ABSTRACT This work deals with the secrecy performance analysis of a dual-hop RF-FSO DF relaying network composed of a source, a relay, a destination, and an eavesdropper. We assume the eavesdropper is located close to the destination and overhears the relay’s transmitted optical signal. The RF and FSO links undergo \((\alpha - \kappa - \mu)\)-shadowed fading and unified Málaga turbulence with pointing error. The secrecy performance of the mixed system is studied by deriving closed-form analytical expressions of secure outage probability (SOP), strictly positive secrecy capacity (SPSC), and intercept probability (IP). Besides, we also derive the asymptotic SOP, SPSC, and IP upon utilizing the unfolding of Meijer’s \(G\) function where the electrical SNR of the FSO link tends to infinity. Finally, the Monte-Carlo simulation is performed to corroborate the analytical expressions. Our results illustrate that fading, shadowing, detection techniques (i.e. heterodyne detection (HD) and intensity modulation and direct detection (IM/DD)), atmospheric turbulence, and pointing error significantly affect the secrecy performance. In addition, better performance is obtained exploiting the HD technique at the destination relative to IM/DD technique.

INDEX TERMS Intercept probability, Málaga turbulence, physical layer security, secure outage probability.

I. INTRODUCTION

A. BACKGROUND

Free space optical (FSO) technology has drawn significant attention of the research communities compared to traditional radio frequency (RF) technologies in wireless communication applications due to advantages of high-frequency bandwidth, high speed, high security, large transmission capacity, disaster recovery, fast deployment, unlicensed spectrum, back-haul for wireless cellular networks, solution for the last-mile access problem, fiber backup, and no interference, among many others [1]. However, pointing error and atmospheric turbulence highly impact the system performance of FSO schemes [2]–[5] that can be mitigated by utilizing a dual-hop mixed RF-FSO relaying system.

B. LITERATURE SURVEY

Since the wireless medium is time-varying in nature, recently, researchers are devoting their concentrations to composite fading models that can unify the characteristics of a wide range of classical multipath / generalized fading models, thereby applicable to more practical / real-life scenarios [6]. \(\alpha - \mu\) [7], \((\alpha - \mu)\)-shadowed [8], \(\kappa - \mu\) [9], \((\kappa - \mu)\)-shadowed [10], and \(\eta - \mu\) [11], [12] are widely used as
generalized models in the literature. To obtain further generalization, authors in [13] proposed $\alpha - \kappa - \mu$ and $\alpha - \eta - \mu$ distributions that were further generalized by $\alpha - \kappa - \eta - \mu$ model [14]. It can be noted that the authors considered randomly fluctuated dominant specular components, non-linearity of the propagation medium, non-line-of-sight (NLOS), line-of-sight (LOS) propagation link, etc., criterion for channel modeling. Considering all of those channel effects, $(\alpha - \kappa - \mu)$-shadowed (AKM-shadowed) model was formulated in [15] that possesses a good mathematical tractability and offers a natural generalization to all the aforementioned channel models.

In recent years, researchers have carried out a mesmerizing amount of works on FSO communication systems [16]–[21]. The analysis of the system performance considering the FSO scheme was first performed in [22] focusing on the impact of turbulence-induced fading. This model was further upgraded with multiple receive and transmit apertures in the existence of both background and shot noises [23]. Data transmission using series and parallel relays in FSO communication scheme was introduced in [24]. The authors in [25], [26] performed the error control coding for two different FSO models. A Unique multi-input multi-output (MIMO) model was proposed in [27] with multiple transmitters and receivers considering the effect of fading and pointing error. The adverse effect of boresight pointing error on a FSO link for both intensity modulation / direct detection (IM/DD) and heterodyne detection (HD) techniques was analyzed in [28].

The unification of the existing FSO models was done by introducing the Málaga turbulence model in [29].

Recently, mixed RF-FSO systems have been investigated thoroughly to eliminate atmospheric turbulence dependency of the FSO links. In such types of scenarios, long-distance communication is performed over the RF hop whereas shorter distance is accomplished over the FSO hop. The authors in [30] studied the performance of amplify-and-forward (AF) fixed gain relaying technique in terms of outage probability (OP) considering Rayleigh-$\Gamma$ fading scenario. The performance of a nearly similar model was analyzed [31] for both HD and IM/DD techniques. Authors in [32] investigated the impact of aperture averaging of the FSO link. In [33]–[35], authors considered both decode-and-forward (DF) and AF relaying methods for dual-hop RF-FSO network and derived closed-form expressions (CFE) for OP, ergodic capacity (EC), and bit error rate (BER). Similar performance parameters were also investigated [36] where the authors choose different fading models as for both RF and FSO link. The increment in atmospheric temperature causes the thermal expansion in the buildings around us which in turn produces non-zero boresight pointing error. Authors in [37] modeled a RF-FSO system to analyze the impact of such error.

