( \mathcal{N}_*^+ \) in terms of a standard cone of a standard representation \((\mathcal{H}, \pi, J, \mathcal{H}^2)\) of \( \mathcal{N} \): any \( \alpha \in \text{Aut}(\mathcal{N}) \) defines a unique map \( u : \mathcal{H}^2 \to \mathcal{H}^3 \) by

\[
\forall \phi \in \mathcal{N}_*^+.
\]

This map is linear, can be extended to a unitary operator on all \( \mathcal{H} \), and satisfies

\[
\forall x \in \mathcal{N}.
\]

This leads to a question, whether it is possible to generate this way a standard unitary implementation of a given representation \( \alpha : G \to \text{Aut}(\mathcal{N}) \). The answer is in the affirmative, and was established by Haagerup [130] (the special cases of this result were obtained earlier in [188, 189, 140, 133, 267]). If \((\mathcal{H}, \pi, J, \mathcal{H}^2)\) is a standard representation of a \( \mathcal{W}^* \)-algebra \( \mathcal{N} \), then there exists a unique strongly continuous unitary implementation \( V_\alpha(g) \) of \( \alpha \) satisfying

\[
V_\alpha(g)\mathcal{H}^3 = \mathcal{H}^2, \quad JV_\alpha(g) = V_\alpha(g)J.
\]

Such family \( \{ V_\alpha(g) \mid g \in G \} \) is called a standard unitary implementation of \( \alpha \).

Thus, if \((\mathcal{N}, \mathbb{R}, \alpha)\) is a \( \mathcal{W}^* \)-dynamical system with \( \mathcal{N} \) in standard form \((\mathcal{H}, \pi(\mathcal{N}), J, \mathcal{H}^2)\), then from the theorems of Haagerup and Stone [335, 336, 362] it follows that there exists a unique strongly continuous group of unitaries \( \{ V_\alpha(t) \mid t \in \mathbb{R} \} \subseteq \mathcal{B}(\mathcal{H})^{\text{uni}} \), and a unique self-adjoint operator \( K^\alpha \) on \( \mathcal{H} \), called standard liouvillean, such that \( V_\alpha(t) \) is a strongly continuous unitary implementation of \( \alpha \) and for every \( t \in \mathbb{R} \)

\[
\begin{align*}
i) \quad V_\alpha(t) &= e^{-itK^\alpha}, \\
ii) \quad e^{-itK^\alpha}\mathcal{H}^3 &= \mathcal{H}^2, \\
iii) \quad JK^\alpha + K^\alpha J &= 0.
\end{align*}
\]

The definition of a standard liouvillean \( K^\alpha \) does not depend on any choice of \( \omega \in \mathcal{N}_*^+ \) or \( \omega \in W(\mathcal{N}) \): it depends only on a \( \mathcal{W}^* \)-dynamical system and a standard representation of \( \mathcal{W}^* \)-algebra. If \( \mathcal{N} \) is semi-finite, \((\mathcal{H}, \pi, J, \mathcal{H}^2)\) is its standard representation, \((\mathcal{N}, \mathbb{R}, \alpha)\) is a \( \mathcal{W}^* \)-dynamical system, \( H \in \pi(\mathcal{N})^{sa} \), and \( \{ U(t) := e^{-itH} \in \pi(\mathcal{N}) \mid t \in \mathbb{R} \} \) is a strongly continuous group of unitary operators such that

\[
e^{itH}\pi(x)e^{-itH} = \pi(\alpha_t(x)) \quad \forall x \in \mathcal{N} \quad \forall t \in \mathbb{R},
\]

then the standard liouvillean reads [44, 165]

\[
K^\alpha = H - JHJ = [H, \cdot].
\]

\(^{21}\)It would be however more precise to call it quantum koopmanian, because in the commutative setting (of statistical mechanics and probability measures) the ‘liouvillean operator’ (defined by the Poisson bracket) acts on elements of \( L_1(X, \tilde{\mathcal{U}}(X), \tilde{\mu}) \), while it is the ‘koopmanian operator’ [201, 363, 364] that acts on the positive cone of \( L_1(X, \tilde{\mathcal{U}}(X), \tilde{\mu}) \).

\(^{22}\)E.g., ʻone of the most important principles of quantum field theory, ensuring the stability, demands that the energy should have a lower boundʻ [127].

28
Following Odzijewicz and Sliżewska [256], consider a bundle $\epsilon: V \to \mathcal{N}_0^+$, where
\[ V := \{(x, \omega) \in \mathcal{N} \times \mathcal{N}_0^+ \mid x \text{supp}(\omega) = x\}, \tag{92} \]
and the bundle projection $\epsilon$ is given by a restriction of the cartesian product projection $\mathcal{N} \times \mathcal{N}_0^+ \to \mathcal{N}_0^+$ to $V$. Because $V_\omega := \epsilon^{-1}(\omega) = \text{supp}(\omega) \forall \omega \in \mathcal{N}_0^+$, the scalar product
\[ V_\omega \times V_\omega \ni (x, y) \mapsto \langle x, y \rangle_\omega := \left\langle \omega, x^* y \right\rangle_{\mathcal{N} \times \mathcal{N}} \in \mathbb{C} \tag{93} \]
is nondegenerate. Moreover, $\langle x, x \rangle_\omega = 0 \iff x \in \mathcal{N}(\mathbb{I} - \text{supp}(\omega))$. The completion $\hat{V}_\omega$ of $V_\omega$ under the norm generated by $\langle \cdot, \cdot \rangle_\omega$ determines a bundle $\mathcal{H}\mathcal{N}_0^+ := \hat{V} \to \mathcal{N}_0^+$ of Hilbert spaces, which the authors of [256] call the Gel'fand–Naimark–Segal bundle (the notion of the GNS bundle was earlier alluded in [164, 66]).

While (73) secures that the GNS representation is a standard representation whenever $\phi \in \mathcal{N}_0^+$, it doesn’t have to be in more general case. Thus, in order to be sure that our use of GNS bundle coincides with the necessary conditions for Haagerup’s theorem, we will restrict our discussion in multiple places of this paper to subsets and submanifolds of $\mathcal{N}_0^+$. We consider this restriction to be nonoptimal, but in order to work it out in larger generality, we would have to work with a different bundle of Hilbert spaces. Restriction to $\mathcal{N}_0^+$ allows us to use standard unitary transitions $V_{\omega, \omega}$ to map between Hilbert spaces, at the expense of consideration of unitarily equivalent representations only. Whenever the assumption of restriction to $\mathcal{N}_0^+$ is made, it implies restriction of considerations to countably finite $W^*$-algebras, because only for them $\mathcal{N}_0^+ \neq \emptyset$.

### 2.3 Case study: Algebraic hamiltonian vector fields

The BLP structure of $\mathcal{N}$ and $\mathcal{N}_0\text{sa}$ allows to introduce and analyse the temporal evolution on $\mathcal{N}_0^+$ by means of the hamiltonian vector field and the Hamilton equation. On the other hand, for any $W^*$-dynamical system $(\mathcal{N}, R, \alpha)$ one can predualise the representation $\alpha : R \ni t \mapsto \alpha_t \in \text{Aut}(\mathcal{N})$ obtaining the family $\{\alpha_t^* \mid t \in \mathbb{R}\}$ of norm continuous isometries $\alpha_t^* := (\alpha_t)^*: \mathcal{N} \to \mathcal{N}$, which in turn can be analysed by means of a unique self-adjoint standard liouvillean operator $K^\alpha$ that generates a unitary evolution in $L_2(\mathcal{N})$ leaving $L_2(\mathcal{N})^+$ invariant. The virtue of a geometric description in terms of hamiltonian vector field is that it allows for an analysis of the local differential structure of temporal evolution in terms of a local Poisson flow and tangent space. However, it does not guarantee the existence of global flow. On the other hand, an algebraic description in terms of a predualised representation $\alpha_t$ and an associated standard liouvillean $K^\alpha$ guarantees the existence of a global flow on $\mathcal{N}_0^+$, but it is not necessarily a Poisson flow and it is not related to a tangent space, thus it does not allow (in general) for a refined smooth geometric description. This leads us to single out the class of evolutions on $\mathcal{N}_0^+$ (and $\mathcal{N}_0\text{sa}$) that satisfy both conditions.

The isometries $\alpha_t^*$ of $\mathcal{N}$ that are also the Poisson flows leaving $\mathcal{N}_0\text{sa}$ invariant are characterised as solutions of the equation (45)
\[ \{f \circ \alpha_t^*, k \circ \alpha_t^*{\mathcal{N}}_0\text{sa} = \{f, k\}_\mathcal{N}_0\text{sa} \circ \alpha_t^* \forall f, k \in C_0^F(\mathcal{N}_0\text{sa}; \mathbb{R}) \forall t \in \mathbb{R}, \tag{94} \]
which gives, by (58),
\[ \phi([\mathcal{D}_0^F(f \circ \alpha_t^*), \mathcal{D}_0^F(k \circ \alpha_t^*)]) = (\alpha_t^*(\phi))([\mathcal{D}_0^F(\alpha_t^*(\phi)), \mathcal{D}_0^F(\alpha_t^*(\phi))k]), \tag{95} \]
\[ 0 = \phi([\mathcal{D}_0^F(f \circ \alpha_t^*), \mathcal{D}_0^F(k \circ \alpha_t^*)] - \alpha_t([\mathcal{D}_0^F(\alpha_t^*(\phi)f), \mathcal{D}_0^F(\alpha_t^*(\phi))k]]). \tag{96} \]
Hence, the predualisation $\alpha_t$ of a weakly-\ast continuous representation $\alpha : \mathbb{R} \to \text{Aut}(\mathcal{N})$ is a Poisson flow on $(\mathcal{N}_0\text{sa}, \{\cdot, \cdot\})$ iff $\alpha$ satisfies
\[ \phi((\text{id}_\mathcal{N} - \alpha_t([\mathcal{D}_0^F(\alpha_t^*(\phi)f), \mathcal{D}_0^F(\alpha_t^*(\phi))k]]) = 0 \forall \phi \in \mathcal{N}_0\text{sa} \forall f, k \in C_0^F(\mathcal{N}_0\text{sa}; \mathbb{R}) \forall t \in \mathbb{R}. \tag{97} \]
We will call (97) the **Poisson compatibility condition** (PC$_1$). Let $(\mathcal{N}, R, \alpha)$ be a $W^*$-dynamical system satisfying the Poisson compatibility condition. Then the Poisson flow $\alpha_t|_\mathcal{N}_0\text{sa}$ is generated by the Hamilton function $h^\alpha \in C_0^F(\mathcal{N}_0\text{sa}; \mathbb{R})$ according to (47),
\[ \frac{d}{dt}f_t = \{h^\alpha, f_t\}, \quad f_t(x) := f(\alpha_t^*(x)) \forall t \in \mathbb{R} \forall x \in \mathcal{N}, \forall f \in C_0^F(\mathcal{N}_0\text{sa}; \mathbb{R}), \tag{98} \]
which determines the corresponding unique Hamiltonian vector field $\mathfrak{x}_{h^\omega} \in T\mathcal{N}_{\omega}^{\text{sa}}$ by means of the BOR equation (49),

$$\mathfrak{x}_{h^\omega}(\phi) = -\text{ad}_{\mathfrak{g}_{\omega}h^\omega}(\phi) = \mathcal{L}_{\mathfrak{g}_{\omega}h^\omega}(\phi) - 2 \mathfrak{h}_{\mathfrak{g}_{\omega}h^\omega}(\phi) \quad \forall \phi \in \mathcal{N}_{\omega}^{\text{sa}}. \tag{99}$$

We will call $\mathfrak{x}_{h^\omega}$ an **algebraic Hamiltonian vector field**.

Now, let us recall from Section 2.2 that, by the Haagerup theorem, each pair of a W*-dynamical system $(\mathcal{N}, \mathbb{R}, \alpha)$ and a standard representation $(\mathcal{H}, \pi, J, \mathcal{H}^2)$ of $\mathcal{N}$ determines a unique self-adjoint generator $K^\alpha$ of a unitary implementation of $\alpha$ in $\mathfrak{B}(\mathcal{H})$ satisfying the condition $e^{-itK^\alpha}\mathcal{H}^2 \subseteq \mathcal{H}^2$. By means of (72), this condition expresses the requirement that $\alpha_\omega(\mathcal{N}^+, \omega) \subseteq \mathcal{N}^+$ (if formulated in terms of Kosaki’s canonical representation, for which $\mathcal{H}^2 = L_2(\mathcal{N})^+$, this condition is just an $L_2(\mathcal{N})$ version of $L_1(\mathcal{N})^+ = \mathcal{N}^+$ invariance under $\alpha$). If $\omega \in \mathcal{N}_{\omega}^{\text{sa}}$, then the GNS representation, $(\mathcal{H}_\omega, \pi_\omega, \Omega_\omega)$, is also a standard representation $(\mathcal{H}_\omega, \pi_\omega, J_\omega, \mathcal{H}^+_{\omega})$, so we can apply Haagerup’s theorem to the fibres of the GNS bundle $\mathcal{H}\mathcal{N}_{\omega}^{\text{sa}}$ restricted to the submanifold $\mathcal{N}^+_{\omega}$, $\epsilon : \mathcal{H}\mathcal{N}^+_{\omega} \rightarrow \mathcal{N}^+_{\omega}$. Because $\text{supp}(\omega) = \mathbb{I}$ for each $\omega \in \mathcal{N}^+_{\omega}$, the bundle projection $\epsilon$ reduces in this case to a cartesian product projection.

Orbits of any Poisson flow leave $\mathcal{N}^+_{\omega} \subseteq \mathcal{N}_{\omega}^{\text{sa}}$ invariant [38, 27, 287], while $\alpha^t_\omega$ is norm preserving, so the restrictions of Poisson compatible isometries $\alpha^t_\omega$ to $\mathcal{N}^+_{\omega}$ are automorphisms of this space. As a result, we obtain a remarkable geometric correspondence: every weakly-\(*\) continuous representation $\alpha : \mathbb{R} \ni t \mapsto \alpha_t \in \text{Aut}(\mathcal{N})$ satisfying the Poisson compatibility condition (97) determines a unique globally integrable Hamiltonian vector field $\mathfrak{x}_{h^\omega} \in T\mathcal{N}_{\omega}^{\text{sa}}$ and a family of standard liouvillean operators $\mathcal{N}^+_{\omega} \ni \omega \mapsto K_\omega^\alpha \in (\text{Lin}(\mathcal{H}_\omega))^{\text{sa}}$ acting pointwise on the GNS bundle of Hilbert spaces. In other words, the family $\{\alpha_t \in \text{Aut}(\mathcal{N}) \mid t \in \mathbb{R}\}$ of Poisson compatible, weakly-\(*\) continuous automorphisms of a W*-algebra $\mathcal{N}$ is uniquely represented in the tangent vector bundle $T\mathcal{N}_{\omega}^{\text{sa}} \rightarrow \mathcal{N}_{\omega}^{\text{sa}}$ (and, by linearity, also in $T\mathcal{N}^+_{\omega} \rightarrow \mathcal{N}^+_{\omega}$), as well as on the GNS Hilbert bundle $\mathcal{H}\mathcal{N}^+_{\omega} \rightarrow \mathcal{N}^+_{\omega}$.

Due to uniqueness property (72) of the embedding $\zeta_\omega : \mathcal{N}^+_{\omega} \ni \omega \mapsto \zeta_\omega(\omega) \in \mathcal{H}^2$ of any standard representation $(\mathcal{H}, \pi, J, \mathcal{H}^2)$, this means that the embedding of a trajectory generated by $\alpha^t_\omega$ on $\mathcal{N}^+_{\omega}$ to $\mathcal{H}_\omega$ for any $\phi \in \mathcal{N}^+_{\omega}$ coincides with the evolution in $\mathcal{H}^2_\omega$ generated by $e^{-itK_\omega^\alpha}$. Hence, the Hamiltonian flow $\mathfrak{w}_t^{\alpha}_{\phi}$ of $\mathfrak{x}_{h^\omega}$ on $\mathcal{N}^+_{\omega}$ from $\phi(0)$ to $\phi(t)$ can be always represented as liouvillean evolution

$$e^{-itK_\phi^\alpha(t)}\mathfrak{w}_t^{\alpha}(\phi(0)) = \mathfrak{w}_t^{\alpha}(\phi(t)) = : \Omega_{\phi(t)}, \tag{100}$$

where by $\zeta_\omega(\omega)$ we denote the standard representative of $\omega \in \mathcal{N}^+_{\omega}$ in the positive cone $\mathcal{H}^+_{\omega}$ of the GNS representation Hilbert space of $\psi \in \mathcal{N}^+_{\omega}$.

If $\mathcal{N} = \mathfrak{B}(\mathcal{H})$, $\rho \in \mathfrak{B}(\mathcal{H})^{\text{uni}}$, and the weakly-\(*\) continuous representation $\alpha : \mathbb{R} \rightarrow \text{Aut}(\mathfrak{B}(\mathcal{H}))$ is unitary (that is, $\alpha_t = \text{Ad}(u(t))$ with $u(t) \in \mathfrak{B}(\mathcal{H})^{\text{uni}} \forall t \in \mathbb{R}$), then the algebraic Hamiltonian vector field can be expressed by the von Neumann equation (66), while the corresponding liouvillean evolution $\rho(t) = e^{-itK^\alpha}\rho(0)$ in $\mathfrak{B}(\mathcal{H}) \cong \mathcal{H} \otimes \mathcal{H}^*$ is a solution of the equation

$$\frac{d}{dt}\rho(t) = -iK^\alpha \rho(t), \tag{101}$$

which gives (91). In this sense, the Poisson compatibility condition (97) extends the equivalence between the algebraic (liouvillean operator) and geometric (Hamiltonian vector) descriptions of temporal evolution of quantum states to the general W*-dynamical systems. In the next Section we will investigate how standard liouvillean can be used to encode the perturbation of Poisson flow by additional geometric structures over state space, beyond the realms of W*-dynamical systems.

### 2.4 Relative entropy, Norden–Sen geometry, and noncommutative Orlicz spaces

#### 2.4.1 Distances, Norden–Sen geometries, and geodesic free falls as entropic projections

A pair $(\nabla, \nabla^\dagger)$ of two affine connections over a smooth manifold $\mathcal{M}$ will be called **Norden–Sen dual** with respect to a riemannian metric $g$ on $\mathcal{M}$, if [313, 314, 315, 249, 250, 251]

$$g(\nabla_u v, w) + g(v, \nabla^\dagger_u w) = u(g(v, w)) \forall u, v, w \in T\mathcal{M}, \tag{102}$$

30
which is equivalent to
\[ g(t_u \nabla u, t_v \nabla v) = g(u, v) \] (103)
for all \( u, v \in T_M \) and for all curves \( c : \mathbb{R} \to [r_1, r_2] \to M \) (the symbol \( t^c \nabla \) denotes a parallel transport along \( c \) that is determined by an affine connection \( \nabla \)). The quadruple \((M, g, \nabla, \nabla^\dagger)\) is called a \textbf{Norden–Sen geometry}. A riemannian geometry is characterised as a Norden–Sen geometry with \( \nabla = \nabla^\dagger \).

Given a set \( M \), we define a \textbf{distance} on \( M \) as a function \( D : M \times M \to [0, \infty] \) such that \( D(\phi, \omega) = 0 \iff \omega = \phi \). Eguchi \([94, 95, 96]\) showed that for any smooth manifold \( M \) and any smooth distance \( D \) on \( M \) that satisfies
\[ \mathcal{D}_v^{|p} \mathcal{D}_w^{|p} D(p, q)|_{q=p} \in [0, \infty][\forall p \in M \forall v \in T_p M \setminus \{0\}], \] (104)
where \( \mathcal{D}_v^{|p} \) denotes here the Gâteaux derivative at \( p \in M \) in the direction \( v \in T_p M \), the distance \( D \) determines a riemannian metric \( g \) and a pair of affine connections \((\nabla, \nabla^\dagger)\) on \( M \), given by the \textbf{Eguchi equations}
\[ g_{\phi}(u, v) := -\mathcal{D}_u^{|\phi} \mathcal{D}_v^{|\phi} D(\phi, \omega)|_{\omega=\phi}, \] (105)
\[ g_{\phi}(\nabla u, \omega v) := -\mathcal{D}_u^{|\phi} \mathcal{D}_w^{|\phi} D(\phi, \omega)|_{\omega=\phi}, \] (106)
\[ g_{\phi}(v, \nabla^\dagger \omega) := -\mathcal{D}_u^{|\phi} \mathcal{D}_w^{|\phi} D(\phi, \omega)|_{\omega=\phi}. \] (107)

Every quadruple \((M, g, \nabla, \nabla^\dagger)\) determined in this way is a Norden–Sen geometry such that both \( \nabla \) and \( \nabla^\dagger \) are torsion-free. A torsion-free Norden–Sen geometry will be called an \textbf{Eguchi geometry}. While in riemannian geometry the affine connection is determined by the riemannian metric, in the Eguchi geometry the triple of riemannian metric and two Norden–Sen dual affine connections are determined by the distance. The Levi-Civita connection \( \nabla \) of an associated riemannian geometry \((M, g)\) satisfies \( \nabla = (\nabla + \nabla^\dagger)/2 \). In this sense, the Eguchi geometry (based on the nonsymmetric distance) provides a generalisation of a riemannian geometry and cartesian geometry, including all of their main notions: distance, length, parallelity and orthogonality. Generalisation of the cartesian distance is provided by the distance \( D \), the induced riemannian metric \( g \) provides the generalisation of orthogonality and length, while the induced torsion-free Norden–Sen dual connections \((\nabla, \nabla^\dagger)\) provide a generalisation of parallelity.\(^{23}\) The invariance of length under parallel transport that characterises riemannian geometry is weakened to covariance in the sense of (103).

If both affine connections of a Norden–Sen geometry are flat and torsion-free, then it is called a \textbf{dually flat geometry} \([246, 7, 9]\). If dim \( M =: n < \infty \), then every dually flat geometry \((M, g, \nabla, \nabla^\dagger)\) determines a unique pair of affine immersions \( \Psi : M \to \mathbb{R} \) and \( \Psi^L : M \to \mathbb{R} \) such that
\[ g_{ij}(\rho(\theta)) = \frac{\partial^2 \Psi(\rho(\theta))}{\partial \theta^i \partial \theta^j}, \] (108)
\[ g_{ij}(\rho(\eta)) = \frac{\partial^2 \Psi^L(\rho(\eta))}{\partial \eta^i \partial \eta^j}, \] (109)
where \( \{\theta^i\} \) is a coordinate system such that \( \Gamma^j_{ij}(\rho(\theta)) = 0 \ \forall \rho \in M \) and \( \Gamma^j_{ij}(\rho(\eta)) = 0 \ \forall \rho \in M \) \([83, 221, 222, 240]\). Conversely \([7]\), if there exists a convex function \( \Psi \) such that its hessian (matrix of second derivatives) determines pointwise a riemannian metric, then there exists a pair of coordinate systems \( \{\theta^i\} \) and \( \{\eta^i\} \) and a convex function \( \Psi^L : M \to \mathbb{R} \) satisfying the above properties. The dual flatness of a pair \((\theta, \eta)\) of coordinate systems is equivalent to the orthogonality of their tangent vectors at \( q \) with respect to the riemannian metric \( g \) at \( q \),
\[ g_q \left( (T_q \theta)^{-1} \left( \frac{\partial}{\partial \theta^i} \right), (T_q \eta)^{-1} \left( \frac{\partial}{\partial \eta^j} \right) \right) = \delta^i_j \ \forall q \in M. \] (110)

\(^{23}\)The idea that \( D \) should be considered as generalisation of the cartesian distance, while the connection \( \nabla \) associated to a projection by means of \( D \) should be considered as a proper generalisation of parallelity (at least in the setting of statistical manifolds) is due to Chencov \([53, 57]\).
The transition between these two formulations in the real finite dimensional case is provided by means of bijective Legendre transformation $L_\Psi : \Theta \to \Xi$, which acts between suitable open subsets $\Theta \subset \mathbb{R}^n$ and $\Xi \subset \mathbb{R}^n$, and is given by the gradient,

$$L_\Psi : \Theta \ni \theta \mapsto \eta := \nabla \Psi(\theta) \in \Xi.$$  \hspace{1cm} (111)

In the coordinate-dependent form this reads

$$\eta_i = (L_\Psi(\theta))_i := \frac{\partial \Psi(\theta)}{\partial \theta^i},$$  \hspace{1cm} (112)

$$\theta^i = (L_\Psi^{-1}(\eta))^i := \frac{\partial \Psi^L(\eta)}{\partial \eta_i},$$  \hspace{1cm} (113)

whenever the duality pairing is given by

$$\langle \cdot, \cdot \rangle_{\mathbb{R}^n \times \mathbb{R}^n} : \mathbb{R}^n \times \mathbb{R}^n \ni (\theta, \eta) \mapsto \theta \cdot \eta^\top := \sum_{i=1}^n \theta^i \eta_i \in \mathbb{R}.$$  \hspace{1cm} (114)

The Eguchi equations applied to the distance

$$D_\Psi(\rho, \sigma) := \Psi(\rho) - \Psi^L(\sigma) - \sum_{i=1}^n \theta^i(\rho) \eta^i(\sigma)$$  \hspace{1cm} (115)

yield $(\mathcal{M}, g^{D_\Psi}, \nabla^\Psi, \nabla^\Psi^\top) = (\mathcal{M}, g, \nabla, \nabla^\top)$. We will call such $D_\Psi$ a canonical Brègman distance of a dually flat geometry $(\mathcal{M}, g, \nabla, \nabla^\top)$. A riemannian metric $g$ on an affine manifold $(\mathcal{M}, \nabla)$ with flat $\nabla$ is said to be hessian, and denoted $g^\Psi$, iff there exists a smooth function $\Psi : \mathcal{M} \to \mathbb{R}$ such that

$$g(u, v) = (\nabla_u d\Psi)(v) \quad \forall u, v \in T\mathcal{M}.$$  \hspace{1cm} (116)

Such triple $(\mathcal{M}, g, \nabla)$ will be called a hessian geometry [322] (see also [216, 359, 91]). The function $\Psi$ in (116) is the same as in the representation of $g_{ij}(\rho(\theta))$ above, and

$$g(u, v) = (\nabla_u^g d\Psi^L)(v) \quad \forall u, v \in T\mathcal{M}.$$  \hspace{1cm} (117)

Hence, given a riemannian manifold $(\mathcal{M}, g)$ and an affine connection $\nabla$ on $\mathcal{M}$ the following conditions are equivalent [321, 323, 322]: (1) $(\mathcal{M}, g, \nabla)$ is a hessian geometry; (2) $(\mathcal{M}, g, \nabla, 2\nabla - \nabla)$ is a dually flat geometry.

Let $(\mathcal{M}, g, \nabla, \nabla^\top)$ be a dually flat geometry, and let $\Omega \subseteq \mathcal{M}$ be $\nabla^\top$-affine (i.e., there exists a coordinate system $\{\eta^i\}$ on $\Omega$ such that $\Gamma_{ij}^k(\rho(\eta)) = 0 \ \forall \rho \in \Omega$) and $\nabla^\top$-convex (i.e. $\forall \rho_1, \rho_2 \in \Omega \implies \nabla^\top$-geodesics in $\Omega$ connecting them). Then there exists a unique entropic projection

$$\mathcal{M} \ni \rho \mapsto \forall_\mathcal{Q}(\rho) := \text{arg inf}_{\sigma \in \Omega} \{D_\Psi(\sigma, \rho) \in \Omega,$$  \hspace{1cm} (118)

and it is equal to a unique projection $\rho_\mathcal{Q}$ of $\rho$ onto $\mathcal{Q}$ along a $\nabla$-geodesic that is $(g, \nabla, \nabla^\top)$-orthogonal at $\mathcal{Q}$ [7, 9]. More precisely, the projection $\rho_\mathcal{Q}$ is defined as such element of $\mathcal{Q}$ that

$$g_{\rho_\mathcal{Q}}(c^\nabla(t), c^\nabla^\top(s)) = 0 \ \forall c^\nabla^\top,$$  \hspace{1cm} (119)

where $c^\nabla(t)$ is a $\nabla$-geodesic connecting $\rho$ and $\rho_\mathcal{Q}$, while $c^\nabla^\top$ varies over all $\nabla^\top$-geodesics intersecting $\rho_\mathcal{Q}$ and entirely included in $\mathcal{Q}$.  

32
Hence, for dually flat geometries, projections onto $\nabla^1$-affine $\nabla^1$-convex sets along $\nabla$-geodesics coincide with the entropic projections of the associated Brègman relative entropies. In consequence, one can consider a local $\nabla$-geodesic flow to be an infinitesimal version of information dynamics defined by constrained relative entropy minimisation.

### 2.4.2 Quantum information geometries

Given a standard representation $(\mathcal{H}, \pi, J, \mathcal{H}^\natural)$ of a W*-algebra $\mathcal{N}$, consider a family of distances $D_f : \mathcal{N}^+_* \times \mathcal{N}^+_* \rightarrow [0, \infty]$ defined by

$$D_f(\omega, \phi) := \langle \xi_\pi(\phi), f(\Delta_{\omega, \phi})\xi_\pi(\phi) \rangle_{\mathcal{H}}$$  \hspace{1cm} (120)

if $\text{supp}(\omega) \leq \text{supp}(\phi)$ and $D_f(\omega, \phi) := +\infty$ otherwise, where $f : \mathbb{R}^+ \rightarrow \mathbb{R}$ is any operator convex function (i.e. $f(tx + (1-t)y) \leq tf(x) + (1-t)f(y) \forall x, y \in \mathcal{N}^+ \forall t \in [0, 1]$) satisfying $f(0) \leq 0$ and $f(1) = 0$. As proved in [270, 349], all $D_f$ satisfy the condition

$$D(\omega, \phi) \geq D(T^\gamma(\omega), T^\gamma(\phi)) \forall \omega, \phi \in \mathcal{M}(\mathcal{N}) \ \forall T^\gamma : \mathcal{N}^+_* \rightarrow \mathcal{N}^+_*,$$  \hspace{1cm} (121)

where $T^\gamma$ denotes a Banach predualisation of a weakly-* continuous unital completely positive map $T : \mathcal{N} \rightarrow \mathcal{N}$, and $\mathcal{M}(\mathcal{N}) \subseteq \mathcal{N}^+_*$ is arbitrary. Moreover, the equality is attained iff $T^\gamma$ is an isomorphism [143].

For

$$f_\gamma(t) := \begin{cases} \frac{1}{\gamma} + \frac{1}{1-\gamma} t - \frac{1}{(1-\gamma) t^\gamma} & : \gamma \in \mathbb{R}\backslash\{0, 1\} \\ t \log t - (t - 1) & : \gamma = 1 \\ -\log t + (t - 1) & : \gamma = 0, \end{cases}$$  \hspace{1cm} (122)

the restriction to $\gamma = 1$ and $\mathcal{M}(\mathcal{N}) \subseteq \mathcal{N}^+_*$ gives [19, 20]

$$D_1|_{\mathcal{N}^+_*} (\omega, \phi) = \langle \xi_\pi(\phi), \log(\Delta_{\omega, \phi})\xi_\pi(\phi) \rangle_{\mathcal{H}}$$  \hspace{1cm} (123)

which, for $\mathcal{N} \cong \mathfrak{B}(\mathcal{H})$, turns to [352, 353]

$$D_1|_{\mathfrak{B}(\mathcal{H})} (\omega, \phi) = \text{tr}_\mathcal{H}(\rho_\omega \log(\rho_\omega) - \rho_\omega \log(\rho_\omega)).$$  \hspace{1cm} (124)

Jenčová [184, 185] proposed to consider a (Young) function

$$\Upsilon_\phi : \mathcal{N}^{sa} \ni h \rightarrow \frac{1}{2}(\phi^h(\|) + \phi^{-h}(\|)) - 1 \in \mathbb{R}^+,$$  \hspace{1cm} (125)
where $\mathcal{N}$ is an arbitrary W*-algebra, and
\[
\tilde{\phi}^h(\|) := \sup_{\omega \in \mathcal{N}^+} \{-D_1|_{\mathcal{N}^+} (\omega, \phi) + \omega(h) + \omega(\|)\} \tag{126}
\]
With this function, she defined a noncommutative Orlicz space $L_{\mathcal{T}_\phi}(\mathcal{N})$ as a completion of $\{x \in \mathcal{N}^+ \mid \exists \lambda > 0 \quad \mathcal{T}_\phi(\lambda x) < \infty\}$ in the norm $\|x\|_{\mathcal{T}_\phi} := \inf\{\lambda > 0 \mid \mathcal{T}_\phi(\lambda^{-1} x) \leq 1\}$. This space satisfies
\[
\mathcal{N}^+ \subseteq L_{\mathcal{T}_\phi}(\mathcal{N}) := \overline{\mathcal{N}^+}_{\|_{\mathcal{T}_\phi}}. \tag{127}
\]
Given the choice of a Hilbert space $\mathcal{H}$ with $\dim \mathcal{H} = n < \infty$ and a smooth bijective parametrisation $\Theta : \mathbb{R}^m \to \mathbb{R}^m$, $m \in \mathbb{N}$, the parametric quantum manifold is defined as a quantum model
\[
\mathcal{M}(\mathcal{H}) = \{\rho(\theta) \in \mathfrak{S}(\mathcal{H})^+_0 \mid \theta \in \Theta \subseteq \mathbb{R}^m\} \subseteq \mathfrak{S}(\mathbb{C}^n)^+_0 \cong M_n(\mathbb{C})_0^+. \tag{128}
\]
Usually, the additional condition $\text{tr}_\mathcal{H}(\rho(\theta)) = 1$ is imposed on the elements of $\mathcal{M}(\mathcal{H})$. A tangent space $\mathcal{T}_\phi M_n(\mathbb{C})_0^+$ is the real vector space of all Fréchet derivatives in the directions of smooth curves in $M_n(\mathbb{C})_0^+$ that pass through $\rho$, so it can be identified with a restriction of $M_n(\mathbb{C})^a$. A restriction of $\rho$ to $M_n(\mathbb{C})_0^+$ implies a restriction of the tangent vectors to the space $\{x \in M_n(\mathbb{C})^a \mid \text{tr}_\mathcal{C}(x) = 0\}$. A Banach smooth manifold structure on $\mathcal{N}^+_0$ for an arbitrary countably finite W*-algebra $\mathcal{N}$ was introduced by Jenčová [184, 185]. She proved that the quantum model $\mathcal{N}^+_0$ can be equipped with the smooth Banach manifold structure modeled on a family of Banach spaces
\[
L_{\mathcal{T}_\phi}^0(\mathcal{N}) := \{x \in L_{\mathcal{T}_\phi}(\mathcal{N}) \mid \phi(x) = 0\} = \{x \in \mathcal{N}^+ \mid \phi(x) = 0\} \|_{\mathcal{T}_\phi}. \tag{129}
\]
This structure is introduced by means of the smooth atlas $\{(w^{-1}_\phi(U(\phi)), \phi) \mid \phi \in \mathcal{N}^+_0\}$, where $U(\phi) := \{x \in L_{\mathcal{T}_\phi}^0(\mathcal{N}) \mid \|x\|_{\mathcal{T}_\phi} < 1\}$ and
\[
w^{-1}_\phi : L_{\mathcal{T}_\phi}^0(\mathcal{N}) \cong U(\phi) \ni h \mapsto \phi^h \in \mathcal{N}^+_0 \tag{130}
\]
is a diffeomorphism. If $\mathcal{N} \cong L_X(\mathcal{Y}, \mathcal{U}(\mathcal{X}), \tilde{\mu})$, then this construction reduces to a smooth Banach manifold structure on $L_1(\mathcal{X}, \mathcal{U}(\mathcal{X}), \tilde{\mu})^+_0$, introduced in [274, 122]. We conjecture that (analogously to the extension of this smooth manifold structure from $L_1(\mathcal{X}, \mathcal{U}(\mathcal{X}), \tilde{\mu})^+_0$ to $L_1(\mathcal{X}, \mathcal{U}(\mathcal{X}), \tilde{\mu})^+_0$, provided in [22]) Jenčová’s construction can be extended to $\mathcal{N}^+_0$. Under this conjecture, we define a nonparametric quantum manifold as a quantum model $\mathcal{M}(\mathcal{N}) \subseteq \mathcal{N}^+_0$ equipped with a Banach smooth manifold structure induced from $\mathcal{N}^+_0$, by replacing $L_{\mathcal{T}_\phi}^0(\mathcal{N})$ with $L_{\mathcal{T}_\phi}(\mathcal{N})$.

Given any countably finite W*-algebra $\mathcal{N}$, a finite dimensional quantum model $\mathcal{M}(\mathcal{N}) \subseteq \mathcal{N}^+_0$ that is a Banach smooth submanifold of $\mathcal{N}^+_0$, and a quantum distance $D$ on $\mathcal{M}(\mathcal{N})$ that is smooth and satisfies (104), one can derive the corresponding quantum Norden–Sen geometry $(\mathcal{M}(\mathcal{N}), \mathbf{g}^D, \nabla^D, \nabla^D)$). In particular, given any distance $D_\|$, for $\mathcal{N} = \mathfrak{B}(\mathcal{H})$ and $\mathcal{M}(\mathcal{H}) = \mathfrak{S}(\mathcal{H})^+_0$, the corresponding riemannian metric $\mathbf{g}^{D_\|}$ takes the form [243, 271, 227]
\[
\mathbf{g}^{D_\|}(u, v) = \left< u, (\mathfrak{h}_f(\mathbf{L}_\|^{-1})^{-1} \mathbf{R}_\|^{-1})(v) \right> \mathfrak{S}_2(\mathfrak{H}), \tag{131}
\]
where $u, v \in \{x \in \mathfrak{B}(\mathcal{H}) \mid \text{tr}_\mathcal{H}(x) = 0\}$, while $\mathfrak{h}_f : [0, \infty[ \to [0, \infty]$ is an operator monotone increasing function defined by
\[
\mathfrak{h}_f(\lambda) := \frac{(\lambda - 1)^2}{f(\lambda) - \lambda f(\frac{1}{\lambda})}. \tag{132}
\]

24More precisely, it is a noncommutative analogue of a Morse–Transue–Krasnosel’skiĭ–Rutickii space, see [210] for details.

25The W*-algebras $\mathcal{N}$ which are not countably finite do not allow faithful quantum states: $\mathcal{N}^+_0 = \emptyset$.

26A closely related approach to construction of smooth information manifold, utilising Orlicz spaces of unbounded operators/functions instead of the MTKR spaces of bounded elements, was developed in [275] for $L_1(\mathcal{X}, \mathcal{U}(\mathcal{X}), \tilde{\mu})^+_0$ and in [337, 339, 340, 341, 342] for (a subspace of) $\mathfrak{S}(\mathcal{H})^+_0$.

27A function $\mathfrak{h} : \mathbb{R}^+ \to \mathbb{R}$ is called operator monotone increasing iff $0 \leq x \leq y \Rightarrow \mathfrak{h}(x) \leq \mathfrak{h}(y)$ $\forall x, y \in \mathfrak{B}(\mathcal{H})$ [231].
This implies that several different \( f \) lead to the same \( \mathfrak{h}_f \). Hence, for any riemannian metric given by (131) there is a family of distances \( D_f \) that have it as its second order Taylor term.

Using an integral representation

\[
f(\lambda) = c_1 (\lambda - 1) + c_2 (\lambda - 1)^2 + c_3 \frac{(\lambda - 1)^2}{\lambda} + \int_0^\infty \frac{\bar{\mu}(t)}{\lambda + t} dt,
\]

where \( c_2, c_3 \geq 0, c_1 \in \mathbb{R} \), and \( \bar{\mu} : [0, \infty] \to \mathbb{R}^+ \) is a measure satisfying \( \int_0^\infty \bar{\mu}(t) dt \in \mathbb{R} \) [227]. Jenčová [182] showed that the \( f \)-connections, defined by the Eguchi equation (106) applied to \( D_f \) distance, have the form

\[
g^{D_f}_p(\nabla^{D_f}_x y, z) = 2 \int_0^\infty \bar{\mu}(\lambda) \text{re} \left( \tilde{C}(\lambda, z, x, y) \right) - 2 \int_0^\infty \bar{\mu}(\lambda^{-1}) \left( \text{re} \left( \tilde{C}(\lambda, y, x, z) \right) + \text{re} \left( \tilde{C}(\lambda, y, x, z) \right) \right),
\]

where

\[
\tilde{C}(\lambda, x, y, z) := (1 + \lambda) \text{tr} \left( x \frac{1}{\lambda \mathfrak{R}_p + \mathfrak{S}_p(y)} + \frac{1}{\lambda \mathfrak{R}_p + \lambda \mathfrak{S}_p(z)} \right).
\]

The connections \( \nabla^{D_f} \) are torsion-free. Moreover, the family of quantum Norden–Sen smooth geometries \( (M_n(\mathbb{C}))^+, g^{D_f}, \nabla^{D_f}, (\nabla^{D_f})^\dagger \) for \( \gamma \in [-1/2, 1] \) is characterised as the dually flat Eguchi geometry arising from the \( D_f \) distances [181, 182]. This result corresponds to the class \( D_{\Psi} \) of quantum distances determined by (122) belonging to both families: \( D_{\Psi} \) and \( D_f \) [183, 210]. The relationships between various information geometric objects on quantum state spaces \( \mathcal{M}(\mathcal{N}) \) can be summarised in the following diagram:

![Diagram showing relationships between different quantum geometries.](image)

Picture 2. Relationships between different quantum geometries. \( E \) denotes an application of the Eguchi equations. \( \psi_\Psi \) denotes the construction of an associated canonical Brègman distance.

### 2.4.3 Orlicz spaces and Brègman projections

As a consequence of the above results, if \( \mathcal{M}(\mathcal{N}) \) is a dually flat manifold with respect to the triple \( (g^{D_f}, \nabla^{D_f}, (\nabla^{D_f})^\dagger) \), then \( D_f \)-entropic projections onto \( (\nabla^{D_f})^\dagger \)-affine-and-convex subsets are locally equivalent to \( \nabla^{D_f} \)-geodesic “free fall”. The construction of families of \( \nabla^{D_f} \)-connections in infinite
dimensional noncommutative case was provided in [113, 122, 338, 183, 184] using the linear structure of noncommutative $L_{1/\gamma}(\mathcal{N})$ and, in such case this statement also holds [183].

More generally (going a bit beyond the scope of the current paper), the quantum Bréguerman distance $D_\Psi$ is defined via nonlinear embeddings $(\ell_{L_\gamma(N)}(\phi), \ell_{(L_\gamma(N))^*}(\omega))$ into noncommutative Orlicz spaces $L_\gamma(N)$ and $(L_\gamma(N))^*$, respectively. These spaces play the role of a tangent space ‘of states’ and the cotangent space ‘of effects’, respectively (and similarly to the commutative case of [115, 113]). The $\nabla D_\Psi^{\dagger}$-affinity and $\nabla D_\Psi^{\dagger}$-convexity are defined as linear affinity and linear convexity in the Orlicz space $(L_\gamma(N))^*$ of effects. Thus, the global flatness of the connection on $L_\gamma(N)$ understood as a tangent space $T_{\phi}\mathcal{M}(N)$ corresponds to its parallel transport being given by a family of isomorphisms $U_{\phi,\omega}: T_{\phi}\mathcal{M}(N) \to T_{\phi}\mathcal{M}(N)$ satisfying $U_{\phi,\omega} = \text{id}|_{T_{\phi,0}\mathcal{M}(N)}$ and $U_{\phi,\omega} U_{\phi,\psi} = U_{\phi,\psi}$ [183]. From this point of view, the standard unitary transitions $V_{\phi,\omega}: \mathcal{H}_\omega \to \mathcal{H}_\phi$ can be understood as parallel transports of the connection defined naturally by the linear structure of the fibers in the GNS Hilbert bundle. This allows us to understand $V_{\phi,\omega}$ as a “free fall” along the geodesics of the Levi-Civita connection of $g^\gamma$ for $\gamma = \frac{1}{2}$, known as the Wigner–Yanase metric [377]. The riemannian distance of $g^{1/2}$ for $\mathcal{N} \cong \mathfrak{B}(\mathcal{H})$ reads [114]

$$d_{g^{1/2}}(\rho_1, \rho_2) = 2 \arccos \left( \text{tr}_\mathcal{H}(\sqrt{\rho_1} \sqrt{\rho_2}) \right).$$

(136)

On the boundary of pure spaces $g^{1/2}$ reduces to the Fubini–Study metric $g^{FS}$ (269) multiplied by the scalar factor 4 [272], hence (136) divided by 2 reduces to (271). A generalisation of $g^{1/2}$ to countably additive $W^*$-algebras was provided by Connes and Størmer [74]. For a given standard representation $(\mathcal{H}, \pi, J, \mathcal{H})$, it reads

$$g^{1/2}_{\phi}(x, y) = 2 \left\langle \left( J \pi(x^*) J - \pi(y) \right) \zeta_\pi(\phi) \right\rangle_\mathcal{H}.$$  (137)

For any $\mathcal{M}(N) \subseteq \mathcal{N}^+_0$, the GNS construction equipped with the Tomita–Takesaki theory defines a corresponding standard representation $(\mathcal{H}_\phi^\dagger, \pi_\phi, J_\phi, \mathcal{H}_\phi^\dagger)$. In such case, a direct calculation based on the properties (78)-(80), using $V_{\phi,\omega}$ in the role of $t_{\phi,\omega}^{\dagger}$ applied with respect to (137), shows that these objects satisfy the Levi-Civita version of the equation (103). The corresponding relative entropy is [183]

$$D_{1/2}(\phi, \psi) = 2 \left\| u_\phi \zeta_\pi(\phi) - u_\psi \zeta_\pi(\psi) \right\|^2_\mathcal{H},$$

(138)

where $u_\phi$ and $u_\psi$ are unique unitary operators arising from the polar decomposition of relative modular operators $\Delta_{\phi,\omega}$ and $\Delta_{\psi,\omega}$, respectively, where $\omega \in \mathcal{N}^+_0$ is arbitrary. When expressed as a Bréguerman distance on the standard representation Hilbert space $\mathcal{H}$, this relative entropy takes the form

$$D_{1/2}(x, y) = \frac{1}{2} \left\| x - y \right\|^2_\mathcal{H}$$

[183]. Hence, the local (infinitesimal) action of the operators $V_{\phi,\omega}$ can be understood as a geodesic free fall that is locally equivalent to the minimisation of the Hilbert space norm, which in turn corresponds to a continuous linear projection operator onto a convex closed subset. In what follows, we will use the GNS Hilbert bundle having in mind the above observations.

In face of presence of other approaches to construction of smooth manifold structure on the space $L_1(\mathcal{X}, \mathcal{U}(\mathcal{X}), \mu^0_{\Omega})$ [48, 22, 248], one may ask for the specific motivation of the Orlicz space based approach. The main reason is to guarantee that the local neighbourhoods of an information state (which are identified with the tangent space) are accessible by means of entropic projection. More precisely, each tangent vector is identified as an equivalence class of one dimensional exponential models (i.e., $p \exp(\lambda f - \log Z(p, \lambda f))$ in the neighbourhood of $p \in L_1(\mathcal{X}, \mathcal{U}(\mathcal{X}), \mu^0_{\Omega})$ and $\phi^\lambda h$ in the neighbourhood of $\phi \in \mathcal{N}^0_{\Omega}$). This can be viewed as a localised version of Jaynes’ maximum entropy principle [166, 172] (cf. [343]) of model construction. We consider it as a step that is conceptually similar to localisation of Minkowski space in the passage from special to general relativity theory: instead of working with information models that are globally exponential, we assume only that they are locally (infinitesimally) exponential. This leads to a question whether one can postulate local approximation by means of some other models (corresponding to minimisation of some different information distance functional), and construct smooth information manifold structure out of this postulate. In the commutative case this question has been answered in the affirmative by the recent work [357, 356, 358], who have generalised the construction of [275] to a large family of Orlicz (more precisely, Musielak–Orlicz) spaces. The Young functions that define these spaces define the corresponding Bréguerman distances. We conjecture
that the similar construction can be carried out in the noncommutative case. In the case when the information distance used for the construction of the smooth information manifold belongs to the Bréchman class, the resulting information manifold is no longer locally exponential, but it is locally dually flat (locally hessian). Because dually flat manifolds can be thought of as a generalisation of cartesian space, this construction strengthens analogy to relationship between Minkowski space-time and general lorentzian manifold. From the perspective of applications of entropic projections, one can say that the generalisation of Jenčová’s construction of a manifold structure from one based on $D_1$ to one based on Brèchman distances $D_\Psi$ would allow for local representations of entropic $D$-projections in terms of projections along $\nabla^{D_\ast}$-geodesics. If entropic projections are regarded as a form of information dynamics, then one can say that such construction of the smooth information manifold facilitates the possibility of introducing local (infinitesimal) representation of entropic information dynamics. Turning it to a slogan: introducing the structure of quantum information manifold based on a Young function $\Psi$ and a corresponding Brèchman distance $D_\Psi$ amounts to postulating that information flows locally along $\nabla^{D_\ast}$-geodesics.

In principle, one can construct smooth information manifold structure of $M(\mathcal{N})$ using some distance $D$, and then consider the geometric structures and information dynamics on $M(\mathcal{N})$ using some other distance $\tilde{D}$, or even using some class of distances, $\{D^i \mid i \in I\}$. However, using the same distance on both levels allows for stronger optimality results (concerning, for example, asymptotic estimation). More specifically, the same asymptotic results (up to third order) will be obtained for any $\tilde{D}$ that locally generates a dually flat geometry that agrees with a dually flat geometry of a Brèchman distance $D_\Psi$. Hence, the above slogan can be equipped with a user’s notice: a local Norden–Sen geometry and information dynamics of such manifold can be described by an arbitrary distance $D$ that has the same Taylor expansion, up to third order, as $D_\Psi$. Given an arbitrary quantum model $M(\mathcal{N})$ and a distance $D$ on $M(\mathcal{N})$, the pair $(M(\mathcal{N}), D)$ can be called dually flat localisable quantum geometry iff $M(\mathcal{N})$ can be equipped with a smooth manifold structure based on some Brèchman distance $D_\Psi$ that agrees with $D$ up to third order. Such quantum geometry can be considered as a proper information geometric analogue of a lorentzian manifold: while global geometry (and dynamics) of $M(\mathcal{N})$ is described in terms of $D$, locally it is equivalent with the description in terms of $D_\Psi$, which is equivalent with the description in terms of a dually flat geometry. See Section 5.3 for an application of these considerations for the problem of geometric nonperturbative renormalisation in quantum nonequilibrium statistical mechanics.

Let $W^\ast$-algebra $\mathcal{N}$ admit a trace $\tau \in W_0(\mathcal{N})$. A closed densely defined linear operator $x : \text{dom}(x) \to \mathcal{H}$ is called $\tau$-measurable [312, 247] iff

$$\exists \lambda > 0 \; \tau(p^{\lambda x}(|\lambda|, +\infty)) < \infty. \quad (139)$$

Let $\mathcal{M}(\mathcal{N}, \tau)$ denote the space of all $\tau$-measurable operators affiliated with $\pi_\tau(\mathcal{N})$. Let $\Upsilon : [0, \infty[ \to [0, \infty]$ be an Orlicz function, i.e. convex, continuous, nondecreasing, $\Upsilon(0) = 0$, $\lambda > 0 \Rightarrow \Upsilon(\lambda) > 0$, and $\lim_{\lambda \to -\infty} \Upsilon(0) = +\infty$. A noncommutative Orlicz space over $\mathcal{N}$ associated with $\Upsilon$ is defined as [220]

$$L_\Upsilon(\mathcal{N}, \tau) := \text{span}_C \{ x \in \mathcal{M}(\mathcal{N}, \tau) \mid \tau(\Upsilon(|x|)) \leq 1 \}, \quad (140)$$
equipped with a norm

$$\|x\| : \mathcal{M}(\mathcal{N}, \tau) \ni x \mapsto \inf \{ \lambda > 0 \mid \tau(\Upsilon(\lambda^{-1}|x|)) \leq 1 \} \quad (141)$$

which turn it into a Banach space. It follows that

$$L_\Upsilon(\mathcal{N}, \tau) = \{ x \in \mathcal{M}(\mathcal{N}, \tau) \mid \exists \lambda > 0 \; \tau(\Upsilon(\lambda|x|)) < \infty \}. \quad (142)$$

An issue of canonical generalisation of the notion of a noncommutative Orlicz space to an arbitrary $W^\ast$-algebra is a matter of a current research, see [212] for a discussion.

The construction of a general notion of a quantum Brèchman distance for arbitrary spaces $\mathcal{N}^+_\ast$ is an open problem. Let $X$ be a reflexive Banach space, let $\Psi : X \to [-\infty, +\infty]$ be convex, lower semi-continuous, and Legendre (see [26] for a definition). Let $C \subseteq X$ be nonempty and convex,
$C \cap \text{int}(\text{efd}(\Psi)) \neq \emptyset$, where $\text{efd}(\Psi) := \{ x \in X \mid \Psi(x) \neq +\infty \}$, and let $y \in \text{int}(\text{efd}(\Psi))$. Then the Brègman functional on $X$, defined by
\[ \tilde{D}_\Psi(x, y) := \Psi(x) - \Psi(y) - \left[ x - y, \mathcal{D}_y^G \Psi(y) \right]_{X \times X^*}, \tag{143} \]
for $y \in \text{int}(\text{efd}(\Psi))$, and $\tilde{D}_\Psi(x, y) = +\infty$ otherwise, satisfies [26]:
1) $\tilde{D}_\Psi(\cdot, y)$ is convex and lower semi-continuous,
2) $\text{efd}(\tilde{D}_\Psi(\cdot, y)) = \text{efd}(\Psi)$,
3) $\tilde{D}_\Psi(x, y) = 0 \iff x = y$,
4) $\mathcal{U}_C^\Psi(y) = \{ * \} \in \text{int}(\text{efd}(\Psi))$,
5) $\mathcal{U}_C^\Psi \circ \mathcal{U}_C^\Psi(y) = \mathcal{U}_C^\Psi(y)$,
6) if $K$ is a vector subspace of $X$, then Chencov’s generalised pythagorean theorem [57, 59] holds:
\[ \tilde{D}_\Psi(x, y) = \tilde{D}_\Psi(x, \mathcal{U}_K^\Psi(y)) + \tilde{D}_\Psi(\mathcal{U}_K^\Psi(y), y) \quad \forall (x, y) \in K \times X. \tag{144} \]

Let $X \cong L_\gamma(N)$, and consider a map $\ell_{L_\gamma(N)}: N_+ \rightarrow L_\gamma(N)$ satisfying $\ell_{L_\gamma(N)}(N_+^\ast) \subseteq (L_\gamma(N))^\ast$, $\ell_{L_\gamma(N)}(N_+) \subseteq \text{int}(\text{efd}(\Psi))$, and bijective on its codomain. Then the quantum Brègman distance is defined as [213]
\[ D_\Psi(\phi, \psi) := \tilde{D}_\Psi(\ell_{L_\gamma(N)}(\phi), \ell_{L_\gamma(N)}(\psi)) \quad \forall (\phi, \psi) \in N_+^\ast \times N_+^\ast. \tag{145} \]

The nontrivial open problem consists of finding the minimal additional conditions on $\Psi$ and $\ell_{L_\gamma(N)}$ that are necessary and sufficient to prove that $D_\Psi(\phi, \psi)$ is smooth (or at least triple Gâteaux differentiable) and satisfies the infinite dimensional analogue of the property (103) as well as an equivalence of $D_\Psi$-projections onto linear convex closed subspaces $\mathcal{Q}$ of $L_\gamma(N)$ with $(g^{D_\Psi}, \nabla^{D_\Psi}, (\nabla^{D_\Psi})^\dagger)$-orthogonal projections along $\nabla^{D_\Psi}$-geodesics onto $\mathcal{Q}$. These conditions will necessarily intertwine the properties of $\Psi$, $\gamma$, and $\ell_{L_\gamma(N)}$. See [213] for an additional discussion.

### 2.4.4 Conjecture: a Morozova–Chencov–Petz bundle

Let $(\mathcal{H}_\phi, \pi_\phi, \Omega_\phi)$ be a GNS representation of a $\mathcal{W}^*$-algebra $\mathcal{N}$ for $\phi \in N_+^\ast$. Consider a scalar product on $\mathcal{H}_\omega$, defined by
\[ \langle [x]_\phi, [y]_\phi \rangle_{h, \phi} := \langle [x^*]_\phi, \mathcal{J}_{h, \phi}([y]_\phi) \rangle_{\phi}, \tag{146} \]
\[ \mathcal{J}_{h, \phi} := \frac{1}{\hbar(\Delta_{h, \phi})} \mathcal{R}(\psi)^{-1}, \tag{147} \]

where $\mathcal{R}(\psi)$ is a right multiplication by $\psi \in N_+^\ast$ [318], while $\hbar: \mathbb{R}^+ \rightarrow \mathbb{R}^+$ is an operator monotone increasing function satisfying [271] $\hbar(\lambda) = \lambda \hbar(\lambda^{-1}) \ \forall \lambda > 0$ (all functions $\hbar$ given by (132) satisfy this property). We conjecture that:

1) the completion of the vector space $\pi_\phi(\mathcal{N})/\ker(J_{\phi}^h)$ in the scalar product (146) is a Hilbert space (denoted below as $\mathcal{H}_{h, \phi}$, with elements denoted by $[x]_{h, \phi}$ for any $x \in n_\phi$),
2) $\pi_{h, \phi}(x) : [y]_{h, \phi} \mapsto [xy]_{h, \phi}$ defines a nondegenerate faithful normal representation $\mathcal{N} \rightarrow \mathcal{B}(\mathcal{H}_{h, \phi})$,
3) a unique extension of the antilinear isometry $J_{h, \phi} : [x]_{h, \phi} \mapsto [x^*]_{h, \phi} \ \forall x \in n_\phi$ determines a conjugation on $\mathcal{H}_{h, \phi}$, turning a quadruple

\[
\left( \mathcal{H}_{h, \phi}, \pi_{h, \phi}, J_{h, \phi}, \bigcup_{x \in n_\phi} \{ \pi_{h, \phi}(x) J_{h, \phi} [x]_{h, \phi} \}^\mathcal{H}_{h, \phi} \right) \tag{148}
\]

to a standard representation.
If this conjecture holds, then the above construction determines a bundle of Hilbert spaces over any topological space $\mathcal{M}(\mathcal{N}) \subseteq \mathbb{N}_0^*$. We will refer to it as a Morozova–Chencov–Petz bundle (it could be defined equivalently using the Morozova–Chencov functions $c$ instead of Petz’s functions $\mathfrak{h}$, see e.g. [213]). Clearly, it provides an alternative to the GNS bundle. A virtue of the MCP bundle is that it encodes the local riemannian geometry of the state space in the variability of changes of the scalar product. Yet, it remains an open problem whether the above conjecture is true.

2.5 Local gauge and geodesic propagation

If $\mathfrak{g}$ is a Banach Lie algebra with a Lie bracket $[\cdot, \cdot]$, then a representation of $\mathfrak{g}$ on a dense subset $\mathcal{D} \subseteq \mathcal{H}$ of a Hilbert space $\mathcal{H}$ is defined as a linear function $a$ mapping each $x \in \mathfrak{g}$ to an anti-selfadjoint operator $a(x) : \mathcal{D} \to \mathcal{H}$ such that

$$a([x, y]) = a(x)a(y) - a(y)a(x) \quad \forall x, y \in \mathfrak{g}. \quad (149)$$

Hence, for a given representation $a$ of $\mathfrak{g}$ on $\mathcal{D} \subseteq \mathcal{H}$, every $x \in \mathfrak{g}$ determines a unique self-adjoint, and generally unbounded, operator $ia(x)$. By definition, $\mathcal{D} = \text{dom}(ia(x))$.

Let $G$ be a Lie group, and let $\mathcal{M}(\mathcal{N}) \subseteq \mathbb{N}_0^*$ be equipped with a principal $G$-bundle $E \to \mathcal{M}(\mathcal{N})$, and a $\mathfrak{g}$-valued connection one-form $A$ on $E$, where $\mathfrak{g}$ is a Lie algebra of $G$. Moreover, assume that the GNS bundle $\mathcal{H}\mathcal{M}(\mathcal{N})$ is equipped with the family $a$ of the representations of the Lie algebra $\mathfrak{g}$.\(^{28}\)

$$a := \{a_\omega : \mathfrak{g} \to (\text{Lin}(\mathcal{H}_\omega))^\text{asa} \mid \omega \in \mathcal{M}(\mathcal{N})\}. \quad (150)$$

The triple $(\mathcal{M}(\mathcal{N}), A, a)$ satisfying the above conditions will be called a local gauge model, while the pair $(A, a)$ will be called a local gauge structure on $\mathcal{M}(\mathcal{N})$.\(^{29}\) In principle, a given manifold $\mathcal{M}(\mathcal{N})$ can admit various different local gauge structures.

If the model $\mathcal{M}(\mathcal{N})$ is equipped with the local gauge structure, then any curve $c : \mathbb{R} \ni t \mapsto \phi(t) \in \mathcal{M}(\mathcal{N})$ corresponds also to a specific choice of a section of the principal $G$-bundle $E$ along this trajectory, which can be expressed by means of integral of a $\mathfrak{g}$-valued connection 1-form $A$.

If $a$ is determined by setting $i a_\omega(\mathfrak{g})$ to be equal to the generators of the irreducible unitary representation of an action of $G$ on $\mathcal{H}_\omega$, then one can apply Wigner’s theorem [376] to each fibre of $\mathcal{H}\mathcal{M}(\mathcal{N})$ separately, classifying the elements of $\mathcal{H}_\omega$ into subsets by means of their transformation properties. According to Wigner’s interpretation of this mathematical property (which became widely accepted afterwards), an element of $\mathcal{H}_\omega$ transforming under the above representation of $G$ shall be understood as a pure state of a ‘quantum particle’, where pure state means a vector in a Hilbert space.