With the rapid growth of wireless networks, secret information transmission in presence of adversaries is an extremely critical issue. The traditional security methods depend on cryptographic techniques at upper layers of wireless networks that are difficult to utilize [38], [39]. In this perspective, physical layer security (PLS) is the only solution that utilizes the randomness of the propagation channel to enhance the secrecy level [40]–[43]. The effect of imperfect channel state information was considered in [44] and the performance analysis was carried out in terms of secrecy outage probability (SOP) adopting the fixed gain relaying technique. In [45], the authors observed that RF hop has a little impact on SOP and average secrecy capacity (ASC) performances relative to FSO hop. The position of eavesdropper was considered close to the destination in [46], [47] where the authors presented the expressions of SOP and strictly positive secrecy capacity (SPSC) with DF relaying system. A passive RF eavesdropping scheme was used in mixed RF-FSO systems over $\Gamma\Gamma$ [39], [48], Málaga [49]–[51], exponentiate-Weibull [44], [52], etc., scenarios to obtain ASC, SOP, and SPSC. The effects of transmit antenna selection (TAS) scheme over the RF hop in a RF-FSO mixed system was examined by [53]. In [54], [55], authors compared the performance between RF and FSO eavesdropping over Málaga and double generalized Gamma (DGG) models and demonstrated that FSO technology is more secure than RF technology.

C. MOTIVATION AND CONTRIBUTIONS

Based on aforementioned literature, it is seen that among the existing PLS works on RF-FSO schemes, RF hop is typically assumed to experience multipath / generalized fading while none of these works considered the impact of shadowing on the RF hop. In this work, we consider a mixed RF-FSO dual-hop DF relaying system where the RF and FSO links, respectively, experience AKM-shadowed fading and Málaga turbulence fading model included with pointing error. We consider the position of the eavesdropper is very close to the destination and can decipher the transmitted optical signals from the relay. Our main contributions in this work are pointed as follows.

- We first realize the probability density functions (PDFs) and cumulative distribution functions (CDFs) of the AKM-Shadowed link and Málaga turbulence link for the individual hops of the considered dual-hop system. Since our considered RF and FSO models account for a high form of generality, our obtained results can be ascertained as a generalization of the existing results in [46], [50].

- To analyze the secrecy performance, we derive the CFEs for the SOP, SPSC, and intercept probability (IP). To obtain more practical insights, the asymptotic expressions for these performance parameters are also provided. Finally, we present Monte-Carlo simulations to verify the accuracy of the CFEs.

- Capitalizing on the final expressions of the secrecy performance parameters, we observe impacts of fading, shadowing, atmospheric turbulence, pointing error, etc., on the secrecy of the proposed scenario. Additionally,
we also present a comparison between the performance of two detection techniques i.e. HD and IM/DD techniques.

D. ORGANIZATION
The rest of the paper is arranged in the following manner. The system model is described in Section II including formulations of the fading channels. In Section III, expressions for SOP, SPSC, and IP are derived in both exact and asymptotic forms. Analytical and simulation results are presented in Section IV, and finally, the concluding remarks are provided in Section V.

II. SYSTEM MODEL AND PROBLEM FORMULATION
We consider a combined RF-FSO DF-based relaying system as demonstrated in Fig. 1. Here, information is transferred from a stable source S to a destination D via a relay R that works as an intermediate medium between S and D. It is considered that an unexpected eavesdropper E tries to hijack the classified information from R that is supposed to reach D. Similar to [56], we presume that E is firmly located around D. S with a single antenna transmits information to R through an independent and identically distributed (i.i.d.) AKM-shadowed RF fading link where R consists of one receiving antenna and one transmit aperture. After receiving the RF signal, R converts the same to an optical signal and then re-transmits it. Both R — D and R — E links are connected linked via FSO technology experiencing Málaga (M) turbulence with pointing error. Here, D and E both contain one receive aperture for receiving the optical signals.