Our framework allows to enrich this interpretation by considering a propagation of a ‘quantum particle’ state over the trajectory on the manifold $\mathcal{M}(\mathcal{N})$, using the $\mathfrak{g}$-valued connection one-form $A$. As discussed in Section 2.2, if $\mathcal{M}(\mathcal{N}) \subseteq \mathbb{N}_0^*$, then every two standard representations determine a unique standard unitary transition between them that preserves the standard cone. Hence, one can map uniquely between the elements of the fibres $\mathcal{H}_{\phi_1}$ and $\mathcal{H}_{\phi_2}$, whenever $\phi_1, \phi_2 \in \mathbb{N}_0^*$, by means of the standard unitary transition operator $V_{\phi_1, \phi_2}$. Let $\mathcal{M}(\mathcal{N}) \subseteq \mathbb{N}_0^*$, let $c : [0, t] \to \mathcal{M}(\mathcal{N})$ be a curve with $c(0) = \omega$ and $c(t) = \phi$, let $\xi \in \mathcal{H}_\omega$ and $\zeta \in \mathcal{H}_\phi$. Then $\zeta$ will be called an $A$-propagation of $\xi$ along $c$ iff $i a_\phi(\int_0^t A) - i a_\omega(\int_0^t A) J_\phi$ is essentially self-adjoint on $\text{dom}(i a_\phi(\int_0^t A)) \cap \text{dom}(i a_\omega(\int_0^t A) J_\phi)$ and

$$\zeta = U_{c, \omega}^A(t) V_{\phi, \omega} \xi := e^{-it(i a_\phi(\int_0^t A) + i J_\phi a_\phi(\int_0^t A) J_\phi)} V_{\phi, \omega} \xi = e^{it(i a_\phi(\int_0^t A) \cdot \cdot)} V_{\phi, \omega} \xi. \quad (151)$$

The operator $V_{\phi, \omega}$ is a parallel transport associated with the natural connection in the GNS Hilbert bundle determined by the linear structure of the Hilbert space. Hence, the equation (151) can be

\(^{28}\)This definition covers also the representations of $\mathfrak{g}$ in the well-adapted Banach–Lie subalgebras $\mathcal{B} \subseteq \epsilon^{-1}(\omega)$ (thus, within the fibers of $\mathcal{K}\mathcal{M}(\mathcal{N})$) as the special case.

\(^{29}\)The term gauge means the section of a principal $G$-bundle [369, 370]. The local gauge means the local section, while the global gauge means the global section. A particularly interesting example of a local gauge structure is provided by the choice of a locally compact and connected Lie group $G = \text{SO}^+(1, 3) \ltimes \mathbb{R}^4$, known as ortochronous Poincaré group.
understood as an updating map $\xi \mapsto \zeta$ along the trajectory $c(t)$ that takes into account both $A$ and $\nabla g^{1/2}$ connections.

The above construction suggests introducing more tight relationship between the connection structures of $T_M(\mathcal{N})$ and $\mathcal{H}M(\mathcal{N})$ for any local gauge model $(\mathcal{M}(\mathcal{N}), A, a)$ such that $\mathcal{M}(\mathcal{N})$ can be equipped with a smooth manifold structure, and with $\mathcal{M}(\mathcal{N}) \subseteq \mathcal{N}_0^\times$. Two quite intriguing possibilities are:

(QP$_1$) introduce an affine connection $\nabla$ on $T_M(\mathcal{N})$ and define gauge geodesic propagation as an $A$-propagation along $\nabla$-geodesic in $\mathcal{M}(\mathcal{N})$;

(QP$_2$) introduce: i) an action of $G$ on $T_M(\mathcal{N})$ turning it to a tangent $G$-bundle, ii) a $g$-valued connection 1-form $A^g_T$ on $T_M(\mathcal{N})$, and iii) a $g$-valued connection 1-form $A^g$ on $\mathcal{H}M(\mathcal{N})$, such that the $A^g_H$-parallel transports along $A^g_T$-geodesics in $\mathcal{M}(\mathcal{N})$ are equal to $U^A(t)V_{\phi,\omega}$ or $V_{\phi,\omega}U^A(t)$ (where $t$ is an affine parameter of an $A^g_T$-geodesic $c(t) \in \mathcal{M}(\mathcal{N})$), and define gauge geodesic propagation as a horizontal lift of an $A^g_T$-geodesic in $\mathcal{M}(\mathcal{N})$ with respect to $A^g_H$. These gauge geodesic propagations are precisely the $A$-propagations along $A^g_T$-geodesics in $\mathcal{M}(\mathcal{N})$. So, this what we gain by such definition is an additional structure on $\mathcal{H}M(\mathcal{N})$ that allows for further study of a relationship between $(G, g, A^g)$-structures of $T_M(\mathcal{N})$ and $\mathcal{H}M(\mathcal{N})$. On the other hand, the price paid is the requirement that the $A^g_H$-parallel transport along $A^g_T$-geodesic depends only on its endpoint, which holds if $\mathcal{M}(\mathcal{N})$ is simply connected and $A^g_H$ is flat.

If the definition (QP$_1$) is used, and $G$ and $a$ are chosen as for Wigner’s ‘quantum particle’ classification discussed above, then the gauge geodesic propagation has a direct interpretation as an $A$-propagation of a ‘quantum particle’ due to “free fall” along $\nabla$-geodesic. Note that (despite ‘dynamical’ feeling associated with the word ‘fall’) this propagation has no ‘dynamical’ (causal) content: it is an extension of the description of gauge transformation properties of a ‘quantum particle’ state from a single Hilbert space to a Hilbert space fibre bundle over a quantum model equipped with a local gauge structure. In such approach, a ‘quantum particle’ becomes identified with a (not necessarily global) section of a fibre $G$-bundle represented in terms of the fibre bundle of the GNS Hilbert spaces, so one can discuss its quantum propagation between some ‘source model’ and some ‘sink model’, defined as suitable submanifolds of $\mathcal{M}(\mathcal{N})$. Under the choice of a definition (QP$_1$), we will define a gauge geodesic propagation model as a local gauge model $(\mathcal{M}(\mathcal{N}), A, a)$ equipped with an affine connection $\nabla$.

The motivation and interpretation of these definitions echoes Einstein’s postulate [98, 97] of identification of geodesic lines with the “world-lines of freely moving point-particles”, but generalised from the pseudo-riemannian geometry, for which the geodesics of the Levi-Civita connection coincide with the curves of extreme distance of a pseudo-riemannian metric, to the setting of general affine connections [307] (see e.g. [294, 234] and references therein for a comparative discussion of these two approaches). The above construction of geodesic propagation of ‘quantum particles’ is partially influenced by the works of Drechsler [87, 88, 89] and Prugovečki [278, 279, 280, 281, 282, 283, 285, 284] (see also [123, 124]). As opposed to them, we do not require any pseudo-riemannian metric on the base manifold, so we do not introduce soldered Poincaré frame bundles, and we also consider the GNS Hilbert spaces (which may be unitarily inequivalent, if $\omega \not\in \mathcal{N}_0^\times$) varying over the base manifold instead of pasting fibre bundle from identical copies of a single Hilbert space. Moreover, our manifold is a space of quantum states over $\mathcal{W}^*$-algebras, as opposed to a priori postulated background space-time. On the other hand, similarly to Prugovečki (see [281, 283, 284]), and as opposed to the approaches of Wightman [371, 372, 373, 374] and Haag–Kastler [126, 128], we impose the requirement of Poincaré covariance not on the topological subsets of the base manifold and on the (presheaves of) algebras of operators associated (functorially [47]) to those subsets, but on the fibres of geometric fibre bundle and on the fibre bundle of Hilbert spaces over this manifold. (Note that, in addition, one can also introduce an independent group covariance requirement on the elements of an underlying $\mathcal{W}^*$-algebra, determining this way their transformation properties at each fibre by means of the GNS representation.)

If $\mathcal{M}(\mathcal{N})$ is equipped with the structure of quantum information manifold, and with a quantum information distance $D_t$, then (at least in the finite dimensional case) $\nabla$ can be chosen to be
the following statements are true: then for \( f \), if the Dereziński, Jakšić and Pillet in [80], and based on earlier results of Araki [17, 16]. According to

In this Section we will use the approach to unbounded ‘perturbations’ of liouvilleans, developed by

entropy.

fall” along the (local) information dynamics, determined by a constrained minimisation of a relative

\[ \nabla \text{entropic projection of the associated Brègman distance} \]

\[ \text{given by } \nabla \text{with } \nabla \text{entropic projection of the associated Brègman distance} \]

\[ \text{fall" along the (local) information dynamics, determined by a constrained minimisation of a relative} \]

3 Locally perturbed liouvilleans

In this Section we will use the approach to unbounded ‘perturbations’ of liouvilleans, developed by

the Dereziński, Jakšić and Pillet in [80], and based on earlier results of Araki [17, 16]. According to

1. \( \mathcal{C} \subseteq \mathcal{B}(\mathcal{H}) \) is a von Neumann algebra,

2. \( (\mathcal{C}, \mathbb{R}, \varsigma) \) is a \( \mathbb{W}^* \)-dynamical system with a standard liouvillean \( K^\varsigma \) associated with a standard

3. \( Q \) is a self-adjoint linear operator affiliated to \( \mathcal{C} \),

4. \( K^\varsigma + Q \) is an essentially self-adjoint linear operator on \( \text{dom}(K^\varsigma) \cap \text{dom}(Q) \subseteq \mathcal{H} \),

then for

\[ q^Q_t(x) := e^{it(K^\varsigma + Q)x}e^{-it(K^\varsigma + Q)} \quad \forall x \in \mathcal{C} \quad \forall t \in \mathbb{R} \]  

(152)

the following statements are true:

1. \( (\mathcal{C}, \mathbb{R}, \varsigma^Q) \) is a \( \mathbb{W}^* \)-dynamical system.

2. the operator

\[ E_{\varsigma,Q}(t) := e^{it(K^\varsigma + Q)}e^{-itK^\varsigma} \in \mathcal{C}, \]  

(153)

called an \textbf{expansional}, is unitary and for all \( t, t_1, t_2 \in \mathbb{R} \) and all \( x \in \mathcal{C} \) it satisfies the following cocycle conditions:

\[ q^Q_t(x) = E_{\varsigma,Q}(t)q_t(x)E_{\varsigma,Q}(t)^{-1}, \]  

(154)

\[ E_{\varsigma,Q}(t)^{-1} = E_{\varsigma,Q}(t)^* = \varsigma(E_{\varsigma,Q}(-t)), \]  

(155)

\[ E_{\varsigma,Q}(t_1 + t_2) = E_{\varsigma,Q}(t_1)q_t(E_{\varsigma,Q}(t_2)). \]  

(156)

3. if

\[ K^{\varsigma,Q} := K^\varsigma + Q - JQJ \]  

(157)

is an essentially self-adjoint linear operator on \( \text{dom}(K^\varsigma) \cap \text{dom}(Q) \cap \text{dom}(JQJ) \), then a unique self-adjoint extension of \( K^{\varsigma,Q} \), denoted (with an abuse of notation) by the same symbol, is a standard liouvillean of \( \varsigma^Q \) in \( (\mathcal{H}, \mathcal{C}, J, \mathcal{H}^\mathbb{C}) \). We will call \( K^{\varsigma,Q} \) and \( \varsigma^Q \) a \textit{Dereziński–Jakšić–Pillet perturbation} of \( K^\varsigma \) and \( \varsigma \), respectively.

4. if \( Q \) is bounded, then, for any \( x \in \mathcal{C} \) and \( t \in \mathbb{R} \), the Dyson–Feynman–Fujiwara–Araki perturbative expansions [92, 101, 105, 15],

\[ q^Q_t(x) = \sum_{n=0}^{\infty} i^n \int_{0 \leq t_n \leq \cdots \leq t_1 \leq t} dt_1 \cdots dt_n [s_{t_n}(Q), \ldots, [s_{t_1}(Q), s_t(x)] \ldots], \]  

(158)

\[ E_{\varsigma,Q}(t) = \sum_{n=0}^{\infty} i^n \int_{0 \leq t_n \leq \cdots \leq t_1 \leq t} dt_1 \cdots dt_n s_{t_n}(Q) \cdots s_{t_1}(Q). \]  

(159)
are convergent in weak-* topology and define a norm convergent series of bounded operators. Moreover, the associated generators $\overline{\partial}$ of $\zeta$ and $\overline{\partial}_Q$ of $\zeta^Q$ have in such case the same domain, and are related by

$$\overline{\partial}_Q(x) = \overline{\partial}(x) + i[Q, x] \quad \forall x \in \text{dom}(\overline{\partial}).$$

(160)

3.1 Local gauge liouvillians

In Section 2.3 we have observed that the Poisson flow of an algebraic hamiltonian vector field on $N^+_{0\omega}$ can be always represented by a unitary evolution in a fibre of the GNS bundle $\mathcal{H}N^+_{0\omega} \to N^+_{0\omega}$, generated by a standard liouvillean operator on this fibre. In what follows, we will abstract this relationship, replacing tangent bundle by a principal $G$-bundle and replacing the procedure of restriction of a global algebraic evolution, by the procedure of extension of a local algebraic evolution in order to incorporate geometric structure as an additional component of an effective dynamics.

If one assumes that the principal $G$-bundle structure participates in an effective form of a temporal evolution, then this evolution shall be represented not by the standard liouvillean on $\mathcal{H}_\phi(t)$ alone, but by the standard liouvillean perturbed by the ‘gauge connection’ operator $i\alpha_{(t)}(A)$, which represents the change of vectors in the fibres $\mathcal{H}_\phi(t)$ caused by the fibrewise action of the group $G$ and the choice of an $A$-section of a principal $G$-bundle $E$. (When the trajectory along the curve $c : [0, t] \to \mathcal{M}(N)$ with $c(0) = \phi(0)$ and $c(t) = \phi(t)$ is investigated as a source of memory effects, then $A$ should be replaced by $\int_0^t \alpha(t)$.)

For this purpose, we will use DJP perturbation approach, setting $\omega \in \mathcal{M}(N) \subseteq N^+_{0\omega}$, $G := \mathcal{H}_\omega$, $C := \pi_\omega(N)$, $Q := i\alpha_{(t)}(A)$. We can define $\zeta$ in different ways. If $N$ is equipped with a $W^*$ dynamical system structure $(N, R, \alpha)$, then one can define $\zeta$ globally in each fiber of the GNS bundle by means of

$$\zeta_\omega(\pi_\omega(x)) := \pi_\omega(\alpha_t(x)) \quad \forall x \in N \quad \forall t \in R \quad \forall \omega \in \mathcal{M}(N).$$

(161)

Alternatively, if $N$ is equipped with a quantum Poisson system $(\mathcal{M}(N, B), h)$ such that $\mathcal{D}^F_h \in N^+_{0\omega}$ $\forall \omega \in \mathcal{M}(N, B)$ and $\mathcal{M}(N, B) = \mathcal{M}(N)$, then one can define $\zeta$ pointwisely in each fiber by means of

$$\zeta_\omega(\pi_\omega(x)) := e^{it\pi_\omega(\mathcal{D}^F_h)}\pi_\omega(x)e^{-it\pi_\omega(\mathcal{D}^F_h)} \quad \forall x \in N \quad \forall t \in R \quad \forall \omega \in \mathcal{M}(N).$$

(162)

We will call these assumptions a generalised Poisson compatibility condition (PC2). If $B = N^+_{0\omega}$, $\mathcal{M}(N, N^+_{0\omega})$ is a submanifold of $N^+_{0\omega}$, and the pair $(h, \alpha)$ satisfies (97), then the above two definitions of $\zeta$ agree. The difference between (162) and (161) (the latter corresponding to the covariance equation (85)) indicates our approach to quantum dynamics, as being defined locally by the differential geometric properties of state space, instead of a global automorphism of an underlying algebraic structure.

Alternatively, if $\mathcal{M}(N) \subseteq N^+_{0\omega}$ is equipped with a quantum information manifold structure and a global vector field $\mathcal{X}_h \in T\mathcal{M}(N)$ such that $\mathcal{X}_h(\phi) \in N^+_{0\omega} \forall \phi \in \mathcal{M}(N)$, then $\zeta$ can be defined by

$$\zeta_\omega(\pi_\omega(x)) := e^{it\pi_\omega(\mathcal{X}_h(\omega))}\pi_\omega(x)e^{-it\pi_\omega(\mathcal{X}_h(\omega))} \quad \forall x \in N \quad \forall t \in R \quad \forall \omega \in \mathcal{M}(N).$$

(163)

Thus, under some relatively weak conditions (affiliation of $i\alpha_{(t)}(A)$ with $\pi_\omega(N) \subseteq \mathcal{B}(\mathcal{H}_\omega)$ and essential self-adjointness of sums $K_\omega^\omega + i\alpha_{(t)}(A)$ and $K_\omega^\omega + i\alpha_{(t)}(A) - iJ_\omega a_{(t)}(A)J_\omega$ on the intersection of domains of their components), the local gauge structure can be incorporated in the redefinition of the standard liouvillen. If

$$K_\omega^\omega \cdot i\alpha_{(t)}(A) = K_\omega^\omega + i\alpha_{(t)}(A) - iJ_\omega a_{(t)}(A)J_\omega$$

(164)

satisfies the above conditions, then we will call it a local gauge liouvillen at $\omega$.

Let $(\mathcal{M}(N), A, \alpha)$ be a local gauge model with $\mathcal{M}(N) \subseteq N^+_{0\omega}$ and let $\zeta$ be defined as above, either by a quantum Poisson system $(\mathcal{M}(N, B), h)$ with $\mathcal{D}^F_h \in N^+_{0\omega} \forall \omega \in \mathcal{M}(N, B)$ and $\mathcal{M}(N, B) = \mathcal{M}(N)$, or by a $W^*$-dynamical system $(N, R, \alpha)$ with $\alpha_{(t)}(\mathcal{M}(N)) \subseteq \mathcal{M}(N) \forall t \in R$. Let $\rho_\omega$ denote $w^\omega$ or $\alpha_\omega$, respectively. If for every $\omega \in \mathcal{M}(N)$ there exists a family of local gauge liouvillen

$$K_\omega^\omega + i\alpha_{(t)}(A) - iJ_\omega a_{(t)}(A)J_\omega,$$

(165)
a local gauge liouvillian model. From the above construction we see that the W*-dynamical system \((\pi_\omega(N), \mathbb{R}, \zeta^{\text{int}}(A))\) may not correspond to any W*-dynamical system on \(N\). The description of temporal evolution in terms of \(\zeta^{\text{int}}(A)\) is ‘local’ in the sense that it is provided inside of each fibre of the GNS bundle independently.

### 3.2 Local source liouvilleans

In principle, apart from the ‘internal’ dynamics (implemented by the evolution \(\zeta^\omega\)) and the kinematic local gauge structure, the effective dynamics can also depend on some controlled ‘external’ constraints. We will assume that these constraints can be specified in terms of external ‘sources’, which can generally be represented by the variations \(\delta(\phi(x))\) of expectation values. These variations can be decomposed into two parts: the variations \((\delta\phi)(x)\) of states, and the variations \(\phi(\delta x)\) of operators. The constraints on changes \(\delta\phi\) can be handled by restricting the form of the model \(\mathcal{M}(N)\) (for a geometric approach, see [241, 177, 100, 209]). On the other hand, note that \(\delta x\) can be in principle arbitrary, so it can also depend on \(\phi\), and it may not arise as an infinitesimal change generated by a global automorphism of \(N\) (thus, it cannot be described by the setting of derivations of C*-algebras). We will implement the perturbations \(\delta x\) of elements \(x\) of (a local GNS representation of) a W*-algebra \(N\) by means of state dependent perturbations of liouvilleans. In this sense, the constraints on changes of operators will be handled by local (state dependent) additional terms modifying liouvillian evolution.

For this purpose, apart from local gauge structure on \(\mathcal{M}(N) \subseteq N^*_+\), we introduce also local source term, defined as a fibrewise family of operators

\[
(\lambda, H) : \mathcal{M}(N) \ni \omega \mapsto \lambda(\omega) H(\omega) \in (\text{Lin}(\mathcal{H}_\omega))^{\text{sa}},
\]

with \(\lambda(\omega) \in \mathbb{R}\) called local source strength and \(H(\omega) \in (\text{Lin}(\mathcal{H}_\omega))^{\text{sa}}\) called local source operator. If \(\lambda(\omega)\) is independent of \(\omega\), then it will be called global source strength. The \((2n + 1)\)-tuple

\[
(\mathcal{M}(N), (\lambda_1, H_1), \ldots, (\lambda_n, H_n))
\]

will be called local source model iff \((\lambda_i, H_i)\) is a local source term for each \(i \in \{1, \ldots, n\}\). If (167) is a local source model, \(\mathcal{M}(N) \subseteq N^*_0\), \(\varsigma\) is defined as in Section 3.1, and for \(\omega \in \mathcal{M}(N)\) the DJP perturbation of \(K^\varsigma_\omega\) by \(\lambda_1(\omega) H_1(\omega) + \ldots + \lambda_n(\omega) H_n(\omega)\) exists, then a unique self-adjoint extension of an essentially self-adjoint operator

\[
K^\varsigma_\omega \lambda_1 H_1, \ldots, \lambda_n H_n = K^\varsigma_\omega + \lambda_1(\omega) H_1(\omega) + \ldots + \lambda_n(\omega) H_n(\omega) - J_\omega(\lambda_1(\omega) H_1(\omega) + \ldots + \lambda_n(\omega) H_n(\omega)) J_\omega
\]

will be called local source liouvillian at \(\omega\). If a local source liouvillian exists for each \(\omega \in \mathcal{M}(N)\), then the \(2(n + 1)\)-tuple \((\mathcal{M}(N), \varsigma, \lambda_1, H_1, \ldots, \lambda_n, H_n)\) will be called local source liouvillian model. Let us note that a local source \(\lambda_i(\omega) H_i(\omega)\) at \(\omega\) should be understood not as the \(i\)-th type “interaction source” localised at \(\omega\), but as a strength-and-action of the \(i\)-th type “interaction source” perceived at location \(\omega\).

Let \((\mathcal{M}(N), A, a)\) be local gauge model. Let \((\mathcal{M}(N), \lambda_1, H_1, \ldots, \lambda_n, H_n)\) be local source model. Let \(\varsigma\) be such as defined in Section 3.1. If, for a given \(t \in \mathbb{R}\) and \(\omega \in \mathcal{M}(N)\), there exists a DJP perturbation of a standard liouvillian \(K^\varsigma_\omega\), given by the unique self-adjoint extension of an essentially self-adjoint operator

\[
\mathcal{L}(\omega, t) := K^\varsigma_\omega + ia_\omega(A) - iJ_\omega a_\omega(A) J_\omega + \sum_{i=1}^{n} (\lambda_i(\omega) H_i(\omega) - J_\omega \lambda_i(\omega) H_i(\omega) J_\omega),
\]

then \(\mathcal{L}(\omega, t)\) will be called a local liouvillian operator at \((\omega, t)\). If \(\mathcal{L}(\omega, t)\) exists for all \(t \in \mathbb{R}\) and all \(\omega \in \mathcal{M}(N)\), then the \((4 + 2n)\)-tuple

\[
(\mathcal{M}(N), \varsigma, A, a, \lambda_1, H_1, \ldots, \lambda_n, H_n)
\]

will be called an local liouvillian model. In the special case, all of operators \(H_1, \ldots, H_n\) can be determined by the elements \(h_1, \ldots, h_n\) of a W*-algebra \(N\), with

\[
H_i(h_i) : \mathcal{M}(N) \ni \omega \mapsto H_i(\omega) := \pi_\omega(h_i) \in \mathcal{B}(\mathcal{H})^{\text{sa}}.
\]

43
This allows, in particular, for a fibrewise representation of a ‘global gauge’ action $G_0 \rightarrow \text{Aut}(\mathcal{N})$ of some Lie group $G_0$ (not necessarily related to $G$), whenever $\{h_i\} \subseteq \mathcal{N}$ are the generators of the representation of $G_0$ in $\text{Aut}(\mathcal{N})$. This observation can be generalised to $l$ subsets of $\{h_1, \ldots, h_n\}$ playing the role of generators of $l$ representations of $l$ Lie groups $G_l \rightarrow \text{Aut}(\mathcal{N})$.

3.3 Case study: The BLP perspective on nonlinear quantum fields

Restriction of considerations from topological spaces $\mathcal{M}(\mathcal{N})$ to BLP manifolds $\mathcal{M}(\mathcal{N}, \mathcal{B})$ allows us to equip the operator algebraic approach with an additional differential geometric content, using Fréchet derivatives of smooth functions on $\mathcal{B}$, in the role of differential forms. In this Section we will investigate the possibility of interpretation of these forms as nonlinear quantum fields (understood in quite formal sense).

If $f \in C^\infty_c(\mathcal{B}; \mathbb{R})$ and $\phi \in \mathcal{M}(\mathcal{N}, \mathcal{B})$, then $\mathcal{D}_\phi f = d_\phi f = df(\phi) \in \mathcal{T}_\phi^B \mathcal{M}(\mathcal{N}, \mathcal{B})$. Thus, if $\mathcal{M}(\mathcal{N}, \mathcal{B}) \subseteq \mathcal{N}^{\mathbb{R}_+}$, $f \in C^\infty_c(\mathcal{M}(\mathcal{N}, \mathcal{B}); \mathbb{R})$ satisfies $\mathcal{D}_\phi f \in \mathbb{N}^{\omega} \forall \omega \in \mathcal{M}(\mathcal{N}, \mathcal{B})$, and $\zeta$ is defined as in the previous two Sections, then one can consider local source liouvilleans determined by the perturbation

$$K_\omega + \lambda(\omega) \left( \pi(\omega, \mathcal{D}_\omega f) - J_\omega \pi(\omega, \mathcal{D}_\omega f) J_\omega \right),$$

(172)

for some family $\lambda(\omega) \in \mathbb{R} \forall \omega \in \mathcal{M}(\mathcal{N}, \mathcal{B})$. As opposed to a function used for definition of $K_\omega$, $f$ is not considered as a generator of a Poisson flow, and it is allowed to be arbitrary rescaled by $\lambda(\omega)$ at each point.

Every $x \in \mathcal{B}$ can be represented again as a smooth function on $\mathcal{B}$, by means of $\mathcal{B} \ni \omega \mapsto \omega(x) \in \mathbb{R}$, allowing to consider elements of $\mathcal{B}$ arising from multiple Fréchet differentiation,

$$\mathcal{D}_{\omega_n}(\phi_{n-1}(\mathcal{D}_{\omega_{n-1}}(\cdots (\phi_1(\mathcal{D}_1 f)))))) \in \mathcal{B},$$

(173)

for $\omega_1, \ldots, \omega_n, \phi_1, \ldots, \phi_{n-1} \in \mathcal{B}$. These derivatives can be added and multiplied as elements of $\mathcal{B}$, and any of the resulting elements of $\mathcal{B}$ can be subjected to a representation in the GNS bundle as a local source operator. However, despite multiple application of Fréchet differentiation, objects of type (173) are (just) elements of $\mathcal{T}_{\omega_n}^B \mathcal{B}$. This leads us to ask whether it is possible to introduce higher order tensors on $\mathcal{B}$, which could be used as source terms acting on the GNS bundle. The natural candidates for this purpose are $(n, m)$-tensor fields over $\mathcal{B}$, defined pointwisely as

$$\mathcal{X}_{k_1}(\phi) \cdots \mathcal{X}_{k_n}(\phi) \boxtimes df_1(\phi) \cdots df_m(\phi),$$

(174)

which are the elements of

$$\left( \mathcal{T}_\phi \mathcal{B} \right)^n \boxtimes \left( \mathcal{T}_\phi \mathcal{B} \right)^m \cong \left( \mathcal{T}_\phi \mathcal{B} \right)^{n \times m},$$

(175)

where $\boxtimes$ denotes the tensor product considered in an algebraic sense (that is, without taking topological completion) and the dependence on $\phi$ is assumed to be smooth. The contraction at $\phi$ of an $(n, m - 1)$-tensor field with an $(n, m)$-tensor field by means of the componentwise application of the duality $\left[ \left[ \cdots \left[ \mathcal{T}_\phi \mathcal{B} \right] \cdots \left[ \mathcal{T}_\phi \mathcal{B} \right] \right] \cdots \left[ \mathcal{T}_\phi \mathcal{B} \right] \right] \boxtimes \left( \mathcal{T}_\phi \mathcal{B} \right)^{n \times m}$ gives a one-form at $\phi$, which belongs to $\mathcal{B}$:

$$[d_1(\phi) \boxtimes \cdots \boxtimes d_{n-1}(\phi) \boxtimes \mathcal{X}_{k_1}(\phi) \boxtimes \cdots \boxtimes \mathcal{X}_{k_n}(\phi)] [d_1(\phi) \boxtimes \cdots \boxtimes d_{m-1}(\phi) \boxtimes df_1(\phi) \boxtimes \cdots \boxtimes df_m(\phi)] = [\mathcal{X}_{k_1}(\phi), d_1(\phi)] \cdots [\mathcal{X}_{k_n}(\phi), d_1(\phi)] [\mathcal{X}_{h_1}(\phi), df_1(\phi)] [\mathcal{X}_{h_1-1}(\phi), df_1-1(\phi)] \cdots [\mathcal{X}_{h_m}(\phi), df_m(\phi)] \cdot df_1(\phi) =: \lambda(\phi) df_1(\phi).$$

(176)

When subjected to representation as a source term, $\lambda(\phi)$ is a natural candidate for a local source strength of a local source operator $\pi(\mathcal{D}_1 f(\phi))$. We will (tentatively) call the local source operators of this type quantum fields. One can also introduce the antisymmetric wedge product on vectors and covectors (one forms) and define the corresponding contraction to 1-form and its source term representation in an analogous way. In particular, for $\mathcal{B} \cong \mathcal{N}^{sa}$, a vector field $\mathcal{X}_k \in \mathcal{T}_\mathcal{M}(\mathcal{N}, \mathcal{B})$ can be represented in terms of a GNS fibre bundle $\mathcal{H}_\mathcal{M}(\mathcal{N}, \mathcal{B})$ as a family

$$\mathcal{M}(\mathcal{N}, \mathcal{B}) \ni \phi \mapsto \omega_{\mathcal{X}_k}(\phi) \in \mathcal{B}(\mathcal{H}_\phi)^{sa} \cong \mathcal{B}(\mathcal{H}_\phi)^{sa}$$

(177)
determined by
\[
\| [X_k(\phi), df(\phi)] \|_{T_{\phi}\Lambda^\ast \times T_{\phi}\Lambda^\ast} = \| \omega X_k(\phi), \pi\phi(df(\phi)) \|_{\mathcal{B}(\mathcal{H}_\phi)\otimes\mathcal{B}(\mathcal{H}_\phi)} \quad \forall \phi \in \mathcal{M}(\mathcal{N}) \quad \forall f \in \mathbb{C}_F^\infty(\Lambda_{\phi}^n; \mathbb{R}).
\] (178)

The GNS representation of $(0, n)$-tensor fields with $n > 1$ is also possible, however it can be provided in different ways. For example, given a $(0, 2)$-tensor field $(df \otimes dk)(\phi)$, it is possible to represent it as:
\[
\begin{align*}
\pi_{\phi}(df(\phi)) & \otimes \pi_{\phi}(dk(\phi)) \in \mathcal{B}(\mathcal{H}_\phi) \otimes \mathcal{B}(\mathcal{H}_\phi), \\
\pi_{\phi}(df(\phi)) & \otimes \pi_{\phi}(dk(\phi)) \in \mathcal{B}(\mathcal{H}_\phi \otimes \mathcal{H}_\phi), \\
\pi_{\phi\otimes\phi}(df \otimes dk)(\phi) & \in \mathcal{B}(\mathcal{H}_{\phi\otimes\phi}),
\end{align*}
\] (179) (180) (181)

where $(\mathcal{H}_{\phi\otimes\phi}, \pi_{\phi\otimes\phi}, \Omega_{\phi\otimes\phi})$ is the GNS representation of $\mathcal{N} \otimes \mathcal{N}$ in the state $\phi \otimes \phi \in (\mathcal{N} \otimes \mathcal{N})^+$. It seems that the representation (181) preserves most precisely the geometric content of $(0, 2)$-tensor field, so we feel tempted to consider it as a preferred construction. However, this leads us to construction of a whole family of fibre bundles of Hilbert spaces over the manifold $\mathcal{M}(\mathcal{N}, \mathcal{B})$. It is unclear at this stage whether this phenomenon should be considered as a virtue or as a failure. For $n$-ary tensor product $\phi \otimes \cdots \otimes \phi$ the corresponding fibre bundle of $\mathcal{H}_{\phi\otimes\cdots\otimes\phi}$ spaces, with $\phi$ varying over $\mathcal{M}(\mathcal{N}, \mathcal{B})$, will be called a $\otimes^n$-GNS bundle, and denoted $(\otimes^n \mathcal{H})\mathcal{M}(\mathcal{N}, \mathcal{B})$. For any $(0, n)$-tensor field $df_1 \otimes \cdots \otimes df_n$ on $\mathcal{M}(\mathcal{N}, \mathcal{B})$ with $n \leq \dim \mathcal{M}(\mathcal{N}, \mathcal{B})$ there exists a unique representation
\[
\pi_{\phi\otimes\cdots\otimes\phi}(df_1 \otimes \cdots \otimes df_n)(\phi) \in \mathcal{B}(\mathcal{H}_{\phi\otimes\cdots\otimes\phi}).
\] (182)

The same is true for any $n$-form field, defined as a section of the fibre bundle of an antisymmetric wedge product $\wedge^n T^\phi \mathcal{E}_\phi$, because $\wedge^n T^\phi \mathcal{E}_\phi \subset \bigotimes T^\phi \mathcal{E}_\phi$. As a result, each smooth section of $\wedge^n T^\phi \mathcal{M}(\mathcal{N}, \mathcal{B})$ can be represented as a family of bounded operators,
\[
\pi_{\phi\otimes\cdots\otimes\phi} : \wedge^n T^\phi \mathcal{E}_\phi \ni \pi_{\phi\otimes\cdots\otimes\phi}(x) \in \mathcal{B}(\mathcal{H}_{\phi\otimes\cdots\otimes\phi}),
\] (183)

acting fibrewise over the $\otimes^n$-GNS bundle $(\otimes^n \mathcal{H})\mathcal{M}(\mathcal{N}, \mathcal{B})$. We will call such family a quantum $n$-form field over $\mathcal{M}(\mathcal{N}, \mathcal{B})$.

The constant function on $\Lambda^n_{\phi}$, $\hat{\lambda} : \Lambda^n_{\phi} \ni \omega \mapsto \hat{\lambda}(\omega) := \lambda \in \mathbb{R}$, is a geometric element of an algebraic element of a center of $\mathcal{N}$, $\lambda \in \mathcal{Z}_{\mathcal{N}} \subset \mathcal{N}$, in terms of an element of a smooth algebra, $\hat{\lambda} \in \mathbb{C}_F^\infty(\Lambda^n_{\phi}; \mathbb{R})$. Such function on $\Lambda^n_{\phi}$ will be called a global charge. From this it follows that, provided $\mathcal{B} \cong N^n_{\phi}$, each globally constrained source strength is a global charge.

The set of quantum field one-forms in $T^\phi \mathcal{E}_\phi$, considered under its restriction to some quantum model $\mathcal{M}(\mathcal{N}, \mathcal{B}) \subseteq \mathcal{N}^*$, can be equipped with the additional structure of a Lie algebra $\mathfrak{h}$, determined by the structure constants $\epsilon_{abc}^c$ of its adjoint representation by means of
\[
[(d_\phi f)^a, (d_\phi k)^b]_\mathfrak{h} = \sum_c \epsilon_{abc}^e(\phi)(d_\phi h)^e \quad \forall \phi \in \mathcal{M}(\mathcal{N}, \mathcal{B}).
\] (184)

Here $(d_\phi f)^a$ denotes a Lie algebra representation map $\mathfrak{h} \rightarrow (T^\phi \mathcal{E}_\phi)$ at $\phi \in \mathcal{M}(\mathcal{N}, \mathcal{B})$. Representation of these forms on the fibres of the GNS bundle gives
\[
[\pi_\phi((d_\phi f)^a), \pi_\phi((d_\phi k)^b)]_\mathfrak{h} = \sum_c \epsilon_{abc}^e(\phi)\pi_\phi((d_\phi h)^e) \quad \forall \phi \in \mathcal{M}(\mathcal{N}, \mathcal{B}).
\] (185)

Note that the Lie algebra structure given by (185) is a priori independent of any possible principal G-bundle structure of $\mathcal{H}\mathcal{M}(\mathcal{N}, \mathcal{B})$ or a principal G-bundle $E \rightarrow \mathcal{M}(\mathcal{N}, \mathcal{B})$ represented in terms of $\mathcal{H}\mathcal{M}(\mathcal{N}, \mathcal{B})$ by means of a local gauge liouvillan. In order to keep the same relationship between source terms $\lambda_i(\phi)\pi_\phi((d_\phi f_i)^a)$ in each fibre $\mathcal{H}_\phi$, one has to set $\lambda_i$ to be given by a global charge. We will call the source terms $\pi_\phi((d_\phi f_i)^a)$ local gauge quantum fields, while the corresponding local source models with global source strengths $\lambda_i$ will be called local gauge quantum field models. If an extended liouvillan model $(\mathcal{M}(\mathcal{N}, \mathcal{B}), A, a, \lambda_1, H_1, \ldots, \lambda_n, H_n)$ is equipped with an affine connection $\nabla$ such
that \((\mathcal{M}(\mathcal{N}, \mathcal{B}), \mathbf{A}, \mathbf{a}, \nabla)\) is a gauge geodesic propagation model, while \((\mathcal{M}(\mathcal{N}, \mathcal{B}), \lambda_1, H_1, \ldots, \lambda_n, H_n)\) is a quantum field model with \(H_i(\phi) = \pi_\phi((\mathbf{d}_i f_i)^{\alpha_i}) \forall i \in \{1, \ldots, n\}\), then the \((4 + 2n)\)-tuple

\[
(\mathcal{M}(\mathcal{N}), \mathbf{A}, \mathbf{a}, \nabla, \lambda_1, (\mathbf{d}_1 f_1)^{\alpha_1}, \ldots, \lambda_n, (\mathbf{d}_n f_n)^{\alpha_n})
\]

(186)
can be called a ‘quantum field model with gauge geodesic propagation’. If \(G\) and \(a\) are chosen to agree with the Wigner classification theorem, then such model describes a family of quantum fields together with a quantum particle geodesic propagation. However, while the availability of these constructions is a quite remarkable fact, it is yet unclear how they could be translated to the usual objects of quantum field theory.

### 3.4 Local liouvillean instruments and correlation functions

The temporal evolution of a local liouvillean model is completely described by the fibrewise evolution

\[
\xi(\omega, t) = e^{-it\mathcal{L}(\omega, t)}\Omega_\omega,
\]

(187)
which is a generalisation of (100) taking local gauge and local source structures on \(\mathcal{M}(\mathcal{N}) \subseteq \mathcal{N}_{\psi_0}^+\) into account. The corresponding propagator (transition amplitude) between initial state \(\omega\) and the final state \(\phi\) reads

\[
\langle \Omega_{\phi}, V_{\phi, \omega} \xi(\omega, t) \rangle_{\mathcal{H}_{\phi}} = \langle \Omega_{\phi}, V_{\phi, \omega} e^{-it\mathcal{L}(\omega, t)}\Omega_\omega \rangle_{\mathcal{H}_{\phi}}.
\]

(188)
If \(\mathcal{L}\) is determined only by a given Poisson system \((\mathcal{M}(\mathcal{N}, \mathcal{B}), h)\) with \(\mathfrak{S}_h^\psi h \in \mathcal{N}_{\psi_0} \forall \omega \in \mathcal{M}(\mathcal{N}, \mathcal{B})\), then the propagator (188) reads

\[
\langle \Omega_{\phi}, V_{\phi, \omega} e^{-it\pi_\omega(\mathfrak{S}_h^\psi(h))} \rangle_{\mathcal{H}_{\phi}} = \langle \Omega_{\phi}, e^{it \log(J_{\phi, \omega})} e^{-it\pi_\omega(\mathfrak{S}_h^\psi(h))}\Omega_\omega \rangle_{\mathcal{H}_{\phi}}.
\]

(189)

We will now show that this evolution can be expressed as an instrument acting on \(\mathcal{N}_{\psi}^+\) and parametrised by \(t \in \mathbb{R}\). Let us choose some \(\psi \in \mathcal{N}_{\psi_0}^+\). Then the elements of each fibre of the GNS bundle over \(\mathcal{N}_{\psi_0}^+\) can be uniquely mapped to \(\mathcal{H}_\psi\) by means of the standard unitary transition operator \(V_{\psi, \omega} = J_{\psi, \omega} J_{\psi, \omega} = J_{\psi, \omega} J_{\omega}\), which preserves the positive cones (see Section 2.2). Hence, at each value of \(t \in \mathbb{R}\) and at each \(\psi \in \mathcal{N}_{\psi_0}^+\), the set

\[
\bigcup_{\omega \in \mathcal{M}(\mathcal{N})} \{V_{\psi, \omega} \xi(\omega, t)\} \subseteq \mathcal{H}_{\psi}^+
\]

(190)
represents completely the evolution in a fibre bundle \(\mathcal{H}\mathcal{M}(\mathcal{N})\) that is defined by means of a local liouvillean operator. Using the bijective norm continuous homomorphism \(\xi_{\psi}^+ : \mathcal{H}_{\psi}^+ \rightarrow \mathcal{N}_{\psi_0}^+\) (defined as \(\xi_{\psi}^+ \pi = \pi_{\psi}\)), we can represent the mapping

\[
\mathbb{R} \ni t \mapsto \bigcup_{\omega \in \mathcal{M}(\mathcal{N})} \{V_{\psi, \omega} \xi(\omega, t)\} \subseteq \mathcal{H}_{\psi}^+
\]

(191)
as a temporal evolution of subsets of \(\mathcal{N}_{\psi_0}^+\),

\[
t \mapsto \xi_{\psi}^+ \left( \bigcup_{\omega \in \mathcal{M}(\mathcal{N})} \{V_{\psi, \omega} \xi(\omega, t)\} \right) \subseteq \mathcal{N}_{\psi_0}^+.
\]

(192)
The family of mappings

\[
\mathbb{R} \ni t \mapsto \left\{ J_{\mathcal{L}, \psi}(t) : \mathcal{M}(\mathcal{N}) \ni \omega \mapsto (J_{\mathcal{L}, \psi}(t))(\omega) := \xi_{\psi}^+ (V_{\psi, \omega} e^{-it\mathcal{L}(\omega, t)}\Omega_\omega) \in \mathcal{N}_{\psi_0}^+ \right\}
\]

(193)
will be called a **local liouvillean instrument** (this name may be a bit deceiving, because of nonlocality inherent in the \(V_{\phi, \omega}\) operation. The uniqueness of standard unitary transition for each pair of elements of \(\mathcal{N}_{\psi_0}^+\) together with bijectivity of \(\xi_{\psi}^+\) implies

\[
\xi_{\psi}^+ V_{\psi, \omega} \xi = \xi_{\psi}^+ V_{\psi, \omega} \xi \quad \forall \xi \in \mathcal{H}_\omega \forall \psi, \omega \in \mathcal{N}_{\psi_0}^+.
\]

(194)
hence an extended liouvillean instrument does not depend on the choice of \( \psi \). In what follows we will denote it by \( \mathcal{I}_{\mathcal{L}(t)} \). Due to bijectivity of \( \zeta_t^\phi \), there is an equivalence between the evolution generated on the GNS bundle by the family of extended liouvillean operators and the evolution generated on \( \mathcal{N}_0^+ \) by the extended liouvillean instrument. Thus, one can consider the extended liouvillean operator structure over a given model (including local gauge and local source structures, as well as the isometry \( \alpha_* \) or a Poisson flow \( \omega^B \)) as auxiliary tools allowing to define suitable extended liouvillean instrument, but otherwise devoid of any foundational meaning.

The GNS bundle allows to construct the \( n \)-point correlation functions, whenever all quantum states under consideration are faithful. Let \( \mathcal{N} \) be a W*-algebra, let \( \phi_0, \phi_1, \ldots, \phi_n \in \mathcal{N}_0^+ \) and let \( x_1, \ldots, x_n \in \mathcal{N} \). Then we can define the \textbf{time independent \( n \)-point correlation function} as

\[
\langle x_1(\phi_1) \cdots x_n(\phi_n) \rangle_{\phi_0} := \Omega_{\phi_0}, V_{\phi_0,\phi_1} \pi_{\phi_1}(x_1) \cdots V_{\phi_{n-1},\phi_n} \pi_{\phi_n}(x_n)V_{\phi_n,\phi_0} \Omega_{\phi_0} \rangle_{\mathcal{H}_{\phi_0}}.
\]

If \( \mathcal{M}(\mathcal{N}) \subseteq \mathcal{N}_0^+ \) is \( m \)-dimensional, \( \phi_0, \phi_1, \ldots, \phi_n \in \mathcal{M}(\mathcal{N}) \) and \( \theta : \mathcal{M}(\mathcal{N}) \to \mathbb{R}^m \) is a coordinate system on \( \mathcal{M}(\mathcal{N}) \), then (195) can be expressed in terms of \( \theta \) as

\[
\langle x_1(\theta_1) \cdots x_n(\theta_n) \rangle_{\phi(\theta_0)} := \Omega_{\phi_0}, V_{\phi_0,\phi(\theta_1)} \pi_{\phi(\theta_1)}(x_1) \cdots V_{\phi_{n-1},\phi_n} \pi_{\phi_n}(x_n)V_{\phi_n,\phi(\theta_0)} \Omega_{\phi_0} \rangle_{\mathcal{H}_{\phi(\theta_0)}},
\]

where \( \theta_0, \theta_1, \ldots, \theta_n \in \mathbb{R}^m \) and \( \phi_1 = \phi(\theta_1) := \theta^{-1}(\theta_1) \). Constructions provided in this paper allow us to define also the \textbf{time dependent \( n \)-point correlation functions} as

\[
\langle x_1(\phi_1, t_1) \cdots x_n(\phi_n, t_n) \rangle_{\phi_0} := \Omega_{\phi_0}, V_{\phi_0,\phi(\theta_1)} e^{i t_1 \mathcal{L}(\phi(\theta_1), t_1)} \pi_{\phi(\theta_1)}(x_1) e^{-i t_1 \mathcal{L}(\phi(\theta_1), t_1)} \cdots V_{\phi_{n-1},\phi_n} e^{i t_n \mathcal{L}(\phi_n, t_n)} \pi_{\phi_n}(x_n) e^{-i t_n \mathcal{L}(\phi_n, t_n)} V_{\phi_n,\phi(\theta_0)} \Omega_{\phi_0} \rangle_{\mathcal{H}_{\phi(\theta_0)}},
\]

where \( t_1, \ldots, t_n \in \mathbb{R} \) and \( \mathcal{L}(\phi, t) \) is an extended liouvillean. If a reformulation in terms of a coordinate system \( \theta \) (defined above) is possible, then (197) can be expressed as

\[
\langle x_1(\theta_1, t_1) \cdots x_n(\theta_n, t_n) \rangle_{\phi(\theta_0)} = \Omega_{\phi(\theta_0)}, V_{\phi(\theta_0),\phi(\theta_1)} e^{i t_1 \mathcal{L}(\phi(\theta_1), t_1)} \pi_{\phi(\theta_1)}(x_1) e^{-i t_1 \mathcal{L}(\phi(\theta_1), t_1)} \cdots V_{\phi(\theta_{n-1}),\phi(\theta_n)} e^{i t_n \mathcal{L}(\phi_n, t_n)} \pi_{\phi_n}(x_n) e^{-i t_n \mathcal{L}(\phi_n, t_n)} V_{\phi_n,\phi(\theta_0)} \Omega_{\phi(\theta_0)} \rangle_{\mathcal{H}_{\phi(\theta_0)}},
\]

Due to different values taken by the components of \( \mathcal{L} \) operator at different points \((\phi, t)\), the evolution determined by (187) and (197) does not have to be unitary. It is so only when the dynamics and perturbations in all fibres of the Hilbert bundle are the same.

Equation (197) describes how the predictive time dependent content of a quantum model \( \mathcal{M}(\mathcal{N}) \) can be determined using the representation of geometric structures on \( \mathcal{M}(\mathcal{N}) \) in terms of the algebraic structures on the GNS bundle. However, let us note that this equation is only an example of the variety of possible definitions of the time dependent correlation functions that could be constructed with the help of local liouvillians and the GNS bundle. Moreover, one could carry the above constructions also for MCP bundle, obtaining different quantitative results. The identification of the proper construction should be based on a more detailed analysis of backwards compatibility with other approaches. In next Section we will approach the derivation of the path integral analogue of the propagator (188).

4 Quantum histories

In order to solve the problems of ‘measurement’ and ‘time’ in quantum theory Griffiths [125], Omnès [257, 258, 259, 260, 261, 262, 263], and Gell-Mann and Hartle [108, 109, 107, 134, 135, 110, 136] have developed ‘consistent histories’ approach to quantum theory. Isham and Linden [159, 160, 161, 162, 163] have proposed a modification of this approach, called the (continuous-time) ‘history projection operator’ approach, which was developed later by Savvidou and Anastopoulos [297, 298, 12, 11, 13].
In Section 4.1 we will recall the elementary mathematical structure of the Isham–Linden approach, in Section 4.2 we will discuss Savvidou’s construction [297, 298] of an action operator within this setting, while in Sections 4.3 and 4.4 we will follow the Anastopoulous–Savvidou analysis of the relationship of this framework with the geometric structures on the spaces of pure quantum states, and the Daubechies–Klauder [77, 194, 365] continuous-time regularised coherent states phase space path integration. Sections 4.1-4.4 do not contain new results. Their aim is to lead us to a refined geometric perspective on the relationship between the Daubechies–Klauder formula and the local liouvillanese. In Section 4.5 we will apply the local liouvillan approach to the Falcone–Takesaki construction of noncommutative flow of weights in order to construct the algebraic analogue of Savvidou’s histories action operator. The discussion of limitations of this construction in the face of the results of Section 3 will lead us to construction of $W^*$-geometric generalisation of the Daubechies–Klauder path integration in Section 4.6.

4.1 Propositions and evolution

The starting point of the history projection operator approach is consideration of a `history’ $\varpi$ of abstract ‘propositions’ $(P_1, P_2, \ldots, P_n)$ about a quantum theoretic model, assigned to an ordered finite sequence $(t_1, t_2, \ldots, t_n)$, where $t_1 < t_2 < \ldots < t_n$, and $t$ is interpreted as ‘time’ parameter. Following the ideas of Mittelstaedt [242] and Stachow [332, 333], Isham [159] has proposed to specify this entity by the projection operator

$$P_\varpi := P_{t_1} \otimes P_{t_2} \otimes \ldots \otimes P_{t_n},$$

acting on the Hilbert space

$$\mathcal{V}_n := \bigotimes_{i=1}^{n} \mathcal{H}_{t_i} := \mathcal{H}_{t_1} \otimes \mathcal{H}_{t_2} \otimes \ldots \otimes \mathcal{H}_{t_n},$$

where $P_{t_i}$ is a projection operator in the $n$-th copy of the Hilbert space $\mathcal{H}_{t_i} := \mathcal{H}$ of a given quantum model. The history $\varpi$ of nonunitary propositions as well as the description of the unitary dynamics are contained in the class operator on $\mathcal{V}_n$, defined as [108]

$$C_\varpi := U(t_0, t_1)P_{t_1}U(t_1, t_2)P_{t_2} \cdots U(t_{n-1}, t_n)P_{t_n}U(t_n, t_0),$$

where $U(t_i, t_{i+1}) = e^{-i\int_{t_i}^{t_{i+1}} dt H}$ are unitary evolution operators between times $t_i$ and $t_{i+1}$, acting on the Hilbert space $\mathcal{H}_{t_{i+1}}$ and generated by a self-adjoint hamiltonian operator $H$. For a dynamics generated by the hamiltonian $H$ with an initial state described by the density operator $\rho$, the probability of a history $\varpi$ is defined as

$$p(\varpi; \rho, H) := \text{tr}_{\mathcal{V}_n}(C_\varpi^\ast \rho C_\varpi).$$

Using this equation, for two given histories $\varpi$ and $\vartheta$, one defines the histories functional$^{30}$ [125]

$$\delta_{\rho, H} : \mathfrak{B}(\mathcal{V}_n) \times \mathfrak{B}(\mathcal{V}_n) \ni (P_\varpi, P_\vartheta) \mapsto \text{tr}_{\mathcal{V}_n}(C_\varpi^\ast \rho C_\vartheta) \in \mathbb{C},$$

which, by definition, depends on $\rho$ and $H$. It satisfies, for $P_\varpi \leq 1 - P_\vartheta$,

$$\delta_{\rho, H}(P_\varpi, P_\vartheta) \geq 0,$$

$$\delta_{\rho, H}(P_\varpi, P_\vartheta) = \delta_{\rho, H}(P_\vartheta, P_\varpi)^*,$$

$$\delta_{\rho, H}(0, P_\varpi) = 0,$$

$$\delta_{\rho, H}(1, 1) = 1,$$

$$\delta_{\rho, H}(P_\varpi + P_\vartheta, P_\vartheta) = \delta_{\rho, H}(P_\varpi, P_\vartheta) + \delta_{\rho, H}(P_\vartheta, P_\vartheta).$$

$^{30}$For historical reasons, this object is usually called ‘decoherence functional’. However, such name suggests that the quantum histories formalism necessary involves the ‘decoherence approach to quantum measurement’ semantics, which is not true. For this reason we choose to change the name of this mathematical object to much more neutral with respect to possible semantics.
Description of a quantum theoretic model provided in terms of the class operator and histories functional is intended to serve as a single replacement for dualistic description of temporal behaviour of model in terms of Schrödinger’s and von Neumann–Lüders’ equations.

The Born–Jordan–Dirac–Heisenberg (BJDH) algebra \([41, 40, 84]\), generated by the canonical commutation relations
\[
[q, q] = 0, \quad [p, p] = 0, \quad [q, p] = i\mathbb{I},
\]
(209)
is extended in the quantum histories framework to an algebra generated by the relations:
\[
[q_t, q_{t'}] = 0, \quad [p_t, p_{t'}] = 0, \quad [q_t, p_{t'}] = i\delta_{t,t'}\mathbb{I},
\]
(210)
where the operators \(q_t\) and \(p_t\) are considered as operators defined in the Schrödinger picture for different moments \(t_i\) of time, acting on the Hilbert space \(\mathcal{H}_t\), while \(\mathbb{I}\) is a unit element of that algebra. 

In order to formulate an extension of this formalism to the case of a continuous time \(t \in \mathbb{R}\), Isham and Linden \([161]\) have changed the above relations to the form of the so-called history algebra:
\[
[q_f, q_g] = 0, \quad [p_f, p_g] = 0, \quad [q_f, p_g] = i\int_{-\infty}^{+\infty} df(t)g(t)\mathbb{I},
\]
(211)
where \(q\) and \(p\) are operator valued distributions, \(f, g \in L_2(\mathbb{R}, dt)\), \(p_f := p(f)\), \(q_f := q(f)^{31}\).

Isham and Linden \([160, 162]\) (see also \([297]\)), have shown that these commutation relations may be represented on the Hilbert \(\)continuous history space\)
\[
\mathcal{V} := \bigotimes_{t \in \mathbb{R}} \mathcal{H}_t := \bigotimes_{t \in \mathbb{R}} (L_2(\mathbb{R}, dx))_t.
\]
(213)

The ‘continuous tensor product’ space \(\bigotimes_{t \in \mathbb{R}} \mathcal{H}_t\) is defined to be the symmetric Fock-Cook space \([104, 75]\)
\[
\mathfrak{F}[\mathcal{H}] = \mathfrak{F}[L_2(\mathbb{R}, dx)] = \bigoplus_{n=0}^{\infty} \text{sym}_n \left( \bigotimes_{k=0}^{n} L_2(\mathbb{R}, dx) \right),
\]
(214)
where \(\bigotimes_{0} L_2(\mathbb{R}, dx) := \mathbb{C}\),
\[
\text{sym}_n : \xi_1 \otimes \ldots \otimes \xi_n \mapsto \frac{1}{\sqrt{n!}} \sum_{s \in \mathfrak{S}(n)} \xi_{s(1)} \otimes \ldots \otimes \xi_{s(n)}
\]
(215)
and \(\mathfrak{S}(n)\) is the group of permutations of the set \(\{1, \ldots, n\}\). The history of \((t_1, \ldots, t_n)\) is represented by the vector of \(\mathfrak{F}[\mathcal{H}]\) generated by the action of \(n\) ‘creation operators’
\[
b^*_k(f) : \mathfrak{F}[\mathcal{H}] \ni \text{sym}_n(\xi_1 \otimes \ldots \otimes \xi_n) \mapsto \sqrt{n + 1}\text{sym}_{n+1}(f \otimes \xi_1 \otimes \ldots \otimes \xi_n) \in \mathfrak{F}[\mathcal{H}],
\]
(216)
which, together with the ‘annihilation operators’
\[
b_k(f) : \mathfrak{F}[\mathcal{H}] \ni \text{sym}_n(\xi_1 \otimes \ldots \otimes \xi_n) \mapsto \frac{1}{\sqrt{n+1}} \sum_{k=1}^{n} f \cdot \text{sym}_{n-1}(\xi_1 \otimes \ldots \otimes \xi_{k-1} \otimes \xi_{k+1} \otimes \ldots \otimes \xi_n) \in \mathfrak{F}[\mathcal{H}],
\]
(217)
satisfy
\[
[b_k(f), b_{k'}(g)] = 0 = [b^*_k(f), b^*_{k'}(g)], \quad [b_{k'}(f), b^*_k(g)] = \int_{-\infty}^{+\infty} df(t)g(t)\mathbb{I}
\]
(218)
\[\text{31Correspondingly, in the histories approach to quantum field theory one considers the ‘field’ operator-valued distributions }q \text{ and } p \text{ which act on a subspace of } L_2(\mathbb{R}^3, d^3x), \text{ where the parameter } \vec{x} \in \mathbb{R}^3 \text{ is interpreted as representing a three-dimensional ‘space’, and extends the canonical commutation relations at single point of time with the additional dependence on time dimension handled by the histories algebra } [161, 162, 297]. \text{ When the dependence on the functions in } L_2(\mathbb{R}^3, d^3x) \text{ is made implicit, these relations read}
\]
\[
[q_t(\vec{x}_1), q_t(\vec{x}_2)] = 0, \quad [p_t(\vec{x}_1), p_t(\vec{x}_2)] = 0, \quad [q_t(\vec{x}_1), p_t(\vec{x}_2)] = i\delta(t_1 - t_2)\delta^3(\vec{x}_1 - \vec{x}_2).\]
(219)
This means that the three-dimensional histories commutation relations are actually three-plus-one-dimensional canonical commutation relations.
on the common domain $\mathcal{D} \subset \mathcal{H}$. Moreover, it is assumed that there exists a unit vector $\Omega \in \mathcal{D}$ such that
\[ b_i(f)\Omega = 0 \quad \forall t \in \mathbb{R} \quad \forall f \in \mathcal{H}. \] (219)

These assumptions define the Isham–Linden representation of the history algebra (211) to be the Fock–Cook representation. The spectral projectors of this representation of histories algebra are interpreted as propositions about the temporal histories of a given quantum theoretic model.

For a given Hamiltonian $H_t$, the self-adjoint histories Hamiltonian operator in the Schrödinger picture is defined as
\[ H_\kappa := \int_{-\infty}^{+\infty} dt \kappa(t) H_t, \] (220)
where $\kappa(t) \in L_2(\mathbb{R}, dt)$ is a function which ‘smears’ $H_t$ in time. The histories algebra generates the commutation relations with this Hamiltonian.

The Araki theorem [14] states the existence and uniqueness of Hamiltonian operator in the Fock–Cook representation if this operator (if unsmeared) has a form
\[ H_t = \frac{p_t^2}{2m} + \frac{mw^2q_t^2}{2}, \] (221)
where $p_t = \sqrt{\frac{m}{2}} q_t + i \sqrt{\frac{1}{4mw^2}} p_t$.

Anastopoulos [11] has shown that the construction of the continuous history Hilbert space $\mathcal{V}$ and the representation of the history algebra in $\mathcal{V}$ can be provided also for nonquadratic Hamiltonians using the coherent states representation [308, 116]. However, such representation lacks any characterisation of its uniqueness.

4.2 Savvidou’s action operator

The important property of the histories approach, discovered by Savvidou [297], is the existence of the self-adjoint quantum action operator, acting on $\mathcal{V}$ and defined as
\[ S_{\lambda,\kappa} := \int_{-\infty}^{+\infty} dt (\lambda(t)p_t \dot{q}_t - \kappa(t) H_t), \] (225)
by an analogy to a Hamilton–Jacobi action functional in classical mechanics theory
\[ S_{\text{HJ}} = \int_{t_1}^{t_2} dt (p_\Gamma(t) \dot{q}_\Gamma(t) - H_\Gamma(t)), \] (226)
where $p_\Gamma, q_\Gamma, H_\Gamma \in C^\infty(\Gamma)$, and $\Gamma$ is a classical mechanics phase space. In both these equations, the dot symbol denotes the differentiation $\frac{d}{ds}$ with respect to to time parameter $s$ of the evolution generated by hamiltonian, that is (in the quantum theory)

$$q_t := q_t(s) := e^{isH_t}q_te^{-isH_t}, \quad (227)$$

$$\dot{q}_t := \frac{d}{ds}q_t(s). \quad (228)$$

Savvidou has shown that there also exists the *Liouville operator*

$$V := \int_{-\infty}^{+\infty} dt \tilde{V}_t := \int_{-\infty}^{+\infty} dt (p_t \dot{q}_t), \quad (229)$$

which is self-adjoint on $\mathcal{V}$. Hence, for $\lambda(t) \equiv 1$, one may express the action operator as

$$S_\kappa = V - H_\kappa = \int_{-\infty}^{+\infty} dt p_t \dot{q}_t - \int_{-\infty}^{+\infty} dt \kappa(t)H_t \quad (230)$$

with the following commutation relations:

$$[S_\kappa, H_\nu] = iH_\nu', \quad [S_\kappa, V] = -iH_\kappa, \quad [V, H_\kappa] = -iH_\kappa. \quad (231)$$

For $\kappa(t) \equiv 1$ the histories quantum theory reduces to ordinary quantum theory, which (for $H := \int_{-\infty}^{+\infty} dt H_t$) is reflected in the commutators $[V, H] = 0$ and $[V, S] = 0$.

The operator $V$ acts on $b_t$ in the following way [297]:

$$e^{irV}b_f(t)e^{-irV} = b_{f(t+r)}. \quad (232)$$

Moving to the Heisenberg picture, one can compare the action of $V$, $H_t$ and $S$:

$$e^{irV}b_t(s)e^{-irV} = b_{t+r}(s), \quad (233)$$

$$e^{i\rho H_t}b_t(s)e^{-i\rho H_t} = b_{t+r}(s), \quad (234)$$

$$e^{i\rho S}b_t(s)e^{-i\rho S} = b_{t+r}(s), \quad (235)$$

where the ‘smeared’ operator $S_\kappa$ acts by an automorphism

$$e^{i\rho S_\kappa}b_f(t)e^{-i\rho S_\kappa} = b_{\Sigma_\kappa(f)}, \quad (236)$$

where $\Sigma_\kappa$ is an unitary operator acting on $\zeta \in L_2(\mathbb{R}, dt)$ by

$$(\Sigma_\kappa \zeta)(t) := e^{-i\int_t^{t+r} d\kappa(t')}\zeta(t+r), \quad (237)$$

For not smeared $b_t$ this can be formally written as

$$\Sigma_\kappa b_t e^{-i\rho S_\kappa} = e^{-i\int_t^{t+r} d\kappa(t')} \frac{d}{dt} b_t, \quad (238)$$

where the self-adjoint generator $S_\kappa$ on $\mathfrak{g}[L_2(\mathbb{R}, dt)]$ corresponds to an action of self-adjoint $\sigma_\kappa$ on $L_2(\mathbb{R}, dt)$ given by

$$\sigma_\kappa \zeta(t) := -\left( -\omega\kappa(t) - i\frac{d}{dt}\right) \zeta(t). \quad (239)$$

The map $\mathbb{R} \ni r \mapsto e^{i\rho S_\kappa}$ is a weakly continuous representation of a one-parameter family of unitary operators. In the same way the action of the automorphism generated by the Liouville operator $V$

$$e^{i\rho V}b_f(t)e^{-i\rho V} = b_{f(t+r)} \quad (240)$$
corresponds to the action of
\[ (v_r \zeta)(t) := e^{i \frac{d}{dt} \zeta(t)} = \zeta(t + r) \] (241)
on \zeta \in L^2(\mathbb{R}, dt).

Hence, \( V \) transforms \( b_t \) from time \( t \), related with the Hilbert space \( \mathcal{H}_t \), to time \( t + r \), related with the Hilbert space \( \mathcal{H}_{t+r} \) (strictly speaking, \( V \) transforms the support of the operator valued distribution). This is, by definition, purely kinematical operation, which does not depend on the hamiltonian \( H_t \). On the other hand, \( H_t \) generates the unitary evolution of the system in the single space \( \mathcal{H}_t \subset \mathcal{V} \). The action operator (230) joins together these two types of transformations. This is in some sense analogous to the Hamilton–Jacobi formulation of classical mechanics, in which the Hamilton–Jacobi action functional (226) is the generator of a canonical transformation of the classical mechanical model from one time to another.

Savvidou [297] suggests that these two operators \( (V \text{ and } H_\alpha) \) are related respectively with two different types of time evolution: the nonunitary ‘reduction’ (Lüders’ rule) related with subsequent propositions \( P_t \), and the ordinary hamiltonian evolution (Schrödinger’s equation) given by operators \( e^{isHt} \). However, the projection operators \( P_t \), class operators \( C_\omega \), and histories functional \( J_{\rho,H} \) were used neither in derivation of the kinematical evolution related with the Liouville operator \( V \), nor in derivation of the quantum action operator \( S_\kappa \). This is reflected in the apparent unitary character of the corresponding temporal evolutions generated by \( V \) and \( S_\kappa \). Hence, so far this suggestion has been ungrounded. In the next two subsections we will follow Anastopoulos and Savvidou on their way of reintroduction of nonunitary elements in quantum histories formalism.

4.3 Geometric phase as a trace of a history

There exists a class of quantities in quantum theory, which do not correspond to any element of an algebra of operators, but are nevertheless very closely related to quantitative results of experimental procedures. One of the important representatives of this class is the geometric phase. It reflects the geometric structure of the Hilbert space. Mathematically, it is defined as a holonomy of the Berry connection on the Hopf bundle [326]. The Hopf bundle is a \( U(1) \) principal bundle of the Hilbert space \( \mathcal{H} \) over the projective Hilbert space \( \mathbb{P}\mathcal{H} \subset \mathcal{H} \). In other words, it is a principal bundle of the subspaces \( \mathcal{H}_P \) of vectors in \( \mathcal{H} \) over the space of generating rays of \( \mathcal{H} \). The Berry connection \( \nabla^P \) is defined as a \( U(1) \) connection 1-form on the Hopf bundle, induced naturally by an inner product on the Hilbert space \( \mathcal{H} \), and given in the coordinate-free form by
\[ \nabla^P := \langle \cdot, d\cdot \rangle_\mathcal{H} : \mathcal{H} \times \mathcal{H} \ni (\zeta, \xi) \mapsto i \langle \zeta, d\xi \rangle_\mathcal{H} \in \mathbb{C}. \] (242)
The geometric phase (called also the Pancharatnam–Berry phase [265, 33]) is then defined as
\[ e^{i\theta[\gamma]} := e^{-\frac{i}{\hbar} \int_\gamma \langle \cdot, d\cdot \rangle_\mathcal{H}}, \] (243)
where \( \gamma \) is a closed path in \( \mathbb{P}\mathcal{H} \). We will denote a path generated by family of vectors \( \mathbb{R} \ni t \mapsto \zeta(t) \in \mathcal{H} \) by \( \zeta(\cdot) \). In case of open paths \( \zeta(\cdot) \) in \( \mathbb{P}\mathcal{H} \) it was shown in [2] and [296] that the geometric phase (called also the Aharonov–Anandan phase) is given by
\[ e^{i\theta[\gamma]} = e^{-\frac{i}{\hbar} \int_0^1 dt \langle \zeta(t), d\zeta(t) \rangle_\mathcal{H} \langle \zeta(t), \zeta(t) \rangle_\mathcal{H}}. \] (244)

Consider now an initial vector \( \zeta(t = 0) \), the final vector \( \zeta(t = r) \), equal to the initial one up to phase, and the unitary time evolution \( U(s) \) on \( \mathcal{H} \), described by the solution of the Schrödinger equation with the hamiltonian \( H \),
\[ U(r) : \zeta(t = 0) \mapsto \zeta(t = r) := e^{-irH}\zeta(t = 0), \] (245)
which acts along a loop \( \gamma(t), t \in [0, r] \), on the space \( \mathbb{P}\mathcal{H} \). The phase on the Hopf bundle is then transformed into
\[ e^{i\int_0^r dt \langle \zeta(t), -\frac{d}{dt} + iH\zeta(t) \rangle_\mathcal{H} = e^{-\frac{i}{\hbar} \int_0^1 dt \langle \zeta, d\zeta \rangle_\mathcal{H} e^{-i\int_0^r dt \langle \zeta(t), H\zeta(t) \rangle_\mathcal{H}} = e^{i\theta[\gamma]} e^{-i\int_0^r dt \langle \zeta(t), H\zeta(t) \rangle_\mathcal{H}}}. \] (246)
The first term, given by the geometric phase, does not refer to dynamics generated by the hamiltonian \( H \), and reflects purely geometric structure of the kinematical Hilbert space \( \mathcal{H} \).

Following Anastopoulos and Savvidou [12], one can analyse the geometric phase from the perspective of quantum histories. Consider first a quantum model with a hamiltonian \( H = 0 \). For a given history \( \varpi \) of the projections \( \{ P_{t_0}, P_{t_1}, \ldots, P_{t_n} \} \), where \( P_{t_i} \) is a projection onto one dimensional vector subspace of \( \mathcal{H} \) spanned by \( \zeta_{t_i} \), the trace of the class operator is

\[
\text{tr}_V(C_{\varpi}) = \langle \zeta_{t_0}, \zeta_{t_n} \rangle_{\mathcal{H}} \langle \zeta_{t_1}, \zeta_{t_0} \rangle_{\mathcal{H}} \langle \zeta_{t_2}, \zeta_{t_1} \rangle_{\mathcal{H}} \cdots \langle \zeta_{t_n}, \zeta_{t_{n-1}} \rangle_{\mathcal{H}},
\]

while the corresponding histories functional

\[
\mathcal{H}_{\{\zeta_{t_0}\times\zeta_{t_n}\}, H = 0}(P_{\zeta(\cdot)}, P_{\xi(\cdot)}) = \langle \zeta_{t_0}, \zeta_{t_{n-1}} \rangle_{\mathcal{H}} \cdots \langle \zeta_{t_1}, \zeta_{t_0} \rangle_{\mathcal{H}} \langle \zeta_{t_0}, \xi_{t_{1}} \rangle_{\mathcal{H}} \cdots \langle \xi_{t_{m-1}}, \xi_{t_m} \rangle_{\mathcal{H}}
\]

is a \((n + m + 1)\) Bargmann invariant [23, 327, 13]. Assuming that \( \delta t := \sup\{ |t_i - t_{i-1}| \} \approx O(\frac{1}{n}) \), one can approximate \( \{ \zeta_{t_i} \}_{i=1}^n \) by the path \( \zeta(t) \) on \( \mathcal{P}\mathcal{H} \), and for large \( n \) this gives

\[
\log \text{tr}_V(C_{\varpi}) = \log \langle \zeta_{t_0}, \zeta_{t_n} \rangle_{\mathcal{H}} - \sum_{i=1}^{n} \log \langle \zeta(t_i), \zeta(t_{i-1}) \rangle_{\mathcal{H}} = \log \langle \zeta_{t_0}, \zeta_{t_n} \rangle_{\mathcal{H}} - \sum_{i=1}^{n} \langle \zeta(t_i), \xi(t_i) - \zeta(t_{i-1}) \rangle_{\mathcal{H}} + O(n^{-2}),
\]

hence

\[
\lim_{\delta t \to 0} \log \left( \text{tr}_V(C_{\varpi}) \right) = \log \langle \zeta_{t_0}, \zeta_{t_n} \rangle_{\mathcal{H}} - \int_{\zeta_{t_0}}^{\zeta_{t_n}} \langle \zeta(t), d\zeta(t) \rangle_{\mathcal{H}},
\]

where the last term is the Stieltjes integral. Comparing this result with equation (244), one can see that for any path which allows for the definition of the Stieltjes integral, the trace of a class operator is equal to a geometric phase (244):

\[
\text{tr}_V(C_{\varpi}) = e^{i\theta_{\zeta(\cdot)}}.
\]

Hence, for a given history \( \varpi \), its corresponding geometric phase is defined by the trace of a class operator. Observing that \( C_{\varpi} \) is used in the definition (203) of the histories functional, one can rewrite the latter in terms of the geometric phase:

\[
\mathcal{H}_{\rho_{t_0}, H = 0}(P_{\zeta(\cdot)}, P_{\xi(\cdot)}) = \langle \zeta(t_0), \rho_{t_0} \xi(t_0) \rangle_{\mathcal{H}} \langle \zeta(t_n), \xi(t_n) \rangle_{\mathcal{H}} e^{-\frac{1}{2} \int_{t_0}^{t_n} dt \langle \zeta(t), \frac{d\zeta(t)}{dt} - H \zeta(t) \rangle_{\mathcal{H}} - \frac{1}{2} \int_{t_0}^{t_n} dt \langle \xi(t), \frac{d\xi(t)}{dt} \rangle_{\mathcal{H}} - \int_{t_0}^{t_n} dt \langle \zeta(t), H \zeta(t) \rangle_{\mathcal{H}}},
\]

For a quantum theoretical model with a nonzero hamiltonian \( H \) the histories functional is equal to [12]:

\[
\mathcal{H}_{\rho_{t_0}, H}(P_{\zeta(\cdot)}, P_{\xi(\cdot)}) = \langle \zeta(t_0), \rho_{t_0} \xi(t_0) \rangle_{\mathcal{H}} \langle \zeta(t_n), \xi(t_n) \rangle_{\mathcal{H}} e^{i(S^*[\zeta(\cdot)] + S^*[\xi(\cdot)])},
\]

where

\[
\langle S^*[\zeta(\cdot)] \rangle := \int_{t_0}^{t_n} dt \langle \zeta(t), (H - i \frac{d}{dt} \zeta(t) - H \zeta(t)) \rangle_{\mathcal{H}} = i \int_{t_0}^{t_n} dt \langle \zeta(t), \frac{d\zeta(t)}{dt} \rangle_{\mathcal{H}} - \int_{t_0}^{t_n} dt \langle \zeta(t), H \zeta(t) \rangle_{\mathcal{H}}.
\]

This agrees with the earlier result of Isham and Linden [161], who have constructed a special case of histories functional \( \mathcal{H}_{\rho, H} \). Using the continuous time projection operator on \( V \) corresponding to coherent states and using the technical assumption of \( t_0 \to -\infty \) and \( t_n \to +\infty \), they have obtained

\[
\mathcal{H}_{\rho, H}(P_{\zeta(\cdot)}, P_{\xi(\cdot)}) = \langle \zeta(t_0), \rho_{t_0} \xi(t_0) \rangle_{\mathcal{H}} e^{i \int_{t_0}^{t_n} \langle \zeta(t), \frac{d\zeta(t)}{dt} \rangle_{\mathcal{H}} - \langle \zeta(t), \frac{d\xi(t)}{dt} \rangle_{\mathcal{H}} - \langle \zeta(t), H \xi(t) \rangle_{\mathcal{H}} + \langle \zeta(t), H \zeta(t) \rangle_{\mathcal{H}}},
\]

where \( \int_{t_0}^{t_n} \langle \zeta(t), d\zeta(t) \rangle \) is a Stieltjes integral. In order to compare the equation (254) with the action equation (230), consider the Schrödinger representation of the histories algebra (210), provided by the
operators \( p_t = -i \frac{\partial}{\partial x_t} \) and \( q_t = x_t \), acting on the space \( L_2(\mathbb{R}, dx_t) \). Then \( \tilde{V}_t = p_t \hat{q}_t = -i \frac{d}{dt} \), and the equation (255) can be written in the form

\[
\langle S^* [\zeta (\cdot)] \rangle = -\int_{t_0}^{t_n} dt \langle \zeta (t), (p_t \hat{q}_t + H) \zeta (t) \rangle_{\mathcal{H}}
\]  

(257)

if it is assumed that \( t = s \) and \( \frac{d}{dt} = \frac{d}{ds} \). This equation shows that the nonhamiltonian part of the action \( S \) is reflected in the geometric phase.

According to Anastopoulos and Savvidou, the complete form of histories functional can be reconstructed by summing over all paths \( \zeta (\cdot) \) and \( \xi (\cdot) \) that are compatible with the given histories \( \zeta \) and \( \vartheta \) respectively:

\[
\delta_{\rho,H}(P_{\rho}, P_{\vartheta}) = \sum_{\zeta (\cdot) \in \Xi} \sum_{\xi (\cdot) \in \Theta} \delta_{\rho,H}(P_{\zeta (\cdot)}, P_{\xi (\cdot)}) .
\]

(258)

In face of the above results, they conclude, that «the knowledge of the geometric phase—for a set of histories and of the automorphism that implements the dynamics—is sufficient to fully reconstruct the decoherence [histories] functional—and hence all the probabilistic content of the [histories approach to quantum] theory» [12]. In other words, the histories approach provides the complete description of temporal behaviour of quantum theoretic models using two levels of description: the unitary action automorphism and the histories functional, which incorporates the nonunitary changes of geometry of the Hilbert space related with the sequences of projection operators taken into consideration.

However, this result is not completely clear. The functional \( \langle S^* [\zeta (\cdot)] \rangle \), despite the suggestive notation, is not the expectation value of the adjoint of the action operator \( S_\kappa \) (225), unless \( \int_{-\infty}^{\infty} dt \) is introduced consistently at some stage of derivation of (257). Moreover, the assumption \( t = s \) is not justified by any reasons other than \textit{ad hoc} decision. It is unsatisfactory that in order to derive the relationship of two different temporal evolutions with the geometric phase one has to set the values of corresponding time parameters to be identical. There also remains the question to what extent several different technical assumptions used in the construction of \( S_\kappa \) and \( \langle S^* [\zeta (\cdot)] \rangle \) are essential for the final results and conclusions. Moreover, it is problematic to what extent the operator \( V \) can be related with the 'external time' \textit{without} introducing the family of projections \( P_t \) and the object \( \langle S^* [\zeta (\cdot)] \rangle \). By definition, the operators \( V \) and \( S_\kappa \) refer only to continuous number of copies of the same Hilbert space, but without any reference to projections or 'measurements'.

Finally, these results are based on the arbitrary choice of the particular Fock–Cook (or coherent states) representation of histories version of the BJDH commutation relations. If the number of degrees of freedom of the algebra is finite, then the Stone–von Neumann [335, 360] theorem guarantees that the Schrödinger representation of the Weyl form of the BJDH algebra of canonical commutation relations is a unique, up to unitary equivalence, irreducible representation. However, in the infinite-dimensional case there exists uncountable many different unitarily inequivalent irreducible representations of this algebra [121, 375]. Hence, the choice of a particular representation provides a nontrivial decision problem and should be justified by some argument, but there is no such argument at sight. In order to resolve these problems we have to move to a more general approach to quantum theory, the algebraic approach.

4.4 Hilbert space geometry and coherent state path integrals

In this subsection we will discuss the basic aspects of the geometric approach to the formalism of the Hilbert space based quantum theory [344, 236, 191, 69, 326, 68, 142, 264, 2, 10, 70, 111, 71, 147, 148, 299, 102, 103, 45, 21, 67, 46, 65, 29] and its relationship with the description of temporal behaviour of quantum theoretic models in the Hilbert space based quantum histories approach.

Every complex Hilbert space \( \mathcal{H} \) can be considered as the real Hilbert space of double dimension, equipped with a complex structure operator \( j^\mathcal{H} : \mathcal{H} \to \mathcal{H} \) such that \( (j^\mathcal{H})^2 = -\mathbb{I} \) and \( \langle \xi, j^\mathcal{H} \zeta \rangle_\mathcal{H} = \langle \zeta, \xi \rangle_\mathcal{H} \).
i\langle \zeta, \zeta \rangle_{\mathcal{H}} [345]. The decomposition of the inner product on \mathcal{H} into real and imaginary parts,

\begin{align}
\text{re} \langle \xi, \zeta \rangle_{\mathcal{H}} &= \frac{1}{2} g^{\mathcal{H}}(\xi, \zeta), \\
\text{im} \langle \xi, \zeta \rangle_{\mathcal{H}} &= \frac{1}{2} w^{\mathcal{H}}(\xi, \zeta),
\end{align}

(259)
(260)
equis the real Hilbert space \mathcal{H} with the structure of the nondegenerate positive definite real inner product \( g^{\mathcal{H}} \) and nondegenerate closed two-form \( w^{\mathcal{H}} \). They turn, respectively, to a riemannian and a symplectic structure on the manifold \( \mathbb{P}\mathcal{H} \), with \( \mathcal{H} \) understood as a tangent space over \( \mathbb{P}\mathcal{H} \). The complex structure \( j^{\mathcal{H}} \) imposes the relationships

\[ g^{\mathcal{H}}(\xi, \zeta) = w^{\mathcal{H}}(\xi, j^{\mathcal{H}}\zeta), \]

(261)
\[ \nabla^{g^{\mathcal{H}}} j^{\mathcal{H}} = 0, \]

(262)
where \( \nabla^{g^{\mathcal{H}}} \) is a covariant derivative on \( \mathcal{H} \) associated with \( g^{\mathcal{H}} \). These two equations imply that the triple \((g^{\mathcal{H}}, w^{\mathcal{H}}, j^{\mathcal{H}})\) equips \( \mathcal{H} \) in the structure of the Kähler manifold. If \( \mathcal{H} \cong \mathbb{C}^{n+1} \) and some orthonormal basis \( \{e_a\} \) in \( \mathcal{H} \) is chosen, \( a \in \{0, \ldots, n\} \), then the inner product on \( \mathcal{H} \) can be denoted (using abstract index notation)

\[ \langle \zeta, \zeta \rangle_{\mathcal{H}} = \varepsilon^a_{\ z} \varepsilon^a_{\ 0}, \]

(263)
while the infinitesimal equations for riemannian metric \( g^{\mathcal{H}} \) and symplectic form \( w^{\mathcal{H}} \) read

\[ ds^2 = g_{ab} d\zeta^a \otimes d\zeta^b, \]

(264)
\[ w^{\mathcal{H}} = w_{ab} d\zeta^a \wedge d\zeta^b. \]

(265)
The projection of these structures to the projective space \( \mathbb{P}\mathcal{H} \), provided in finite-dimensional case by \( z^0 := \zeta^a/\zeta^0, \ a \in \{1, \ldots, n\} \), induces a metric \( ds^2_{\mathbb{P}\mathcal{H}} \) and a \( U(1) \) connection one-form \( A_{\mathbb{P}\mathcal{H}} \),

\[ ds^2_{\mathbb{P}\mathcal{H}} := \frac{1}{1 + z^a z_a}, \]

(266)
\[ A_{\mathbb{P}\mathcal{H}} := i z^a d\zeta_a. \]

(267)
The space \( \mathbb{P}\mathcal{H} \) has the structure of the compact Kähler manifold, the metric \( ds^2_{\mathbb{P}\mathcal{H}} \) is the Fubini–Study metric, while the connection one-form \( A_{\mathbb{P}\mathcal{H}} \) is the Berry connection. In finite dimensional case,

\[ \mathcal{H} \cong \mathbb{C}^{n+1} \Rightarrow \mathbb{P}\mathcal{H} \cong \mathbb{C}\mathbb{P}^n \cong S^{2n+1}/U(1), \]

(268)
while the Fubini–Study metric on \( \mathbb{P}\mathcal{H} \) is given explicitly by

\[ g^{\text{FS}}_{ab} = \frac{\langle \zeta, \zeta \rangle_{\mathcal{H}} \delta_{ab} - \zeta(a) \zeta^b}{|\langle \zeta, \zeta \rangle_{\mathcal{H}}|^2}, \]

(269)
where the round brackets denote the symmetrisation of indices. The space \( \mathbb{C}\mathbb{P}^n \) has a symmetry group of dimension \( n(n + 2) \), which is generated by a family of \( n(n + 2) \) Killing vector fields.

This framework allows a geometric description and reconsideration of the structure of the Hilbert space based framework of quantum theory. In particular, the self-adjoint operators on \( \mathcal{H} \), generating the unitary Schrödinger evolutions on \( \mathcal{H} \), correspond to such smooth functions on the Kähler manifolds \( \mathbb{P}\mathcal{H} \) that preserve the Kähler structure (that is, their hamiltonian vector fields are also the Killing vector fields). These hamiltonian functions on \( \mathbb{P}\mathcal{H} \) are given by the normalised expectations \( \langle \zeta, H\zeta \rangle_{\mathcal{H}} / \langle \zeta, \zeta \rangle_{\mathcal{H}} \) of the corresponding self-adjoint operators \( H \) on \( \mathcal{H} \). Moreover, the geodesic distance \( d_{g^{\text{FS}}} \) with respect to the Fubini–Study metric determines the transition probability between two vectors,

\[ p(\xi|\zeta) = \langle \zeta, \zeta \rangle_{\mathcal{H}}, \]

(270)
thus

\[ d_{g^{\text{FS}}} (\zeta, \xi) = \arccos (\text{tr}_{\mathcal{H}} (P_\zeta P_\xi)), \]

(271)
where $P_\xi$ and $P_\zeta$ are projection operators on the 1-dimensional subspaces of $\mathcal{H}$ that are linearly spanned by $\xi$ and $\zeta$, respectively.

An interesting additional geometric structure can be introduced using the coherent vectors representation. Let there be given a group $G$ together with its irreducible unitary representation $G \ni g \mapsto U(g) \in \mathcal{B}(\mathcal{H})$. Then, for a given choice of a normalised reference vector $\zeta \in \mathcal{H}$ (specified, for example, as the vector invariant under the maximal compact subgroup of $G$), one can define the Hilbert space vectors $U(g)\zeta \in \mathcal{H}$, introduce the equivalence relation

$$g_1 \sim g_2 \iff \exists e^{i\lambda} \in \mathbb{C} \quad U(g_1)\zeta = e^{i\lambda}U(g_2)\zeta,$$

(272)

and define the homogenous quotient space $\Gamma := G/\sim$. The space $\Gamma$ is a parameter space that defines and labels the coherent vectors of $\mathcal{H}$ by $[308, 116, 268, 269]$

$$\iota_\Gamma : \Gamma \ni z \mapsto U(z)\zeta \in \mathbb{P}\mathcal{H}.$$

(273)

Using $\iota_\Gamma$, one can pullback the geometric objects from $\mathbb{P}\mathcal{H}$ to $\Gamma$, equipping $\Gamma$ with the symplectic, riemannian and affine structure:

$$\mathbf{d}s^2_\Gamma := \|\mathbf{d}z\|^2 - \langle\mathbf{d}z, \mathbf{d}z\rangle = \|\mathbf{d}z, \mathbf{d}z\| = \|\langle z, \mathbf{d}z\rangle\|^2,$$

(274)

$$A_\Gamma := i\langle z, \mathbf{d}z\rangle,$$

(275)

$$\omega_\Gamma := \mathbf{d}A_\Gamma,$$

(276)

where $\mathbf{d}$ denotes the exterior derivative on $\Gamma$, and $\omega_\Gamma$ is a symplectic structure on $\Gamma$ if it is nondegenerate. If the space $\Gamma$ is interpreted as the ‘phase space’, then $\iota_\Gamma$ is interpreted as a map from ‘phase space’ to ‘space of rays’.

Anastopoulos and Savvidou [13] have used these results in order to uncover the relationship between the quantum histories and the metric structure on the projective Hilbert space. Using coherent vectors $z \in \mathcal{H}$, they derive

$$\langle z, z + \delta z \rangle = 1 + \langle z, \hat{c}_a z^a \rangle_{\mathcal{H}} \delta z^a + \frac{1}{2} \langle z, \hat{c}_a \hat{c}_b z^a \rangle_{\mathcal{H}} \delta z^a \delta z^b + O(\delta z^3)$$

(277)

$$= \exp \left( iA_a(z + \frac{1}{2} \delta z^a \delta z^b - \frac{1}{2} \mathbf{g}^{FS}_{ab} \delta z^a \delta z^b + O(\delta z^3) \right).$$

(278)

For $\delta z_k = z_{k+1} - z_k$, the equation (248), written in the form

$$\delta z_{H=0}(P_w, P_\theta) = \prod_k \langle z_k, z_k + \delta z_k \rangle_{\mathcal{H}},$$

(279)

leads to second-order approximation

$$\delta z_{H=0}(P_w, P_\theta) = \exp \left( i \sum_k (z_k + \frac{1}{2} \delta z_k) \delta z_k - \frac{1}{2} \sum_k \delta z_k^2 \right).$$

(280)

If the paths $z(\cdot)$ are continuous and the variations $\delta z_k$ are bounded ($|\delta z_k^a| < \epsilon$ and $\epsilon \to 0$), then this equation converges to the expression (243) on the geometric phase. However, if the paths $z(\cdot)$ cannot be considered as continuous (or differentiable) functions of $t$, then the approximation of the histories functional for the cut-off of the scale of $t$ given by $\frac{1}{t}$ leads to [13]

$$\delta z_{H=0}(P_w, P_\theta) = \exp \left( i \int_{\gamma} {A_\Gamma} - \frac{1}{2v} \int_{\gamma} \mathbf{d}t \mathbf{g}^{FS}_{ab}(z(t)) z^a z^b \right).$$

(281)

This result is very closely related to the Daubechies–Klauder approach [77, 194, 195, 198], who introduced exact continuous-time regularised coherent vectors propagator for the phase space path integral,
and proved that under mild assumptions on Hamiltonian (square and quadric integrability, see e.g. [197] for a brief statement of those) one has

$$\langle z(t = s), e^{-iHs}z(t = 0) \rangle_{H} = \lim_{v \to +\infty} \int \mathcal{D}z(\cdot) e^{\left(i \int_{0}^{s} \delta z(t) \right)} e^{-\frac{1}{\hbar} \int_{0}^{s} g_{ab}(z(t)) \dot{z}^{a} \dot{z}^{b}}$$

$$= 2\pi \lim_{v \to +\infty} e^{v\hbar/2} \int \tilde{\mu}_{W}(p_{\Gamma}, q_{\Gamma}) e^{i\int (p_{r} dq_{r} - H(p_{r}, q_{r}) dt)},$$

where $h(z(t))$ is a Hamiltonian function$^{32}$ on $\Gamma$, while $\tilde{\mu}_{W}(p_{\Gamma}, q_{\Gamma})$ is a pinned Wiener measure on a phase space $\Gamma$. Moreover, this formulation is covariant under canonical transformations of phase space coordinates, while nothing forbids us from applying it to other inequivalent ones. The above result shows that the metric structure on the Hilbert space (and Hilbert space, and there is provided no procedure solving the problem of choice of unique description be canonically equivalent on the level of phase space become unitarily inequivalent on the level of the coordinates, what makes these prescriptions incomplete, because descriptions which are considered to be inequivalent ones. The above result shows that the metric structure on the Hilbert space (and the corresponding metric structure on $\Gamma$) provides an important conceptual and mathematical element of the quantum theory.

It is also interesting to note that for finite value of $v$ the propagator (282) is not longer unitary [195]. From the perspective of histories approach to quantum theory, this means that the metric structure on the Hilbert space allows (some sort of) quantification of the nonunitary (and noncontinuous) temporal behaviour. This observation should be furnished by an additional result of Klauder and Maraner [199], who showed that the usual definition of dynamics on phase space by means of Hamilton’s variational principle,

$$\delta \int dt (\theta_{a} \dot{\xi}^{a} - h(\xi(t))) = 0,$$

where $\omega_{ab} = \partial_{a} \theta_{b} - \partial_{b} \theta_{a}$ is a symplectic form on the phase space, while $\xi$ are arbitrary phase space coordinates, is equivalent to the variational principle

$$\delta \int dt (\theta_{a} \dot{\xi}^{a} + \frac{1}{2} \lambda g_{FS}^{ab}(\xi(t)) \dot{\xi}^{a} \dot{\xi}^{b}) = 0$$

under constraint

$$\det (g_{FS}^{ab}(\xi)) = h^{-2n}(\xi)$$

and in the limit $\lambda \to 0$, where $g_{FS}^{ab}(\xi)$ is a riemannian metric on the phase space, $2n$ is the dimension of this space, while $\lambda \in \mathbb{R}$ is an arbitrary scale factor. This result was derived in the context of phase space $\Gamma$, but nothing forbids us from applying it to $\mathbb{P} \mathcal{H}$, with the Hamiltonian function provided by normalised expectation of Hamiltonian operator and with the riemannian metric provided by the Fubini–Study metric of $\mathbb{P} \mathcal{H}$. The equation (286) takes then the form of variation of the equation (255),

$$\delta \langle S^y(\xi(\cdot)) \rangle = \delta \int_{t_{0}}^{t_{n}} dt \langle \dot{\xi}(t), \left( i \frac{d}{dt} - H \right) \xi(t) \rangle_{H} = 0,$$

$^{32}$In the context of our paper, we consider it to be defined by $h(z(t)) := \langle z(t), Hz(t) \rangle_{W}$ for a given self-adjoint Hamiltonian operator $H$ on $\mathcal{H}$.

57
which gives the Schrödinger equation. This leads to a question whether some modification of the variational principle (287) on $\mathcal{PH}$ could result in an interesting form of the temporal behaviour of quantum theoretic models? In particular, it seems that for not vanishing metric term, provided by the finite values of $\lambda$ corresponding to finite values of $v$ in (281) and (282), the resulting temporal behaviour would be nonunitary.

These observations will play an important guiding role in generalisation of the elements of histories approach to an algebraic context.

### 4.5 Case study: Algebraic action operator and the limits of unitarity

Given a $W^*$-algebra $\mathcal{N}$ and $\psi \in \mathcal{W}_0(\mathcal{N})$, consider a crossed product $\mathcal{N} \rtimes_{\sigma^\psi} \mathbb{R}$, defined as the von Neumann algebra acting on the Hilbert space $L_2(\mathbb{R}, dt; \mathcal{H}) \cong \mathcal{H} \otimes L_2(\mathbb{R}, dt)$ and generated by the operators $\pi_{\sigma^\psi}(x)$ and $u_R(t)$, which are defined by

\[
(\pi_{\sigma^\psi}(x)\xi)(t) := \sigma^\psi_t(x)\xi(t), \quad (u_R(t_2)\xi)(t_1) := \xi(t_1 - t_2),
\]

for all $x \in \mathcal{N}$, $t_1, t_2 \in \mathbb{R}$, $\xi \in L_2(\mathbb{R}, dt; \mathcal{H})$, see e.g. [355]. These two operators satisfy the covariance equation

\[
u_R(t)\pi_{\sigma^\psi} \circ \pi_{\sigma^\psi}(x)\nu_R(t) = \pi_{\sigma^\psi}(\sigma^\psi_t(x)).
\]

The equation (290) can be written as

\[
(\pi_{\sigma^\psi}(x)\xi)(t) = \Delta^t_{\psi}x\Delta^{-it}_{\psi}\xi(t) = e^{-iK_{\psi}t}xe^{iK_{\psi}t}\xi(t),
\]

where $K_{\psi}$ is a modular hamiltonian of the modular operator $\Delta_{\psi}$. So, the covariance equation (292) translates between the family of unitaries that partially generate the crossed product algebra $\mathcal{N} \rtimes_{\sigma^\psi} \mathbb{R}$ and the modular automorphism of the underlying von Neumann algebra $\mathcal{N}$:

\[
u_R(t)\pi_{\sigma^\psi} \circ \pi_{\sigma^\psi}(x)\nu_R(t)^* = \pi_{\sigma^\psi}(e^{-itK_{\psi}}xe^{itK_{\psi}}).
\]

Using the uniqueness of the standard representation up to unitary equivalence, Falcone and Takesaki [99] (see [210] for a pedagogical introduction) proved that the map $\mathcal{N} \mapsto \mathcal{N} \rtimes_{\sigma^\psi} \mathbb{R}$ extends to a functor $\text{VNCore}$ from the category $\text{VNIso}$ of von Neumann algebras with $*$-isomorphisms to its own subcategory $\text{VN}_d\text{Iso}$ of semi-finite von Neumann algebras with $*$-isomorphisms. The functoriality $\text{CanVN} : W^*\text{Iso} \rightarrow \text{VN}_d\text{Iso}$ of Kosaki’s construction [203] of canonical representation $\pi_{\mathcal{C}}$ of any $W^*$-algebra $\mathcal{C}$ turns the assignment

\[
\mathcal{C} \mapsto \pi_{\mathcal{C}}(\mathcal{C}) =: \mathcal{N} \mapsto \mathcal{\hat{N}} = \overline{\pi_{\mathcal{C}}(\mathcal{C})}
\]

to a functor

\[
W^*\text{Core} : W^*\text{Iso} \rightarrow \text{VN}_d\text{Iso},
\]

where $W^*\text{Core} \circ \text{CanVN}$, while $W^*\text{Iso}$ consists of $W^*$-algebras and $*$-isomorphisms. For any $W^*$-algebra $\mathcal{N}$, the object $W^*\text{Core}(\mathcal{N}) \in \text{Ob}(\text{VN}_d\text{Iso})$ will be called canonical core of $\mathcal{N}$ and denoted $\mathcal{\hat{N}}$. By equipping the canonical core von Neumann algebra $\mathcal{\hat{N}}$ of the countably finite $W^*$-algebra $\mathcal{N}$ with the choice of some $\omega \in \mathcal{\hat{N}}_{\omega_0}$, we obtain a unitary isomorphism $\mathcal{\hat{N}} \cong \mathcal{N} \rtimes_{\sigma^\omega} \mathbb{R}$.

The operator $\nu_R(t)$, when considered as an operator on $L_2(\mathbb{R}, dt)$, takes the form

\[
u_R(t) = e^{-i\mathcal{V}}, \quad \mathcal{V} := -\frac{d}{dt}.
\]

So, the analogue of a quantum ‘histories liouvillean’ automorphism (241) is naturally present in the structure of a unitary representation of the canonical core algebra. From the covariance equation (292) it follows that this automorphism of $\mathcal{N} \rtimes_{\sigma^\omega} \mathbb{R}$ uniquely corresponds to the modular automorphism of $\mathcal{N}$. Hence, the pair $(\mathcal{N}, \omega)$ uniquely determine a $W^*$-dynamical system $(\mathcal{N}, \mathbb{R}, \sigma^\omega)$. But there might be also given another description of a temporal behaviour related with the same algebra $\mathcal{N}$, provided
by some group of \(\ast\)-automorphisms \(\alpha : \mathbb{R} \to \text{Aut}(\mathcal{N})\). If \(\alpha\) is continuous in the weak-\(\ast\) topology, then one has to consider the coexistence of two \(W^{\ast}\)-dynamical systems: \((\mathcal{N}, \mathbb{R}, \sigma^\omega)\) and \((\mathcal{N}, \mathbb{R}, \alpha)\). While \(\sigma^\omega\) is completely determined by the properties of \(\mathcal{N}\) and \(\omega\), the \(\ast\)-automorphism \(\alpha\) is arbitrary. Using familiar terminology, one can say that \(\sigma^\omega\) is a ‘kinematic’ automorphism, while \(\alpha\) is a ‘causal’ automorphism. These characteristics of \(\sigma^\omega\) and \(\alpha\), together with an equation (297) lead us to propose to consider \(\sigma^\omega\) as an algebraic replacement of the ‘histories liouvillean’ automorphism (233) and to consider \(\alpha\) as an algebraic replacement of the ‘histories hamiltonian’ automorphism (234). We will join these two separated automorphisms into one automorphism, representing the ‘complete temporal behaviour’ of the quantum theoretic model \((\mathcal{N}, \alpha, \omega)\), and forming an algebraic replacement for the ‘histories action’ automorphism (235).

We do not require the model \((\mathcal{N}, \alpha, \omega)\) to be a ‘quantum dynamical system’ (in the sense of [273]) with respect to \(\alpha : \mathbb{R} \to \text{Aut}(\mathcal{N})\), because we do not need to (and do not want to) assume the invariance of \(\omega\) with respect to \(\alpha\). In fact, instead of declaring invariance of \(\omega\) with respect to \(\alpha\), we will use \(\alpha\) in order to construct a new algebraic state \(\phi\). Consideration of the derivations of these \(\ast\)-automorphisms together with the corresponding hamiltonians is also not useful here, because of the lack of a unique characterisation of unbounded generators of \(\ast\)-automorphisms in terms of corresponding self-adjoint hamiltonians (see [210] for more discussion and further references on this).

The standard liouvillean of \(\sigma^\omega\) is given by its modular hamiltonian \(K_\omega = -\log \Delta_\omega\). We will denote by \(L_\alpha\) the standard liouvillean of \(\alpha\) in the GNS representation \((\mathcal{H}_\omega, \pi_\omega, \Omega_\omega)\). If

\[
L_{\alpha,\omega} := L_\alpha + K_\omega + J_\omega K_\omega J_\omega
\]

is essentially self-adjoint on \(\text{dom}(K_\omega) \cap \text{dom}(L_\alpha) \cap \text{dom}(J_\omega K_\omega J_\omega)\), and if \(K_\omega + L_\alpha\) is essentially self-adjoint on \(\text{dom}(K_\omega) \cap \text{dom}(L_\alpha)\), then

\[
u_{\alpha,\omega}(x)(t) := e^{it(K_\omega + L_\alpha)}xe^{-it(K_\omega + L_\alpha)} \quad \forall x \in \pi_\omega(\mathcal{N}),
\]

is a weak-\(\ast\) continuous \(\ast\)-automorphism of \(\pi_\omega(\mathcal{N})\), and \(L_{\alpha,\omega}\) is its standard liouvillean. Hence, \((\pi_\omega(\mathcal{N}), \mathbb{R}, \nu_{\alpha,\omega})\) is a \(W^{\ast}\)-dynamical system with a corresponding crossed product \(\pi_\omega(\mathcal{N}) \rtimes_{\nu_{\alpha,\omega}} \mathbb{R}\). Moreover, if \(L_\alpha\) is bounded, then the DFFA convergent perturbation expansions hold:

\[
u_{\alpha,\omega}(x) = \sum_{n=0}^{\infty} i^n \int_{0 \leq t_1 \leq \cdots \leq t_n \leq t} dt_1 \cdots dt_n [\alpha_{t_n}(K_\omega), \ldots, [\alpha_{t_1}(K_\omega), \alpha_t(x)] \ldots],
\]

\[
E_{\alpha,K_\omega}(t) := e^{it(K_\omega + L_\alpha)}e^{-itL_\alpha} = \sum_{n=0}^{\infty} i^n \int_{0 \leq t_1 \leq \cdots \leq t_n \leq t} dt_1 \cdots dt_n \alpha_{t_n}(K_\omega) \cdots \alpha_{t_1}(K_\omega).
\]

Hence, under some relatively weak conditions, the modular automorphism \(\sigma^\omega\) and the additional \(\ast\)-automorphism \(\alpha\) form together a unique automorphism \(\nu_{\alpha,\omega}\) with its own self-adjoint liouvillean \(L_{\alpha,\omega}\). If one thinks of \(\alpha\) as an algebraic analogue of an automorphism generated by the ‘interaction hamiltonian’, then the automorphism \(u_{\alpha,\omega}\) can be considered as a ‘correction’ of \(u_\omega\) by means of an associated \(U(1)\) connection 1-form \([K_\omega, \cdot]\) on the Hilbert bundle of Hilbert spaces \(\mathcal{H}_\omega\) over the image of real line \(\mathbb{R}\) in \(\mathcal{M}(\mathcal{N})\). Given \(L_\alpha\) and \(K_\omega\), we can define also the operator

\[
L_{\omega,\alpha} := K_\omega + L_\alpha + J_\omega L_\alpha J_\omega,
\]

with the conditions on essential self-adjointness analogous to the case of \(L_{\alpha,\omega}\). This operator is not interpretable as a standard liouvillean of \(\alpha\) perturbed by a \(U(1)\) connection form. However, as we will see below, it also encodes some very interesting information.

By an analogy with the Hilbert space based histories approach to quantum theory we will call \(L_{\alpha,\omega}\) an (algebraic) action operator and will call \(u_{\alpha,\omega}\) an (algebraic) action automorphism. We will call \(L_{\omega,\alpha}\) a dual action operator.

Recall that in the Hilbert space based histories approach the action operator was a generator of a complete unitary temporal behaviour of a given quantum theoretic model, including not only
the ‘internal’ temporal unitary changes related to the fixed Hilbert space, but also the ‘external’
temporal unitary changes between two different Hilbert spaces (in fact, that formalism was limited to
the continuous one-parameter family of identical copies of the same Hilbert space). In the algebraic
approach, the change of a Hilbert space corresponds to the change of an algebraic state, and it implies
the corresponding change of a representation of an underlying W*-algebra. In order to strengthen
the relationship between the Hilbert space based histories and our algebraic approach, we will show
how the action operator is related to the change between two representations or between two different
algebraic states.

In order to do this, we need to use one more result of Dereziński, Jakšić and Pillet [80]. They
show that if \( \omega \) is a faithful Kubo–Martin–Schwinger state with respect to a \(*\)-automorphism \( u \) with
a parameter \( \beta \), then under the assumptions used previously for derivation of \(*\)-automorphism \( u^Q \)
and its standard liouvillean \( L_Q \), and assuming additionally that \( \left| e^{-\beta Q/2\Omega_\omega} \right|_{\mathcal{H}_\omega} < \infty \),

\[
\Omega_Q := e^{-\beta(L_u+Q)/2}\Omega_\omega, \\
\omega_Q(\cdot) := \langle \Omega_Q, \Omega_Q\rangle/\|\Omega_Q\|^2_{\mathcal{H}_\omega}
\]

satisfy

0) \( \Omega_\omega \in \text{dom}(e^{-\beta(L_u+Q)/2}) \),
1) \( \Omega_Q \in \mathcal{H}_\omega^* \) is cyclic and separating for \( \pi_\omega(\mathcal{N}) \),
2) \( \omega_Q \) is KMS with respect to \( u^Q \) and \( \beta \),
3) \( \log \Delta_{\Omega_Q} = -\beta L_Q \) and

\[
\log \Delta_{\Omega_Q,\Omega_L} = -\beta \Delta - \beta Q.
\]

By the Takesaki theorem, the faithful state \( \omega \) on a W*-algebra is always KMS with respect to \( \sigma^\omega \)
with \( \beta = 1 \). Hence, under the assumptions allowing for the construction of the dual algebraic action
operator \( L_{\omega,\alpha} \), and assuming also that \( \left| e^{-(K_\omega+L_\alpha)/2\Omega_\omega} \right|_{\mathcal{H}_\omega} < \infty \), it holds that

\[
\phi(\cdot) := \frac{\langle e^{-(K_\omega+L_\alpha)/2\Omega_\omega}, (\cdot)e^{-(K_\omega+L_\alpha)/2\Omega_\omega}\rangle_{\mathcal{H}_\omega}}{\left| e^{-(K_\omega+L_\alpha)/2\Omega_\omega} \right|_{\mathcal{H}_\omega}^2}
\]

is KMS with respect to \( u_{\omega,\alpha} \) with \( \beta = 1 \). Hence, \( u_{\omega,\alpha} \) is a modular automorphism of \( \pi_\omega(\mathcal{N}) \) with
respect to \( \phi \). This is a very interesting result, because it means that while (\( u_{\alpha,\omega}, L_{\alpha,\omega} \)) play the role of
an action automorphism and an action operator with respect to the pair \( (\mathcal{N}, \omega) \), \( (u_{\omega,\alpha}, L_{\omega,\alpha}) \) play the
role of a modular automorphism and a modular hamiltonian with respect to the pair \( (\mathcal{N}, \phi) \). Hence,
der under the assumptions

1. \( \omega \) is a faithful normal algebraic state on a W*-algebra \( \mathcal{N} \),
2. \( L_\alpha \) is a standard liouvillean of \(*\)-automorphism \( \alpha \) of \( \mathcal{N} \) affiliated with \( \pi_\omega(\mathcal{N}) \),
3. \( K_\omega + L_\alpha \) is essentially self-adjoint on \( \text{dom}(K_\omega) \cap \text{dom}(L_\alpha) \),
4. \( K_\omega + L_\alpha - J_\omega L_\alpha J_\omega \) is essentially self-adjoint on \( \text{dom}(K_\omega) \cap \text{dom}(L_\alpha) \cap \text{dom}(J_\omega L_\alpha J_\omega) \),
5. \( \left| e^{-(K_\omega+L_\alpha)/2\Omega_\omega} \right|_{\mathcal{H}_\omega} < \infty \),

the \(*\)-automorphism \( \alpha \) can be always assimilated as a part of the modular automorphism \( \sigma^\phi \) that is
uniquely specified by an ‘updated’ algebraic state \( \phi \) (306). In other words, the \(*\)-automorphism forming
a ‘causal’ part of an algebraic quantum action automorphism can be considered as a constitutive
element of a ‘kinematic’ temporal behaviour, just with respect to another algebraic state.

This way Savvidou’s construction of the Liouville and action operators acting on the symmetric
Fock–Cook Hilbert space \( \mathfrak{F}[\mathcal{H}] \) and generating two corresponding types of unitary temporal evolution
becomes replaced by the algebraic construction of liouvilllean and action operators generating the \(*\)-automorphisms of corresponding representations of canonical core W*-algebra \(\mathcal{N}\). The main structures of each approach, the Fock–Cook Hilbert space \(\mathfrak{F}[\mathcal{H}]\) and the Falcone–Takesaki W*-algebra \(\mathcal{N}\), are constructed in a functorial way from the corresponding underlying ingredients of the given quantum theoretic model: the Hilbert space \(\mathcal{H}\) and the W*-algebra \(\mathcal{N}\), respectively (for a functorial description of Fock space construction see e.g. [34]). Both approaches show that every quantum theoretic model is generically equipped with two different types of unitary temporal evolution: the ‘kinematic’ automorphism and the ‘causal’ automorphism. Moreover, while the particular quantitative form of the latter evolution can be arbitrarily postulated, the quantitative form of the former is determined by the particular (quantitative) representation of an abstract algebra that is used in the given model. Both approaches enable to incorporate these two different unitary temporal evolutions into a single unifying unitary ‘action’ evolution. Both approaches enable also to describe the generators of the ‘kinematic’ and ‘action’ evolutions in terms of operators acting on the ‘temporal’ space \(L_2(\mathbb{R}, dt)\). In the case of the Hilbert space based approach, all these automorphisms are generated by the corresponding hamiltonian operators, while in the case of algebraic approach the quantitative representations of all these automorphisms are generated by the corresponding standard liouvilllean operators.

However, apart from these similarities, there are also important differences between those two approaches. In particular, the representation of the histories algebra on the Fock–Cook space is unique, up to unitary equivalence, only for hamiltonians which have a form specified by the Araki theorem [14]. For a general hamiltonian there is no possibility to guarantee the uniquenes (up to unitary equivalence) of the Fock–Cook representation of the histories algebra of the Fock–Cook Hilbert space \(\mathfrak{F}[\mathcal{H}]\). In contrast to this, the representation of a core algebra \(\mathcal{N}\times_{\sigma^R} \mathbb{R}\) acting on \(H_\omega \otimes L_2(\mathbb{R}, dt)\) is uniquely determined, up to unitary equivalence, by any particular choice of a state \(\omega \in \mathcal{N}_4^+\), which is considered as part of the definition of the model. Moreover, while in both approaches the initial ‘dynamic’ unitary automorphism can be postulated as an arbitrary additional component of the model, only in the algebraic approach can the resulting (dual) ‘action’ automorphism be considered as purely ‘kinematic’ (modular) automorphism, related to the change of the algebraic state. The change of unitary description of the temporal behaviour of the quantum theoretic model \((\mathcal{N}, \omega)\) equipped with an additional ‘unitary’ \(*\)-automorphism \(\alpha\) is completely determined by the quantum theoretic model \((\mathcal{N}, \omega)\) and the map \(\omega \mapsto \phi\), which can be considered as a part of the definition of the model. There is no corresponding result of such type in the Hilbert space based approach to quantum histories. We consider these two results as an important suggestion in favour of the change of perspective on the role of unitary temporal behaviour of quantum theoretic models. Stating it briefly, instead of postulating the hamiltonian as an independent component of quantum theoretic model and later perturbing it (what seems to be the only method within the frames of the Hilbert space based approach to mathematical foundations of quantum theory), an algebraic approach allows to derive the liouvilllean that characterises the unitary temporal behaviour, given the information about change of state. The change between two identical quantitative Hilbert spaces equipped with the same quantitative representation of the operator algebra becomes replaced by the change between two different (but faithful) algebraic states which correspond to two different (but unitarily equivalent) quantitative representations.

In the similar way as in Savvidou’s Hilbert space based formulation: 1) when the generators of ‘kinematic’ and ‘causal’ automorphisms are joined into the new ‘action’ generator \(K_\omega + L_\alpha\), the reference to two different temporal parametrisations of \(\alpha\) and \(\sigma^\omega\) disappears (the choice of rescaling of the time parameter between \(\alpha_t\) and \(\sigma^\omega_s\) was implicitly set above to be \(t = s\), however any scalar relationship \(t = \lambda s, \lambda \in \mathbb{R}\), will work, and any of such choices corresponds to the choice of a specific section of a \(U(1)\) bundle for the \(-[\log \Delta_\omega, \cdot]\) connection); 2) the resulting description of temporal behaviour is an unitary automorphism which does not possess any explicit relationship with the von Neumann–Lüders nonunitary type of temporal behaviour. In consequence, the above construction is insufficient to deal with the problem of algebraic reformulation of the Anastopoulos–Savvidou histories description of the geometric phase. It seems that the idea of construction of localised unitary evolution without taking into account more specific information about the changes of local geometry of quantum
state spaces is just not enough.

In particular, the restriction of description of temporal behaviour of quantum models to \(*\)-automorphisms implies the preservation of spectrum: if \(\alpha\) is a \(*\)-automorphism of a C*-algebra \(\mathcal{C}\), then

\[
\alpha((z\mathbb{I} - x)^{-1}) = (z\mathbb{I} - \alpha(x))^{-1} \quad \forall x \in \mathcal{C} \forall z \in \mathbb{C}.
\]

The decision that description of temporal behaviour of quantum theoretic models should be provided in terms of the \(*\)-automorphisms removes a priori the possibility to describe the changes of the eigenvalues in time. This restriction is imposed by the ‘spectral principle’ which is a part of an idealistic ontological interpretation of a quantum theoretic formalism. However, it is too strong for many practical purposes.\(^{33}\) We do not see any reasons for accepting this situation other than wish of securing the validity of some very particular interpretation.\(^{34}\) In order to develop the framework which bypasses the double standards of dealing with description of experimental information and temporal behaviour, one has to consider the nonunitary description of temporal behaviour as a valid constituent of the structure of quantum theoretic models. The nonunitary changes of quantitative representation can be determined in an algebraic approach by nonunitary changes of algebraic states. Hence, in order to provide such nonunitary description, one has to introduce some method of ‘updating’ the algebraic state that corresponds to a specified information.

Note that in the current Section we can replace the use of a standard liouvillean of a global W*-dynamical system \((\mathcal{N}, \mathbb{R}, \alpha)\) by a local quantum Poisson system \((\mathcal{M}(\mathcal{N}, \mathcal{B}), h)\), using the perturbations of a local liouvillean \(\pi_\omega(\mathcal{D}_p^\omega h)\) by \(K_\omega\) (and, dually, \(K_\omega\) by \(\pi_\omega(\mathcal{D}_q^\omega h)\)). This localises the linearity of a flow to a tangent space, allowing for a nonlinear generating function for the ‘causal’ part of the dynamics. As a result, the above discussion can be applied to local action operator and its dual. Yet, the localisation does not change the qualitative conclusions drawn from the above discussion, so we have chosen to keep the presentation in maybe a bit more familiar global language. Because \(\mathcal{B}\) is a Banach Lie algebra and \(\mathcal{M}(\mathcal{N}, \mathcal{B})\) is constructed as a Banach Lie–Poisson submanifold, locally the generators of causal dynamics will be always linear, so will be the flow determined by the Lie–Poisson bracket \(\{\cdot, \cdot\}\).

Hence, in order to get nonlinear contributions to the effective dynamics, some other geometric structure, beyond \(\pi_\omega(\mathcal{D}_p^\omega h)\) and \(K_\omega\), has to be used. In particular, from the discussion in Section 2.4.3 it follows that, given a bundle of the GNS Hilbert spaces over a trajectory of faithful normal states, a natural parallel transport operator is given by the standard unitary equivalence \(V_{\phi,\psi}\). The corresponding connection \(\nabla^{1/2}\) is a Levi-Civita connection of the Wigner–Yanase riemannian metric, and the local geodesic ‘free fall’ along \(\nabla^{1/2}\) corresponds to a norm projection in the (standard representation) Hilbert space, associated to a local continuous-time projective measurement. In this sense, the connection \(\nabla^{1/2}\) locally implements this what was an original intention of the nonhamiltonian part of the histories functional, as exposed by the equations (247), (248), (252), and (253). In a discussion of Savvidou’s action operator in Section 4.3 we have noticed that it does not restore this aspect of histories functional. Because the above algebraic action operator provides an exact algebraic generalisation of Savvidou’s formulation, it shares the same feature. One can think of Savvidou’s ‘Liouville’ operator \(V\) and modular hamiltonian \(K_\omega\) as generators of ‘intrinsic’ kinematic automorphisms of, respectively, a single Hilbert space \(\mathcal{H}\) or a single W*-algebra \(\mathcal{N}\). These should be taken into account when one provides a spatial representation of the ‘intrinsic’ causal automorphism of \(\mathcal{H}\) or \(\mathcal{N}\), respectively, in terms of a bundle of copies of \(\mathcal{H}\) or \(\mathcal{N}\) over a real line \(\mathbb{R}\). However, neither \(e^{iVt}\) or \(\sigma^\omega\) can be understood as representing the changes between quantitatively distinct Hilbert spaces, corresponding to different

\(^{33}\)In consequence, the range of applicability of the ‘unitary’ framework is usually extended by the use of additional mathematical tools and techniques, like parameter fitting or renormalisation, which are explicitly nonunitary, but are not considered as part of the content of the quantum theoretic model.

\(^{34}\)According to this interpretation, the eigenvalues of operators can be specified with infinite precision (at least in principle) by the quantitative results of experimental procedures, hence they have ontological meaning, and correspond to the ‘possessed properties’ of ontological quantum systems, as opposed to ‘postulated properties’ of ‘quantum theoretic models’. Unfortunately, this idealistic ontological interpretation does not apply to any actual experimental situation without additional techniques of processing of the quantitative results of experimental procedures which render the fundamental assumption of this interpretation false (or at least meaningless).
measurements. In case of the Hilbert space based histories, this change requires to use the Berry connection, while in the algebraic framework (as implemented systematically in Sections 2.5 and 3) this requires to use the connection $\nabla^{1/2}$, corresponding to the parallel transport operator $V_{\phi,\psi}$.

### 4.6 $W^*$-geometric quantum histories

In [211, 139] we showed that the nonunitary change of quantum states due to Lüders’ rule (and other rules, see also [245]) is a special case of the constrained minimisation of the quantum relative entropy functional $D_\rho$. Moreover, the local smooth geometry of the quantum models can be derived (under mild conditions) as the subsequent terms of the Taylor expansion of any smooth information distance $D$. This leads to the idea [205, 206, 208] to use quantum relative entropy as a general tool of generating nonunitary evolution of quantum states that takes into account the geometric structure of the quantum model.

Taking into account the above discussion, we consider the connection $\nabla^{D_\rho}$ derived from a Brègman distance $D_\rho$ to be the appropriate replacement for the Berry connection used in the Anastopoulos–Savvidou analysis, as well as for our own use of $K_\omega$ above. However, we are unfortunately lacking the mathematical structure that would allow us to practically use other connection then $\nabla^{1/2}$, thus below we will consider only this possibility. On the other hand, the affine Killing hamiltonian vector field used in Sections 4.3 and 4.4 can be replaced by an arbitrary hamiltonian function $h$ on $\mathcal{M}(\mathcal{N})$, provided the latter is equipped with a BLP manifold structure. Those two substitutions allow us to state the $W^*$-geometric versions of the formulas (246) and (255). On the differential geometric level (and ignoring for a moment a functional analytic incompatibility between BLP, GNS, and quantum information geometric manifold structures), the effective dynamics is described by the 1-form

$$\mathcal{F} = dh(\phi) - d\nabla^{1/2}(\phi),$$

where $d\nabla^{1/2}$ is a connection form of the Levi-Civita connection $\nabla^{1/2}$. This formula states that local causal dynamics and local inferential dynamics participate to the same extent in the effective local dynamics. Hence, neither inference nor causality is considered as more fundamental. The form $\mathcal{F}$ can be considered as a localisation of the causal inference instrument (3) that does not impose the ordering on composition of causal and inferential dynamics.

In order to generalise the additional regularising riemannian term in (281) and (282), let us consider the expansions

$$D(\phi + \varepsilon v, \phi) = \frac{\varepsilon^2}{2} g^{ab}(\phi) v^a v^b + \mathcal{O}(\varepsilon^3)$$

and [290]

$$D_\gamma(\phi + \varepsilon v, \phi) = \frac{\varepsilon^2}{2} g^{ab}(\phi) v^a v^b + \frac{\varepsilon^3}{6} (\nabla^0 + \nabla^2) v^a v^b v^c + \mathcal{O}(\varepsilon^4),$$

where $\nabla^{ab}$ are the Christoffel symbols of the corresponding connections. Setting $\varepsilon^2 = \frac{1}{k}$ suggests us to use the quantity

$$P_{k,1,1}^{\gamma,e} := e^{-k \int dt D(\phi(t) + \varepsilon \frac{d\phi(t)}{dt}, \phi(t)) \sqrt{\det(g^D)}}$$

as a generalised regulariser, where $k \in \mathbb{R}^+$ is a constant. We interpret this object as a local quantum entropic prior: an expression for a local prior measure representing user’s ignorance about the choice of propagation between neighbouring states along a specific trajectory $\gamma : [0, s] \to \mathcal{M}(\mathcal{N})$. See Section 4.7 for a discussion of entropic priors in the commutative case. More specifically, (311) is a localised quantum version of the $P_{k,1,1}$ prior. For $D_{1/2}(\sigma, \rho) = \frac{1}{2} \left| \sqrt{\sigma} - \sqrt{\rho} \right|^2_\mathcal{H}$, this corresponds to integrating against a local gaussian measure. The global Jeffreys prior $\sqrt{\det(g^{D_{1/2}})}$ appears already in the Klauder–Maraner formula (287), as a constant (288), which sets a relationship between local measure of uncertainty of inference and local generator of causal dynamics.

---

35 As opposed to $K_\omega$, $V_{\phi,\psi}$ cannot be used in the perturbation of the standard liouvillean, because it is a mapping between two different standard representations, not an operator acting on a single Hilbert space.
Thus, we propose to generalise the formula (282) to

\[
\lim_{\varepsilon \to +0} \int D\phi(t) e^{i \int_0^T dt \langle \Omega_0(t) \mathbf{A} \phi_1(t) \Omega_0(t) \rangle_{\mathcal{H}(t)} - i \int_0^T dt \langle \Omega_0(t) \pi_0(t) \Omega_0(t) \rangle_{\mathcal{H}(t)} + e^{-k \int dt D(\phi(t) + \varepsilon \frac{d\phi(t)}{dt}) \sqrt{\det(g^D)}}.}
\]

As discussed in Section 1.2, there are some legitimate reasons to believe that at least at the level of the second order approximation of an entropic prior, the above formula can receive an exact foundation by means of stochastic integration process. Yet, without a proof of this conjecture, the formula (312) has now a status of a heuristic proposal. However, most of the applications of path integrals in theoretical physics have precisely the same status (the exactness of the Daubechies-Klauder formula (282) is more an exception than a rule).

The differences between the formulas (312) and (189) correspond to the standard differences between algebraic and path integral formulations. Both formulations admit introducing additional local gauge and source terms, so they can be used to study various applied models. Taking a closer look at the Daubechies-Klauder formula (282), one may note that the left side of this equation is formulated without taking into consideration the possible changes of the GNS representation along the states, because the coherent vector states are considered to be defined in a single Hilbert space. If such changes would be considered (as we do it here), then an operator \(e^{-\varepsilon H_s}\) in (282) should be multiplied from left by a corresponding standard unitary transition operator. This leads us to the conjecture:

\[(189) = (312),\]

if the left hand side of this equation is evaluated in terms of the MCP, instead of the GNS, Hilbert space. While this conjecture is quite heuristic, it seems to be a legitimate candidate for a W*-geometric analogue of the Daubechies-Klauder propagator formula (282). A development of a suitable stochastic calculus allowing for an exact mathematical treatment of (312), as well as the proof that the proposed construction of MCP Hilbert space is well defined, are the necessary conditions to approach the problem of proving this conjecture. Yet, in Section 5.3, we will propose another, more geometric approach to the equivalence intended behind the formula (313), without requiring equality on the level of Hilbert bundles.

4.7 Appendix: Entropic priors on statistical models

To simplify the notation, whenever we will use the coordinate-dependent formulas in this Section, we will assume that the statistical model \(M := M(\mathcal{X}, \mathcal{G}(\mathcal{X}), \mu) \subseteq L_1(\mathcal{X}, \mathcal{G}(\mathcal{X}), \mu)^+\) is equipped with a global coordinate system \(\Theta : \mathcal{X} \to M\), where \(\Theta \subseteq \mathbb{R}^n\) is open.

The entropic prior \(P_{k,\alpha,\beta}\) is defined in order to provide the general «statistical representation of the [notion of the] vacuum of information in a given hypothesis space» [289]. Every probability measure encodes some knowledge, hence the notion of the ‘vacuum of information’ has also to refer to some given knowledge which defines it. The ‘vacuum of information’ is relative to the given information manifold, and as such it is defined to depend on the invariant volume measure on the information manifold, the Jeffreys prior [180]

\[J(\theta) = \sqrt{|\det g(\theta)|} d\theta_1 \wedge \ldots \wedge \theta_n,\]

which distributes prior probability over all hypothesis space, as well as on the initial reference density \(p_0(x, \theta) = p_0(x|\theta)P(\theta)\) on \(\mathcal{X} \times \Theta\) which sums up all additional reference knowledge (e.g., the quantitative results of previous experimental procedures) which will be encoded into the structure of the vacuum of information.

In particular, when the reference knowledge consists only of model-independent information encoded in the density \(m(x)\), then the reference density factorises to \(p_0(x, \theta) = m(x)P(\theta)\). The entropic prior build with respect to such factorisation encodes the ‘vacuum of information’ regarding the dependence between the parameters \(\Theta\) of the model \(M\) and the initial knowledge \(m(x)\) about the data \(\mathcal{X}\).
In the nonparametric formulation based on $D_\gamma$ entropies for $\gamma \in [0, 1]$, the entropic prior is defined as such $P_{k,\alpha,\beta}$ which minimises the functional [290]

$$\inf_P (k \int P(p) D_\alpha(p, p_0) + D_\beta(P, J)),$$

where $(\alpha, \beta) \in [0, 1] \times [0, 1]$, the distance $D_\alpha$ is calculated over $X \times \Theta$, the distance $D_\beta$ is calculated over $\Theta$, and the scalar $k \geq 0$ parametrises the preference of $P$ over $J$ with respect to the reference density $p_0$. In the parametric formulation of the functional minimised in (315) reads

$$kD_\alpha(p(x)\theta)P(\theta), p_0(x|\theta)P(\theta)) + D_\beta(P(\theta), \sqrt{\det g(\theta)}d\theta).$$

By definition, the entropic priors are minimisers of the estimation by expected loss (decision) functional $D_\alpha$ under the constraint that the $D_\beta$-distance of entropic prior $P$ from volume measure $J$ does not exceed some constant value. In other words, they express the degree of confidence in the reference distribution, relatively to degree of confidence in volume measure invariance of $P$.

The general solution of the above minimisation problem takes the form

$$P_{k,\alpha,\beta} = \tilde{P}_{k,\alpha,\beta} J,$$

where $\tilde{P}_{k,\alpha,\beta}(\theta)$ is a scalar density which, up to normalisation, is equal to [290, 329, 330]

$$\tilde{P}_{k,\alpha,\beta}(\theta) := \left\{ \begin{array}{ll} 1 + k(1 - \beta)D_\alpha(p_0, p_0) - \frac{1}{\beta} & : \beta \neq 1, \\ \exp(-kD_\alpha(p_0, p_0)) & : \beta = 1, \end{array} \right.$$

under the condition that

$$k_{\text{min}} := \inf\{ k \geq 0 \mid \int P_{k,\alpha,\beta} < \infty \}$$

exists and $k \geq k_{\text{min}}$. If $k_{\text{min}} = 0$, then $P_{0,\alpha,\beta}$ is Jeffreys prior. On the other hand, $P_{0,\alpha,\beta}$ is the Dirac delta concentrated on $p_0$. Moreover, $\tilde{P}_{k,\alpha \in [0,1], \beta \in [0,1]}$ is a multivariate Student t distribution, $\tilde{P}_{k,\alpha,0}$ is a generalised multivariate Cauchy distribution, $\tilde{P}_{k,\alpha,1}$ is a minimum $D_\alpha$ prior density, and

$$\tilde{P}_{k,1,1}(p) = e^{-kD_1(p, p_0)}$$

is a maximum relative entropy (= minimum $D_1$ distance) prior density. If $p_0$ is taken to be the Bernoulli–Laplace uniform prior, then $\tilde{P}_{1,1,1}(p) = e^{-S_{\text{CS}}(p)}$ is a maximum Gibbs–Shannon entropy density (Jaynes prior [166]). A maximum Gibbs–Shannon entropy density can be also recovered as $\tilde{P}_{x, 1,1}(p)$ if $p_0$ is an element of the exponential family. When no reference distribution (no background information) is specified, then $\tilde{P}_{k,\alpha,\beta}$ reduces trivially to Jeffreys’ prior. If the reference measure $p_0$ does not belong to a manifold $Q$ on which the minimisation procedure generating the entropic prior is evaluated, then $k(1 - \beta)$ factor for $\beta \neq 1$ is replaced by a more general scalar quantity $\kappa$, dependent on the projection of $p_0$ on $Q$ (for details, see [329]).

If $p_0$ is a maximum entropy distribution obtained under some given constraints, then the entropic prior quantifies to what extent the densities other than $p_0$ (within a given model) are less probable or less reliable. The reliability of $p(x|\theta)$ other than $p_0(x|\theta)$ decreases exponentially with the deviation of $p(x|\theta)$ from $p_0(x|\theta)$, and the sensitivity for this exponential decrease is controlled by the constant $k$.

In general, the larger $k$ is, the stronger is the impact of reference distribution (assumed background information) on the inference provided with respect to the ‘vacuum of information’ $P(\theta)$. If the reference hypothesis is built up from knowledge independent of the model (encoded in $m(x)$), then the larger $k$ is, the more preference is given to this independent knowledge. On the other hand, the smaller $k$ is, the more inference based on $P(\theta)$ will depend on distributions other than $p_0(x|\theta)$, so it becomes easier for the eventual ‘noise’ in constraints to be taken by inference to be a ‘signal’. So, while $k \to 0$ smoothens the prior, $k \to \infty$ sharpens it. Jeffreys’ and Jaynes’ (maximum Gibbs–Shannon entropy) priors are just two extreme points of this scale.

The entropic priors $\tilde{P}_{k,1,1}$ are the only entropic priors on probabilistic manifold which are based on the measure of distance which is coordinate invariant, local, consistent for independent subsystems and
additive. This is a characterisation of \( D_1 \) as a unique distance functional on the space of normalised probability densities used for the purpose of probability updating, as provided in [324, 325, 186]. Hence, they are the unique priors which encode the notion of coordinate invariant, local, additive, and independent subsystem consistent ‘vacuum of information’. For more discussion on the topic of entropic priors, see [328, 49, 51, 52, 288, 290, 331, 329].

5 Information theoretic renormalisation

In this section we will analyse another application of quantum information geometry for the purposes of inference over quantum models. We start from discussion of the Jaynes–Mitchell source theory [241, 173, 177, 118, 120], which describes the general continuous changes of information states of an exponential model driven by the sources of information. Next, we discuss Favretti’s [100] information geometric generalisation of this theory to the setting of dually flat information manifolds. It allows for a strictly geometric implementation of the idea of renormalisation of dynamics by reduction of dimensionality of the model by fixing the control parameter, which is provided on the space of information states (as opposed to the space of functions or operators). Our original contribution amounts to an observation that the Jaynes–Mitchell–Favretti approach is canonically related to the use of Brègman distances, so it can be used to locally approximate information dynamics on an arbitrary manifold of quantum states. We discuss how this setting allows to use the departure of local geometry from the dually flat smooth geometry (generated by quantum Brègman distances) as the geometric description of multiparameter nonlinear quantum control and renormalisation problems. We also introduce another type of geometric renormalisation of inferential dynamics of quantum states, which describes situations where none of specific control (covariate) parameter is fixed, but the quantum model is subjected to the action of completely positive maps. This procedure is based on the use of \( D_1 \) distances as well as associated contraction coefficients, introduced by Ruskai et al [72, 64, 293, 227].

5.1 Jaynes–Mitchell source theory

Consider first an arbitrary statistical model \( \mathcal{M}(\mathcal{A}) \) over finite boolean algebra\(^{36} \mathcal{A} \) (with \( m \in \mathbb{N} \) denoting the number of elements of \( \mathcal{A} \)), a set \( \{f_k\}_{k=1}^m \) of functions \( f_k : \mathcal{A} \rightarrow \mathbb{R} \) with \( n \in \mathbb{N} \), and a change in the expectation \( \langle f_k \rangle_p \), caused by the independent changes in both \( f_k(x_i) =: f_k \) and \( p(x_i) =: p_i \),

\[
\delta \langle f_k \rangle = \sum_{i=1}^m p_i \delta f_k^i + \sum_{i=1}^m \delta f_k^i p_i. \tag{321}
\]

If \( f_k \) depends on some additional parameters \( r = (r_1, \ldots, r_l) \), such that

\[
\delta f_k(x_i, r) = \sum_{j=1}^l \frac{\partial f_k(x_i, r)}{\partial r_j} \delta r_j, \tag{322}
\]

then the first term of (321) reads

\[
\sum_{i=1}^m p_i \delta f_k^i = \langle \delta f_k \rangle_p = \left\langle \sum_{j=1}^l \frac{\partial f_k(x_i, r)}{\partial r_j} \delta r_j \right\rangle_p =: \delta W_k. \tag{323}
\]

We denote the second term of (321) by \( \delta Q_k \), so

\[
\delta Q_k := \sum_{i=1}^m f_k^i \delta p_i = \delta \langle f_k \rangle_p - \langle \delta f_k \rangle_p, \tag{324}
\]

\(^{36}\)For the reasons of mathematical fanciness, we occasionally consider the sets \( \mathcal{M}(\mathcal{A}) \subseteq L_1(\mathcal{A})^+ \) of finite positive measures over localisable boolean algebras \( \mathcal{A} \), but this is completely equivalent to consideration of localisable measure spaces \( \mathcal{M}(\mathcal{X}, G(\mathcal{X}), \bar{\mu}) \subseteq L_1(\mathcal{X}, G(\mathcal{X}), \bar{\mu})^+ \).
which gives
\[
\delta \langle f_k \rangle_p = \delta W_k + \delta Q_k.
\] (325)

Consider now an exponential family defined as an \( n \)-dimensional parametric probabilistic manifold [76, 202, 276]
\[
\mathcal{M}_\text{exp}(\mathcal{X}, \mathcal{U}(\mathcal{X}), \bar{\mu}) := \{ p(\chi, \theta) := \exp(-\log Z(\theta) - \sum_{i=1}^{n} \theta^i f_i(\chi)) \mid \theta := (\theta^1, \ldots, \theta^n) \in \Theta \subseteq \mathbb{R}^n \},
\] (326)
where \( f_i : \mathcal{X} \to \mathbb{R} \) are assumed to be arbitrary functions, linearly independent of each other and of the constant function 1 (this guarantees that \( \theta \mapsto p(\theta) \) is one-to-one and that the matrix \( g_{ij} \) is invertible [366]),
\[
\log Z(\theta) := \log \int_{\mathcal{X}} \bar{\mu}(\chi) \exp \left( - \sum_{i=1}^{n} \theta^i f_i(\chi) \right)
\] (327)
is a factor arising from normalisation condition \( \int_{\mathcal{X}} \bar{\mu}(\chi)p(\chi, \theta) = 1 \), called a Massieu functional [238, 239], while \( \Theta \subseteq \mathbb{R}^n \) is supposed to be such open set that the integral in (327) converges. The study of geometric properties of this family provided an original stimulus for development of information geometry [55, 59, 93, 6]. In particular, Chencov found [55, 57] that the finite dimensional exponential families are geodesic surfaces of \( \nabla^0 \)-connections and admit the generalised pythagorean equation (144) for the Kullback–Leibler distance.

If \( \text{dim} \mathcal{X} = m < \infty \), then \( \int_{\mathcal{X}} \bar{\mu}(\chi)k(\chi) = \sum_{j=1}^{m} k(\chi_j) \) for any \( k : \mathcal{X} \to \mathbb{R} \). In such case \( \mathcal{M}_\text{exp}(\mathcal{X}, \mathcal{U}(\mathcal{X}), \bar{\mu}) \) can be characterised in terms of the Gibbs–Jaynes [112, 166] procedure of maximisation of the Gibbs–Shannon entropy [112, 316, 317]
\[
S_{\text{GS}}(p) := -\sum_{j=1}^{m} p(\chi_j) \log p(\chi_j)
\] (328)
subject to constraints \( F(p) \) given by
\[
\left\{ \begin{array}{l}
\sum_{j=1}^{m} p(\chi_j)1 = 1, \\
\sum_{j=1}^{m} p(\chi_j)f_i(\chi_j) = \eta_i,
\end{array} \right.
\] (329)
with \( \eta := (\eta_i) \in \Xi \subseteq \mathbb{R}^n \). The maximum value attained by \( S_{\text{GS}} \) for a given \( (\eta_i) \) (or, equivalently, for a given \( (\theta^i) \)), reads
\[
S_{\text{GS}}(p(\theta)) = \log Z(\theta) + \sum_{i=1}^{n} \theta^i \eta_i.
\] (330)

If \( p \) belongs to an exponential family with \( \lambda_k := \theta^k \), \( k \in \{ 1, \ldots, n \} \), then the corresponding change in entropy reads
\[
\delta S_{\text{GS}} = \delta \log Z(\lambda) + \delta \left( \sum_{k=1}^{n} \lambda_k \langle f_k \rangle_p \right)
= \frac{1}{Z} \left( \sum_{k=1}^{n} \delta \lambda_k f_k^2 + \sum_{k=1}^{n} \lambda_k \delta f_k \right) e^{-\sum_{k=1}^{n} \lambda_k f_k} + \sum_{k=1}^{n} \delta \lambda_k \langle f_k \rangle_p + \sum_{k=1}^{n} \lambda_k \delta \langle f_k \rangle_p
= \sum_{k=1}^{n} \lambda_k (\delta \langle f_k \rangle_p - \langle \delta f_k \rangle_p) = \sum_{k=1}^{n} \lambda_k \delta Q_k.
\] (331)
Due to (322), \( \sum_{k=1}^{n} \lambda_k \delta Q_k(\langle f_k \rangle_p, r) \) is an exact differential of \( S_{\text{GS}}(\langle f_k \rangle_p, r) \), even if \( \delta Q_k(\langle f_k \rangle_p, r) \) is not an exact differential of any function. Thus, (331) is equivalent to
\[
\delta S_{\text{GS}} = \sum_{k=1}^{n} \lambda_k \delta \langle f_k \rangle_p - \sum_{k=1}^{n} \sum_{j=1}^{l} \lambda_k \left( \frac{\partial f_k}{\partial r_j} \right)_p \delta r_j
\] (332)
we consider a second source affects the relationship between first source and the response parameter? Following Mitchell and Jaynes, will now provide an answer to a question: how the presence of the functional \( x \mathcal{M} f \) where \( x \) is just a function of thermodynamics and hold for any exponential family. The first law of equilibrium thermodynamics is just a special case of the above result.

Let us now consider a three dimensional exponential family

\[
\mathcal{M}_{\text{exp}}(\mathcal{Y}, \mathcal{U}(\mathcal{X}), \mu; \Theta) := \left\{ p(\lambda A, \lambda B, \lambda C) = \frac{1}{Z} e^{-\lambda A f A(x) - \lambda B f B(x) - \lambda C f C(x)} \mid (\lambda A, \lambda B, \lambda C) \in \Theta \right\},
\]

where \( f_A, f_B, f_C \in L_\mathcal{X}(\mathcal{Y}, \mathcal{U}(\mathcal{X}), \mu) \), and \( \Theta \subseteq \mathbb{R}^3 \) is some fixed open set. Let the change of information be described by \( \langle f_A \rangle_p \rightarrow \langle f_A \rangle_p + \delta \langle f_A \rangle_p \) with the additional conditions that the possible changes of \( \langle f_B \rangle_p \) are left unconstrained (\( \delta \lambda B = 0 \) but we allow \( \delta \langle f_B \rangle_p \neq 0 \)), and it is known that \( \langle f_C \rangle_p \) does not change (\( \delta \langle f_C \rangle_p = 0 \) but we allow \( \delta \lambda C \neq 0 \)). The quantity \( \langle f_A \rangle_p \) is called a ‘driving variable’. Thus, we consider a source-and-response problem with an additional control variable:

\[
\delta \langle f_A \rangle = 0, \quad \delta \lambda A \neq 0 \quad \text{‘driving variable’ (source parameter)}
\]

\[
\delta \langle f_B \rangle \neq 0, \quad \delta \lambda B = 0 \quad \text{‘information heat bath’ (response parameter)}
\]

\[
\delta \langle f_C \rangle = 0, \quad \delta \lambda C \neq 0 \quad \text{‘control variable’ (additional source)}
\]

Following Mitchell and Jaynes, will now provide an answer to a question: how the presence of the second source affects the relationship between first source and the response parameter?

Given some finite dimensional statistical model \( \mathcal{M}(\mathcal{A}) \) parametrised by a coordinate system \( \lambda : \mathcal{M}(\mathcal{A}) \rightarrow U \subseteq \mathbb{R}^n \) with \( n := \text{dim}(\mathcal{M}(\mathcal{A})) \), then the general form of the variation of an expectation functional \( \langle f \rangle_p \) for some element \( p(\lambda_0) \in \mathcal{M}(\mathcal{A}) \) reads

\[
\delta \langle f \rangle_p := \langle f \rangle_{p(\lambda)} - \langle f \rangle_{p(\lambda_0)} = \sum_{i=1}^n \frac{1}{\lambda_0 (j_1, \ldots, j_n)} \frac{\partial^i \langle f \rangle_{p(\lambda)}}{\partial \lambda_{j_1} \cdots \partial \lambda_{j_n}} \mid \lambda = \lambda_0 \delta \lambda_{j_1} \cdots \delta \lambda_{j_n}.
\]

The first order term of (335) (corresponding to the linear character of variation) reads

\[
\delta \langle f \rangle_p = \sum_{j=1}^n \frac{\partial \langle f \rangle_p}{\partial \lambda_j} \delta \lambda_j.
\]

In the case of exponential model \( \mathcal{M}_{\text{exp}}(\mathcal{A}; \Theta) \), from the equations (336) and

\[
K_{ij} = \frac{\partial^2 \log Z(\lambda)}{\partial \theta^i \partial \theta^j} = - \frac{\partial \langle f_i \rangle_p}{\partial \lambda^j} = - \frac{\partial \langle f_i \rangle_p}{\partial \lambda^i},
\]

it follows that the relationship between ‘fluxes of information’ \( \delta \langle f_k \rangle_p \) and ‘forces of information’ \( -\delta \lambda_k \) can be determined in the first (linear) order by the covariance matrix

\[
\begin{pmatrix}
\delta \langle f_A \rangle_p \\
\delta \langle f_B \rangle_p \\
\delta \langle f_C \rangle_p
\end{pmatrix} = - \begin{pmatrix}
K_{AA} & K_{AB} & K_{AC} \\
K_{BA} & K_{BB} & K_{BC} \\
K_{CA} & K_{CB} & K_{CC}
\end{pmatrix} \begin{pmatrix}
\delta \lambda_A \\
\delta \lambda_B \\
\delta \lambda_C
\end{pmatrix}.
\]

\[\text{In this terminology } \lambda_k \text{ play the role of the ‘potentials of information’, but this should not be confused with the ‘scalar potentials’ } \Psi \text{ and } \Psi^T \text{ on hessian manifolds, such as } -\log Z(p) \text{ and } S_{GS}(p) \text{ (which play the role of information discrimination functionals).}\]
Hence,
\[ \delta \lambda_C = -\frac{K_{CA}}{K_{CC}} \delta \lambda_A, \tag{339} \]
which means that \( \delta \lambda_C \) and \( \delta \lambda_A \) are not independent of each other. This is also reflected in the second equation following from (338), namely
\[ \delta \langle f_A \rangle_p = -\delta \lambda_A \left( K_{AA} - \frac{K_{AC}^2}{K_{CC}} \right), \tag{340} \]
which is equivalent to
\[ \frac{\delta \langle f_A \rangle_p}{\delta \lambda_A} = \frac{\partial \langle f_A \rangle_p}{\partial \lambda_A} - \frac{K_{AC}^2}{K_{CC}}. \tag{341} \]
If we decide to consider only the variables \( \langle f_A \rangle_p \) and \( \langle f_B \rangle_p \) (removing \( \langle f_C \rangle_p \) from the definition of the problem), then the covariance matrix of the problem takes the form
\[ \begin{pmatrix} \delta \langle f_A \rangle_p \\ \delta \langle f_B \rangle_p \end{pmatrix} = - \begin{pmatrix} K_{AA} & K_{AB} \\ K_{BA} & K_{BB} \end{pmatrix} \begin{pmatrix} \delta \lambda_A \\ \delta \lambda_B \end{pmatrix}. \tag{342} \]
From the assumption that there are no additional parameters \( r \) of control associated with the element \( f_A \) of the abstract algebra (that is, \( \langle f_A \rangle_p = 0 \)), it follows that \( \delta \langle f_A \rangle_p = \delta Q_A \). In such case the above equation turns into
\[ \delta \langle f_B \rangle_p = \frac{K_{BA}}{K_{AA}} \delta Q_A. \tag{343} \]
Hence, the changes of \( \langle f_B \rangle_p \) are driven by the ‘source of information’ \( \delta Q_A \). We will call the corresponding evolution of probability distribution \( p(\lambda_A, \lambda_B, \lambda_C) \in \mathcal{M}_{\exp}(A; \Theta) \) an ‘information driving’. The number of different variables is not limited to three, but three variables are sufficient to describe all possible types of constraints. Mitchell [241] has shown that the readjustment of expectation values of functions \( \{ f_k \} \) under driving caused by sources of information can be described the following equivalent principles:

i) expectations uncorrelated with driven variables remain unchanged,

ii) Lagrange multipliers of unconstrained variables remain unchanged,

iii) SGS is re-maximised under new values of constraints.

Now we move to the problem of renormalisation of sources, which amounts to removing the variable \( C \) from the definition of the model, while keeping it as a constraint in the allowed transformations of variables (information flows). Consider again the covariance matrix (338), with the constraint \( \delta \langle f_C \rangle_p = 0 \). A direct calculation shows that the relationships between 'fluxes' and 'forces' of information related with \( A \) and \( B \) can be completely described by the covariance matrix
\[ \begin{pmatrix} \delta \langle f_A \rangle_p \\ \delta \langle f_B \rangle_p \end{pmatrix} = - \begin{pmatrix} \tilde{K}_{AA} & \tilde{K}_{AB} \\ \tilde{K}_{BA} & \tilde{K}_{BB} \end{pmatrix} \begin{pmatrix} \delta \lambda_A \\ \delta \lambda_B \end{pmatrix}, \tag{344} \]
where
\[ \begin{cases} 
\tilde{K}_{AA} := K_{AA} - K_{AC} K_{CC}^{-1} K_{CA} \\
\tilde{K}_{AB} := K_{AB} - K_{AC} K_{CC}^{-1} K_{CB} \\
\tilde{K}_{BA} := K_{BA} - K_{BC} K_{CC}^{-1} K_{CA} \\
\tilde{K}_{BB} := K_{BB} - K_{BC} K_{CC}^{-1} K_{CB}.
\end{cases} \tag{345} \]
The covariance matrix (344) can be thought of as a ‘renormalised’ version of the covariance matrix (342), where the dependence on an additional correlated information related to variable \( C \) is taken into account. Assuming again that \( \delta \lambda_B = 0 \) and \( \langle f_A \rangle_p = 0 \), the predicted change of \( \langle f_B \rangle_p \) due to the action of the source \( \delta Q_A \) takes the form
\[ \delta \langle f_B \rangle_p = \frac{\tilde{K}_{BA}}{\tilde{K}_{AA}} \delta Q_A = \left( \frac{K_{BA}}{K_{AA}} - \frac{K_{BC} K_{CA}}{K_{CC} K_{AA}} \right) \delta \hat{Q}_A, \tag{346} \]
where
\[
\delta Q_A := \frac{\delta Q_A}{(1 - R^2_{AC})}
\]
(347)
is the ‘renormalised information source strength’, while
\[
R_{AC} := \frac{K_{AC}}{(K_{AA} K_{CC})^{\frac{1}{2}}}
\]
(348)
is the correlation coefficient. In other words, the additional constraint \( \delta \langle f_C \rangle_p = 0 \) imposed on the information related to an additional variable that is correlated with the driving variable \( \langle f_A \rangle_p \) is observed in ‘renormalisation’ of the action of the driving source \( \delta Q_A \) on the dimensionally ‘reduced’ system of variables (without \( \langle f_C \rangle_p \)):
\[
\delta \langle f_B \rangle_p = \frac{K_{BA}}{K_{AA}} \frac{\delta Q_A}{1 - R^2_{AC}}.
\]
(349)
Now, if \( R_{AC} \) has a spectral radius smaller than 1, one can expand the renormalisation factor in (347) and (349),
\[
(1 - R^2_{AC})^{-1} = \sum_{n=0}^{\infty} (R^2_{AC})^n = 1 + R^2_{AC} + R^4_{AC} + \ldots.
\]
(350)
Defining the ‘propagators’ \( G_{ij} := -K_{ij} K_{jj}^{-1} \), one can expand (346) in the form
\[
\delta \langle f_B \rangle_p = (G_{BA} - G_{BC}G_C + G_{BA}G_AC - G_{BC}G_CA + G_{BA}G_CA - \ldots) \delta Q_A.
\]
(351)
Thus, the dimensional reduction of the information model which removes from the scope the correlated constrained variable changes the description of information flow, which can be recast in terms of perturbative series of propagators between the ‘sources’ of driving variables and ‘information fluxes’ of driven variables (‘sinks’) that are mediated by the “virtual” (removed) variable. Comparison of (336) with (335) leads us to note, following Jaynes, that the above effects appear at the first level of perturbative expansion in powers of information source strength. In consequence, the corresponding classification of approximated results is provided by the degree of fine tuning of the available information. This brings a clear meaning to the perturbative expansion and renormalisation as the process of classification of approximated description of the quantitative effects of change of information with respect to the degree of quantitative refinement of this information (which is given by information source strength). This approximation does not refer to any additional ‘theoretical’ or ‘physical’ dimensional constant parameters and keeps the values and meaning of the constants defining experimental response scales, etc., to be fixed by definition and not entering the scene. Thus, there is also no need for ‘renormalisation’ of these constants, avoiding the conceptual problems which are always caused by such procedure.

5.2 Favretti’s dually flat geometrisation

Now we turn to reformulation and generalisation of the Jaynes–Mitchell source theory provided by Favretti [100]. Suppose that \( \mathcal{M}(\mathcal{A}) \) is a probability manifold with \( \text{dim} \mathcal{M}(\mathcal{A}) = n \in \mathbb{N} \), equipped with the pair of coordinate systems \( (\theta, \eta) : \mathcal{M}(\mathcal{A}) \to \Theta \times \Xi \subseteq \mathbb{R}^n \times \mathbb{R}^n \). Let the information about trajectory \( p(t) \in \mathcal{M}(\mathcal{A}) \) be specified as the constraints expressed in terms of both coordinate systems:
\[
\begin{cases}
F_1(\theta(p), t) = 0, \\
F_2(\eta(p), t) = 0.
\end{cases}
\]
(352)
Favretti shows that under additional assumption that \( \mathcal{M}(\mathcal{A}) \) is equipped also with a riemannian metric \( g \) and a pair of affine connections \( (\nabla^\theta, \nabla^\eta) \) such that \( (\mathcal{M}(\mathcal{A}), g, \nabla^\theta, \nabla^\eta) \) is a dually flat manifold with a dually flat coordinate system given by \( (\theta, \eta) \) (see Section 2.4.1), the implicit function theorem allows
one to describe geometrically the evolution $p(t)$ quantitatively, in terms of one of these coordinate systems.

Let the scalar potential functions determined by the above dually flat geometry be denoted by $\Psi(\theta) := \Psi \circ \theta$ and $\Psi^k(\eta) := \Psi^k \circ \eta$, where $\Psi^k$ is a Fenchel dual of $\Psi$ with respect to (114). Consider the diagram

\[
\begin{array}{c}
\Xi \\
\downarrow \pi_A^\Xi \\
\Xi_A \\
\uparrow \pi_B^\Xi \\
\Theta_B \\
\end{array}
\]

\[
\Xi \xrightarrow{\pi_A^\Xi} \Xi_A \xleftarrow{\pi_B^\Xi} \Theta_B,
\]

where $L^{-1}_\Psi : \Xi \to \Theta$ and $L_\Psi : \Theta \to \Xi$ are the Legendre transforms given by smooth diffeomorphisms, which are expressed in coordinate-dependent way as

\[
\theta^i = (L^{-1}_\Psi(\eta))^i = \frac{\partial}{\partial \eta^i} \Psi^L(\eta) =: \partial^i \Psi^L(\eta),
\]

(354)

while

\[
\eta_k = (L_\Psi(\theta))_k = \frac{\partial}{\partial \theta^k} \Psi(\theta) =: \partial_k \Psi(\theta),
\]

(355)

are projections with

\[
\eta = (\eta_A, \eta_B) \in \mathbb{R}^k \times \mathbb{R}^{n-k},
\]

(356)

\[
\theta = (\theta^A, \theta^B) \in \mathbb{R}^k \times \mathbb{R}^{n-k}.
\]

(357)

The maps $\pi_A^\Xi$ and $\pi_B^\Theta$, when equipped with particular values at their codomain (denoted here, respectively, by $\bar{\eta}_A \in \Xi_A \subseteq \mathbb{R}^k$ and $\bar{\theta}^B \in \Theta_B \subseteq \mathbb{R}^{n-k}$), provide an example of the constraints (352):

\[
\left\{ \begin{array}{l}
\eta_A(p(t)) = \pi_A^\Xi(\eta(p(t))) = \bar{\eta}_A, \\
\theta^B(p(t)) = \pi_B^\Theta(\theta^B) = \bar{\theta}^B.
\end{array} \right.
\]

(360)

The subspaces $\Xi_A$ and $\Theta_B$ denote, respectively, the range of the values $\bar{\eta}_A$ and $\bar{\theta}^B$ of the constraints $\pi_A^\Xi$ and $\pi_B^\Theta$. The fibres corresponding to these projections are given by

\[
\mathcal{M}_\Xi(\bar{\eta}_A) := (\pi_A^\Xi)^{-1}(\bar{\eta}_A) = \{ \eta \in \Xi \mid \eta_A = \bar{\eta}_A \} \subseteq \Xi,
\]

(361)

\[
\mathcal{M}_\Theta(\bar{\theta}^B) := (\pi_B^\Theta)^{-1}(\bar{\theta}^B) = \{ \theta \in \Theta \mid \theta^B = \bar{\theta}^B \} \subseteq \Theta,
\]

(362)

and they induce the corresponding leaves of a pair of foliations of $\mathcal{M}(\mathcal{A})$ by

\[
\mathcal{M}(\bar{\eta}_A) := \{ p \in \mathcal{M}(\mathcal{A}) \mid (\pi_A^\Xi \circ \eta)(p) = \bar{\eta}_A \},
\]

(363)

\[
\mathcal{M}(\bar{\theta}^B) := \{ p \in \mathcal{M}(\mathcal{A}) \mid (\pi_B^\Theta \circ \theta)(p) = \bar{\theta}^B \},
\]

(364)

with

\[
\bigcup_{\bar{\theta}^B \in \Theta_B} \mathcal{M}(\bar{\theta}^B) = \mathcal{M}(\mathcal{A}) = \bigcup_{\bar{\eta}_A \in \Xi_A} \mathcal{M}(\bar{\eta}_A).
\]

(365)

Using the orthogonality (110) of the coordinate systems $\theta^i$ and $\eta_k$, Favretti shows that the tangent space at the point $p \in \mathcal{M}(\bar{\theta}^B) \cap \mathcal{M}(\bar{\eta}_A)$ has the following orthogonal decomposition

\[
T_p \mathcal{M}(\mathcal{A}) = T_p \mathcal{M}(\bar{\theta}^B) \oplus T_p \mathcal{M}(\bar{\eta}_A) = \text{span}\{e_1, \ldots, e_k\} \oplus \text{span}\{e^{k+1}, \ldots, e^n\}.
\]

(366)
For any $a \in \Xi_A$ and $b \in \Theta_B$, the leaves $\mathcal{M}(a)$ and $\mathcal{M}(b)$ are, respectively, $\nabla^\eta$- and $\nabla^\theta$- autoparallel submanifolds of $\mathcal{M}(\mathcal{A})$, hence they are called **mutually dual foliations**. Favretti observes that this allows to consider the evolution $t \mapsto p(t)$ geometrically, as a horizontal lift with respect to an integrable Ehresmann connection.

Let us now assume that $\mathcal{M}(\mathcal{A})$ is an $(n+m)$-dimensional dually flat probability manifold equipped with the projections (356)-(359), as well as with an additional projection generated by

$$\pi^\Xi_C : \Xi \ni \eta \mapsto \eta_C \in \Xi_C \subseteq \mathbb{R}^m,$$

(367)

where $\eta = (\eta_A, \eta_B, \eta_C) \in \mathbb{R}^k \times \mathbb{R}^{n-k} \times \mathbb{R}^m$. One can introduce the foliation $\mathcal{M}(\tilde{\eta}_C)$, corresponding to the constraint $\eta_A - \tilde{\eta}_A = 0$, in the same way as before. In such case the pairs of mutually dual foliations are given by $\mathcal{M}(\tilde{\eta}_A, \tilde{\eta}_C)$, $\mathcal{M}(\tilde{\theta}^B)$ and $\mathcal{M}(\tilde{\eta}_C)$, $\mathcal{M}(\tilde{\theta}^A, \tilde{\theta}^B)$. However, $\mathcal{M}(\tilde{\eta}_C), \mathcal{M}(\tilde{\theta}^B)$ are not mutually dual.

This setting allows for the geometric generalisation of the source renormalisation procedure in the following form. Let temporal evolution $t \mapsto p(t)$ satisfy the constraints $\theta^B(t) = \tilde{\theta}^B$ and $\eta_C(t) = \tilde{\eta}_C$, that is,

$$\begin{cases}
\theta^B(p(t)) = (\pi^\theta_B \circ \theta)(p(t)) - \tilde{\theta}^B = 0, \\
\eta_C(p(t)) = (\pi^\eta_C \circ \eta)(p(t)) - \tilde{\eta}_C = 0,
\end{cases}$$

(368)

then

$$p(t) \in \mathcal{M}(\tilde{\theta}^B) \cap \mathcal{M}(\tilde{\eta}_C).$$

(369)

These conditions rephrase the Jaynes–Mitchell conditions $\delta \lambda_B = 0$ and $\delta \langle f_C \rangle = 0$ in the information geometric terms. Now one can find what is the form of evolution determined by these constraints, if changes of information are specified by the temporally driven ‘response’ parameters $\eta_A = \eta_A(t)$ (which corresponds to the ‘driving variable’ $\langle f_A \rangle$). The constraints (368) on the evolution can be restated using (354) in the form

$$\dot{\theta}^B \Psi^L(\eta_A(t), \eta_B(t), \tilde{\eta}_C) - \tilde{\theta}^B = 0.$$

(370)

Favretti has shown that the implicit function theorem applied to (370) implies the existence of a smooth map

$$h : \Xi_A \times \Xi_C \ni (\eta_A, \eta_C) \mapsto \eta_B \in \mathbb{R}^{n-k}$$

(371)

such that

$$\eta_B(t) = h(\eta_A(t), \tilde{\eta}_C),$$

(372)

$$\hat{\eta}_B(t) = \tilde{\theta}^A h(\eta_A(t), \tilde{\eta}_C) \dot{\eta}_A(t),$$

(373)

$$h(\eta_A(t), \tilde{\eta}_C) = -\left( (\tilde{\theta}^B \tilde{\theta}^B \Psi^L)^{-1} \tilde{\theta}^A \tilde{\theta}^B \Psi^L \right)|_{\eta_B = h(\eta_A(t), \tilde{\eta}_C)}.$$

(374)

By the assumption of dual flatness, this gives also

$$\dot{\eta}_B(t) = (\tilde{\Psi}_{,BA}(\tilde{\Psi}_{,AA})^{-1})|_{\theta = \tilde{\theta}} \dot{\eta}_A(t) =: \tilde{\Delta}_{BA}(\theta) \dot{\eta}_A(t),$$

(375)

where

$$\left( \Psi^L \right)^{ij} := \tilde{\delta}^i \tilde{\delta}^j \Psi^L = \frac{\partial^2 \Psi^L(\eta)}{\partial \eta_i \partial \eta_j} = g^{ij}(\eta),$$

(376)

$$\Psi_{,ij} := \tilde{\delta}_i \tilde{\delta}_j \Psi = \frac{\partial^2 \Psi(\theta)}{\partial \theta^i \partial \theta^j} = g_{ij}(\theta),$$

(377)

and

$$\tilde{\theta} := L^{-1}_{\Psi} (\eta_A, h(\eta_A(t), \tilde{\eta}_C), \tilde{\eta}_C),$$

(378)

$$
\tilde{\Psi}_{,BA} := \Psi_{,BA} - \Psi_{,BC}(\Psi_{,CC})^{-1} \Psi_{,CA},$$

(379)

$$\tilde{\Psi}_{,AA} := \Psi_{,AA}(1 - R_{AC}^2),$$

(380)

$$R_{AC}^2 := (\Psi_{,AA})^{-1} \Psi_{,AC}(\Psi_{,CC})^{-1} \Psi_{,CA}.$$

(381)
The equation (375) can be written more explicitly as

\[ \frac{\mathrm{d}\eta_B(p(t))}{\mathrm{d}t} = \mathbf{g}_{BA}(p(t)) \frac{1}{1 - R_{AC}^2(p(t))} \left( \mathbf{g}_{AA}(p(t)) \right)^{-1} \mathrm{d}\eta_A(p(t)). \]  

(382)

From (380) it follows that

\[ (\Psi_{,AA})^{-1} = \left( \mathbf{I} - R_{AC}^2 \right)^{-1} (\Psi_{,AA})^{-1}, \]

(383)

hence, if \( R_{AC} \) has a spectral radius smaller than 1, one can use (350), which leads to the perturbative expansion in terms of corrections that come from interaction with the additional source,

\[ \tilde{\mathbf{G}}_{BA} = \tilde{\mathbf{G}}_{BA}(\mathbf{I} - R_{AC}^2)^{-1} (\Psi_{,AA})^{-1} = \mathbf{G}_{BA} - \mathbf{G}_{BC} \mathbf{G}_{CA} + \mathbf{G}_{BA} \mathbf{G}_{AC} \mathbf{G}_{CA} + \ldots, \]

(384)

where

\[ \mathbf{G}_{ij} := \Psi_{,ij} (\Psi_{,jj})^{-1} \]

(385)

For \( \mathrm{d}\eta_B = \dot{\eta}_B(t) \mathrm{d}t \), \( \mathrm{d}\eta_A = \dot{\eta}_A(t) \mathrm{d}t \), the above expression takes the form

\[ \frac{\mathrm{d}\eta_B}{\mathrm{d}t} = (\mathbf{G}_{BA} - \mathbf{G}_{BC} \mathbf{G}_{CA} + \mathbf{G}_{BA} \mathbf{G}_{AC} \mathbf{G}_{CA} - \ldots) \mathrm{d}\eta_A, \]

(386)

which is a generalisation of (351). Hence, the additional constraint \( \mathrm{d}\eta_C = 0 \) acts as a source of information, which imposes nontrivial corrections in the relationship between the evolution of \( \mathrm{d}\eta_A \) and \( \mathrm{d}\eta_B \), that are perturbatively described by equation (386). Note that the implicit function theorem does not provide an explicit form of the function \( h \). Thus, one may need to integrate the equation (373). The equation (386) provides a perturbative approximation of (373), which can be subjected to integration. This might be called a ‘perturbative renormalisation’ or ‘inferential scattering’ of \( \mathbf{G}_{BA} \).

### 5.3 Brègman distance and nonlinear quantum control

An important feature of the Jaynes–Mitchell theory is that it allows to consider not only the ‘source’ (‘input’, ‘configuration’) and ‘response’ (‘output’, ‘registration’) variables, but also the ‘control’ (‘covariate’) variables, defined as fixed parameters of the model. The constraints imposed by these fixed variables can be factored out from the relationship between causes and effects, but at the price of ‘renormalisation’ of the source terms. It amounts to reduction of the dimensionality of the model (removing the dimensions described by control parameters) and subsequent rescaling of the remaining source terms by the ‘renormalisation factors’. Thus, one can eliminate control parameter from the model construction at the price of renormalisation of the source terms that determine the information dynamics. This procedure is nonperturbative and geometric, but under certain conditions it can be expanded in the perturbative series of corrections. Quite remarkably, the renormalisation factor that appears at the first order of expansion in powers of source strength can be perturbatively expanded in an infinite series of corrections, which contain all orders of interaction effects with the ‘virtual’ source terms that can be associated with the factored-out ‘control’ variables.\(^{38}\)

Besides generalisation from exponential families to dually flat manifolds, the information geometric framework introduces important conceptual change: the ‘source’, ‘response’, and ‘control’ variables are no longer associated with particular functions on the sample space, but rather with the particular coordinate variables on the information model. As discussed in Section 1.1, all these variables form specific examples of observables in our approach to quantum foundations. As a consequence, renormalisation of sources can be considered exactly as a transformation of information models that amounts to ‘coarse graining’ and subsequent rescaling. The coarse graining provides a reduction of dimension of the model that is preserving the operational definitions of the coordinate variables on a submodel, but at the price of redefinition of their functional relationship by means of change of the local geometry of the model from dually flat to curved one.

---

\(^{38}\)This phenomenon was first observed in the Heims–Jaynes analysis of the gyromagnetic effect [138], and appeared later also in Jaynes’ analysis of the Rayleigh acoustic scattering [173, 177] and (independently) in Schwinger’s source theory [309, 310].
In principle, the change of an information state $\phi \in \mathcal{M}(\mathcal{A})$ or $\phi \in \mathcal{M}(\mathcal{N})$, associated with an integrable real function $f$ over $\mathcal{A}$ or an operator $f \in \mathcal{N}^{sa}$, respectively, can be specified in three different ways: by means of $\delta(\phi(f))$, by means of $\phi(\delta f)$, or by means of a source term $\delta(\phi(f)) =: \delta Q_f$. The main insight of the source theory is that the changes specified by source terms have the direct operational meaning whenever the model $\mathcal{M}(\mathcal{A})$ is equipped with a pair of dually flat coordinate systems. In such case, the changes $(\delta \phi)(\cdot)$ can be reexpressed in terms of corresponding changes of source-and-response parameters. However, the change of information driven by the change of one of source-and-response variables leads to change of other variables that are correlated with it.

This can be interpreted as a cause-and-effect relationship, but under the condition that ‘causes’ and ‘effects’ are understood as inputs and outputs of correlation relationships, respectively. This is different from the meaning assigned to these terms in other sections of this work. In general, there are possible at least two clearly distinct perspectives on what the ‘causes’ and ‘effects’ are. From the purely operational perspective, any reproducible relationship between configuration and response parameters of description of experimental situation deserves to be called a causal relationship, and any predictively verifiable inferential procedure relating them is considered as a satisfying method of the theoretical modelling of causality (see e.g. [144]). On the other hand, from the ontologically flavoured perspective, the ‘causes’, ‘effects’, and their relationships are theoretical notions, which may indirectly correspond to epistemic parameters and predictively verifiable relationships between them, derived from some inductive procedure (see e.g. [266]). In this Section we chose the former terminology (speaking of ‘epistemic causality’, because the term ‘inferential causality’ would probably cause, nomen omen, more confusion), while in the rest of this work we consider causality and inference as a priori independent theoretical constructs, but without attribution of any ontological claims. From the inferential perspective, ‘causes’ are just the same as ‘configurations’.

If one of the parameter spaces $\{\Theta, \Xi\}$ can be considered as a space of ‘causes’ (‘configurations’), the other becoming a space of ‘effects’ (‘registrations’). The role of the Legendre transform $\mathbf{L}_\Psi : \Theta \to \Xi$ is to associate effects with causes (and vice versa). This allows to use $\mathbf{L}_\Psi$ (and “epistemic” ‘cause-and-effect’ interpretation) in order to analyse changes of effects following (correlatively, inferentially) from the changes of causes, as well as changes of causes following from the changes of effects. These two issues are known, respectively, as forward and backward induction problems. Let us also note that the dually flat geometry always satisfies the relationships (354) and (355) as well as (376) and (377). Hence, it also satisfies

$$\mathbf{g}_{ij}^\Psi(\theta) = \frac{\partial^2 \eta_i}{\partial \theta^j}. \tag{387}$$

The equations (355) and (387) assert that

- a Legendre transform $\mathbf{L}_\Psi$ governs the relationship between causes and effects,
- a riemannian metric $\mathbf{g}^\Psi$ governs the relationships between changes of causes and changes of effects.

From the perspective discussed in the Section 1.2.2, $\mathbf{L}_\Psi$ defines the ‘system of epistemic causality’ of an individual user (the perspective of a fixed measurement frame), relating the ‘configurations’ and ‘registrations’ in such way that the discrimination function on the space of configurations defines the discrimination function on the space of registration. On the other hand, $\mathbf{g}^\Psi$ defines the ‘local system of epistemic causality’ on the information manifold, allowing to translate between different local users. Hence, the source theoretic renormalisation can be interpreted as a perturbation of the local system of epistemic causality due to presence of the nonzero sources of information.

Now let us observe that, as discussed in Section 2.4.1, every dually flat manifold determines an associated Brègman distance $D_\Psi$. While our notation in Section 5.2 indicates this fact, it was left unnoticed by previous authors. Also, we note, following the discussion in Section 2.4.3, that the framework of dually flat manifolds and associated Brègman distances is applicable locally to any

Note that this notion of ‘causality’ belongs strictly to a theoretical layer of scientific inquiry. Without specification of some particular epistemic semantics it is not related in any specific way with the experimental ‘effects’ and ‘causes’.
quantum manifolds, as long as one defines the manifold structure using a specific Brègman function. The extension from commutative to quantum dually flat geometries is straightforward. The notation applied by us in Section 5.2 keeps the correct order of multiplications, so the quantities used in this Section can be interpreted as operators as well.

The equation (387) is a geometric equivalent of the linear case (336) of the expansion (335). In order to obtain higher-order terms of (335), one needs to consider information models that are not dually flat. Hence, one can in principle begin with an arbitrary quantum information model \(\mathcal{M}(\mathcal{N})\), equipped with a Brègman distance \(D_\Phi\) which defines the local ‘ideal’ dually flat manifold structure \((\mathcal{M}(\mathcal{N}), g^{D_\Phi}, \nabla^{D_\Phi}, (\nabla^{D_\Phi})^\dagger)\), and consider the emergence of the nonzero curvature of the effective riemannian geometry \((\mathcal{M}(\mathcal{N}), \tilde{g})\) as a result of presence of the additional source (control) terms that are ‘renormalised out’ by the transition \(g \to \tilde{g}\). It is quite interesting that the departure from the dually flat geometry and constant curvature of a model implies the presence of additional information sources operating at different points. From the perspective of analogy with general relativity, we can say that sources curve the geometry of a quantum information manifold. Combining this with our discussion of the role of quantum riemannian metric in the Daubechies–Klauder formula (see Sections (1.2.2) and (4.6)), we can conclude that the JMF renormalisation leads to the redefinition of the local prior measure used for the path integration. Interpreting the local prior measure as an information theoretic analogue of mass, we can say that this process encodes dependence on additional sources by the change of the geometry of a model, which is in turn reflected in the renormalisation of an information theoretic local mass, and a corresponding point-dependence of the zero-point energy.

We will use the term brègmanian renormalisation to refer to a local renormalisation of \((\mathcal{M}, D_\Phi)\) using JMF source theory. More generally, let us observe (following Lauritzen [223]), that the Norden–Sen geometry captures the description of information geometry only up to third order of Taylor series expansion of information distance, which in principle allows to develop higher–order differential tensor theories of information geometry, more general than the Norden–Sen geometry. Thus, it is plausible that the higher order source renormalisation terms may also possess a complete geometric representation, but requiring to use higher order tensor geometries arising from the Taylor expansion of the Brègman distance as the referential object subjected to renormalisation.

The ‘source term’ defined as above has different meaning than the ‘source term’ introduced in Section 3.2. Yet they are complementary. The former corresponds to a perturbation \(\delta \theta\) of a coordinate system \(\theta : \phi \to \theta(\phi) = \phi(x)\) under constraint \(\phi(\delta x) = 0\). This description rests on the assumption that all relevant local information which has to be taken under consideration is completely specified by means of the variations \(\delta \phi(x)\) and \((\delta \phi)(x)\). The latter corresponds to perturbation \(\delta x\) of an element \(x\) of a local GNS representation of a \(W^*\)-algebra \(\mathcal{N}\) by means of state dependent perturbation of liouvilean. Our approach allows \(\delta x\) to be arbitrary, so it can also depend on \(\phi\), and may not arise as an infinitesimal change generated by a global automorphism of \(\mathcal{N}\). These two different uses of a single notion are compatible and complementary in the sense provided by the equations (323)-(325): while the ‘sources’ of Sections 5.1 and 5.2 generalise the notion of ‘heat sources’, the ‘sources’ of Section 3.2 generalise the notion of ‘work sources’. In our work we view ‘work sources’ (respectively, ‘heat sources’) as the geometric perturbation of the geometry of causal evolution (respectively, inferential evolution).

### 5.4 Contraction coefficients

The Brègman renormalisation answers the question about the behaviour of the constraints of inference (and resulting information dynamics) under dimensional reduction of information model due to the presence of constant control parameters. However, given any information model and constraints of inference, there appears also another renormalisation-type question: what is the behaviour of these objects under coarse grainings? Because the constraints may involve information geometric quantities (for example, the ‘two point correlation function’ \(K_{xy}(\rho) = \int_0^1 d\lambda \text{tr}_\rho (\rho^\lambda x \rho^{1-\lambda} y)\) is an evaluation of the quantum Bogolyubov–Kubo–Mori riemannian metric \(g_{D_\rho}^f\) on the pair of tangent vectors \(x, y \in T_p\mathcal{M}(\mathcal{N})\)) this is related to the question about behaviour of information geometric quantities under completely positive maps. Restriction to quantum \(D_T\)-geometries, where \(f\) is an operator convex
function defining the $D_l$ distance, secures the Markov monotononcity of $g^{D_l}$ and $∇^{D_l}$, but this does not extend naturally to every geometric quantity on $\mathcal{M}(\mathcal{N})$ that can be built using these objects and their derivatives.

In the commutative case Chencov [58, 59] has defined the Markov monotone connections as such affine connections $∇^{D_l}$ that for any Markov map $T$ the image of a $∇^{D_l}$-geodesic line on $\mathcal{M}(\mathcal{A})$ belongs to a $∇^{D_l}$-geodesic line on $T_*(\mathcal{M}(\mathcal{A}))$ as its interval or its point, while an affine parameter of this line remains, up to rescaling, an affine parameter of the $∇^{D_l}$-geodesic line in the image [59]. Thus, the behaviour of any trajectory along a given $∇^{D_l}$-geodesic under the action of Markov maps is characterised by their invariance properties under coarse graining by preduals of Markov maps and rescaling by an affine parameter. This leads to a question whether it is possible to find a suitable analogue of an affine parameter for arbitrary quantum information model $\mathcal{M}(\mathcal{N})$ which would allow for some sort of control over the mutual behaviour of $\mathcal{M}(\mathcal{N})$, its information geometry, and information dynamics under coarse grainings. More specifically, we need to find some scalar contraction coefficient $η$, which globally characterises the geometry of $\mathcal{M}(\mathcal{N})$ and is Markov monotone, $η(\mathcal{M}(\mathcal{N})) \geq η(T_*(\mathcal{M}(\mathcal{N})))$, and then use it in order to rescale the constraints of inference on $\mathcal{M}(\mathcal{N})$. 

Some examples of contraction coefficients $η(T_*)$ were provided in the case when $\dim \mathcal{M}(\mathcal{N}) < \infty$, with semi-finite $\mathcal{N}$ by Lesniewski and Ruskai [227], following earlier works [72, 64, 293]:

$$η_{D_l}(T_*) := \sup_{\omega, \phi \in \mathcal{M}(\mathcal{N})} \left\{ \frac{D_l(T_*(\omega), T_*(\phi))}{D_l(\omega, \phi)} \right\}, \quad (388)$$

$$η_{g^{D_l}}(T_*) := \sup_{\phi \in \mathcal{M}(\mathcal{N})} \left\{ \sup_{u \in T_\phi \mathcal{M}(\mathcal{N})} \left\{ \frac{g^{D_l}(T_*(u), T_*(u))}{g^{D_l}_\phi(u, u)} \right\} \right\}, \quad (389)$$

$$η_{\hat{g}}(T_*) := \sup_{\omega, \phi \in \mathcal{M}(\mathcal{N})} \left\{ \frac{(d_{\hat{g}}(T_*(\omega), T_*(\phi)))^2}{(d_{\hat{g}}(\omega, \phi))^2} \right\}, \quad (390)$$

where

$$d_{\hat{g}}(\omega, \phi) := \inf_{c \in C} \left\{ \int_{0}^{1} dt \sqrt{\frac{D_l}{g_\phi(c(t), \dot{c}(t))}} \right\}, \quad (391)$$

and $C$ is defined as a class of all smooth curves $c : [0, 1] \ni t \mapsto c(t) \in \mathcal{M}(\mathcal{N})$ such that $c(0) = \omega$ and $c(1) = \phi$. Apart from Markov monotonicity of the above coefficients, Lesniewski and Ruskai proved that these coefficients are convex in $T_*$, and satisfy

$$1 \geq η_{D_l}(T_*) \geq η_{g^{D_l}}(T_*) \geq η_{\hat{g}}(T_*). \quad (392)$$

Now, let the inferential quantum dynamics be given by $D_l$ entropic projection on $\mathcal{M}(\mathcal{N})$, with the constraints $Q \subseteq \mathcal{M}(\mathcal{N})$ specified in terms of lower semi-continuous convex function $F : \mathcal{M}(\mathcal{N}) \to ] - \infty, +\infty\]$, $\mathcal{M}(\mathcal{N}) ;\omega \mapsto \arg \inf_{\phi \in \mathcal{M}(\mathcal{N})} \{D_l(\omega, \phi) + F(\phi)\} \in \mathcal{M}(\mathcal{N}). \quad (393)$

With the nontrivial examples of contraction coefficients at hand, we can propose to control the behaviour of constraints $Q$ under coarse grainings $T_*$ by means of markovian renormalisation semi-group transformation

$$F(\phi) \mapsto \frac{1}{η(T_*)} F(T_*(\phi)), \quad (394)$$

which amounts to subsequent coarse graining and rescaling of constraints. The choice of a particular form (394) of transformation of constraints can be justified either by appealing to arguments and insights based on ordinary renormalisation semi-group theory or by recalling another result of Lesniewski and Ruskai:

$$η_{D_l}(T_*) \neq η_{g^{D_l}}(T_*) \iff \exists \omega \neq \phi \text{ such that } \frac{1}{η_{D_l}(T_*)} D_l(T_*(\omega), T_*(\phi)) = D(\omega, \phi). \quad (395)$$
In such case, the invariant $\eta_D(T_\star)$ contains a complete information about the behaviour of distance $D_\star(\omega, \phi)$ under rescaling by coarse grainings $T_\star$. In view of (395), the aim of rescaling (394) is to obtain the same form of information dynamics (for a given initial state) independently of the coarse graining. In consequence, we will say that the quantum dynamics (393) is in a fixed point of markovian renormalisation semi-group transformation with respect to a contraction coefficient $\eta$ iff, given an initial state $\omega \in \mathcal{M}(\mathcal{N})$, $\omega \neq \phi$, the equations

$$
\begin{align*}
\eta(T_\star) F(\phi) &= F(T_\star(\phi)), \\
\eta(T_\star) D(\omega, \phi) &= D_\star(T_\star(\omega), T_\star(\phi))
\end{align*}
$$

(396)

hold for any $T_\star$ on $\mathcal{M}(\mathcal{N})$. If (396) is not satisfied, then the action of (394) generates the ‘flow’ of forms of dynamics along the ‘trajectory’ of semi-group of markovian morphisms.

As these examples show, quantum information geometry provides quantitative tools allowing to develop various renormalisation procedures for quantum inference, which possess explicit conceptual and quantitative meaning. In particular, the bregmannian and markovian renormalisation procedures reflect, respectively, two different problems: coarse graining and rescaling of the solution of dynamical (inferential) problem and coarse graining and rescaling of the definition of dynamical (inferential) problem. We refer to [30, 31, 32] for another (and more developed) approach to quantum information geometric renormalisation based on the use of markovian morphisms $T_\star$ (see also [79] for a pedagogical overview).

---

40 Consider $y = f(x)$, where $f$ is an arbitrary function. It is clear that the procedure used to control the quality of approximation of the initial data $x$ does not need to correspond to the procedure used to control the quality of approximation on the space of solutions of this equation.
Acknowledgments

This research was supported in part by Perimeter Institute for Theoretical Physics. Research at Perimeter Institute is supported by the Government of Canada through Industry Canada and by the Province of Ontario through the Ministry of Research and Innovation. This research was also partially financed by the National Science Center of the Republic of Poland (Narodowe Centrum Nauki) through the grant number N N202 343640. Early versions of this work were developed as a part of research supported by the grants: Mistrz 2007 grant of Foundation for Polish Science for Jerzy Lewandowski and his students, Quantum Geometry and Quantum Gravity grants 1955 and 2706 of European Science Foundation, and 182/N QGG/2008/0 grant of Ministerstwo Szkolnictwa Wyższego i Nauki. I acknowledge substantial reliance on the knowledge resources provided for free by Library Genesis (http://gen.lib.rus.ec) and Sci-Hub (http://sci-hub.cc). I believe that providing unrestricted free access to the results of scientific research is a matter of an elementary respect to other human beings. This paper grew out of the heuristic considerations in the preprints [205, 206, 207], motivated in turn by the ideas of Stanislaw Lem [225, 226] (information can be exchanged into energy and create a black hole), Jean Baudrillard [24, 25] (symbolic systems of information gravitate), and Antoni Kępiński [192, 193] (time of entropic processing and time of energy flow are a priori independent). I am indebted to Stanislaw Woronowicz for introducing me to the theory of noncommutative flow of weights, which allowed me to make some of these ideas mathematically sound. I want to warmly thank: Cédric Bény, Pavel Bóna, Dylan Butson, John DeBrota, Jan Derezínski, Paolo Gibilisco, Frank Hellmann, Carlos Guedes, Anna Jenčová, Wojtek Kamiński, Jerzy Kijowski, Jacek Kopeć, Władysław A. Majewski, Włodek Natorf, Dmitri˘ı Pavlov, Claude-Alain Pillet, Carlos C. Rodríguez, David Sherman, Ray Streater, and Karol Życzkowski for discussions, Marco Favretti for sharing his unpublished preprint [100], Jerzy Lewandowski for his trust in, and support of, my nonorthodox research, Chris Isham for his interest in, and comments on, the early version of this paper, Fotini Markopoulou, Olaf Dreyer, Jamie Vicary, Cecilia Flori, and Tomasz Kołodziejski for their generous hospitality in London, Nottingham, Oxford, and Berlin during the periods of intense work on this project, Basia Baranowska, Janka Spicha-Konarzewska, and Aneta Pękała for sharing their life, love and support, and my flatmates Teresa Szczepińska, Rafał Gröger, and Agnieszka Gronowicz, as well as medical teams of Szpital Kliniczny Dzieciątka Jezus and Centralny Szpital Kliniczny MSW, for rescuing me from the carbon monoxide brain death.