![Diagram of the dual-hop mixed RF-FSO system.](image)

**FIGURE 1.** The dual-hop mixed RF-FSO system.

A. SNRs OF EACH LINK
As for the considered communication scenario in Fig. 1, the instantaneous signal-to-noise ratios (SNRs) denoted by $S - R$, $R - D$, and $R - E$ links are $\gamma_r$, $\gamma_d$, and $\gamma_e$, respectively. These terms take arithmetic forms such as $\gamma_r = \phi_r \| \beta_r \|^2$, $\gamma_d = \phi_d \| \beta_d \|^2$, and $\gamma_e = \phi_e \| \beta_e \|^2$, where $\beta_r$, $\beta_d$, and $\beta_e$ represent channel gains, and $\phi_r$, $\phi_d$, and $\phi_e$ represent average SNRs of the $S - R$, $R - D$, and $R - E$ links, respectively. As relay R employs DF relaying scheme, end-to-end SNRs for both main $S - R - D$ receiver link and eavesdropper $S - R - E$ receiver link are formulated as [57, Eq. (5)]

$$
\begin{align}
\gamma_{rd} &= \min \{ \gamma_r, \gamma_d \}, \\
\gamma_{re} &= \min \{ \gamma_r, \gamma_e \}.
\end{align}
$$

B. RF CHANNEL
As the link between S and R experiences AKM-shadowed distribution, the PDF can be expressed as [15, Eq. (4)]

$$
\gamma_r = A_1 \gamma^{\frac{\mu}{2}} - 1 - A_2 \gamma^\frac{\alpha}{2} F_1(x, \mu; A_3 \gamma^\frac{\alpha}{2}),
$$

where $A_1 = \frac{x^\mu \phi_r \gamma^{\frac{\mu}{2}}}{2 \Gamma(\mu+\gamma \gamma_2) \Gamma(\mu+\gamma \gamma_3)}$, $A_2 = \frac{1}{d(x_2\gamma^\frac{\alpha}{2})}$, and $A_3 = \frac{\mu}{d(\mu+\gamma \gamma_2) \Gamma(\mu+\gamma \gamma_3)}$. The terms $x$, $\mu$, $\alpha$, and $\gamma$ are all real shape parameters with non-negative values i.e. $\alpha$ is a power term indicating non-linearity nature of signal envelop [7], $\gamma$ defines the ratio of total amount of powers between dominant and scattered waves [10], and $\mu$ and $x$ denote number of cluster and fading severity parameters, respectively, [15]. $\Gamma(\cdot)$ represents Gamma function [58, Eq. (8.310)]. The function $F_1(\cdot)$ is the confluent hypergeometric function as defined in [59, Eq. (13.1.2)]. The constant term $d$ is described as

$$
d = \left[ x^\Gamma(\mu+\gamma \gamma_2) \frac{\mu \gamma^{\frac{\alpha}{2}}}{\Gamma(\mu+\gamma \gamma_2) \Gamma(\mu+\gamma \gamma_3)} \right].
$$

Here, the function $F_1(\cdot)$ is the Gauss hypergeometric function as defined in [59, Eq. (15.1.1)]. AKM-shadowed is a composite fading model that houses many multipath and generalized fading channel models. Such a model promises to provide more insights over a wide range of variations of channel conditions that is treated as more practical propagation environment by the wireless communication researchers [60], [61]. Table 1 lists some familiar RF fading channels that can be obtained as special cases of AKM-shadowed fading channel.

**TABLE 1.** Special cases of AKM-shadowed composite fading channel [15, Table 1].

| Channels | AKM-Shadowed Fading Parameters |
|----------|---------------------------------|
| Rayleigh | $\alpha = 2$, $\kappa = 0$, $\mu = 1$ |
| Nakagami-$m$ | $\alpha = 2$, $\kappa = 0$, $\mu = m$ |
| $\kappa - \mu$ | $\alpha = 2$, $\kappa = \mu = m$, $x \to \infty$ |
| $\eta - \mu$ | $\alpha = 2$, $\kappa = (1 - \eta)/(2\eta)$, $\mu = 2\mu$, $x = \mu$ |
| Weibull | $\alpha = \alpha$, $\kappa = 0$, $\mu = 1$ |
| $\kappa - \mu$ | $\alpha = \alpha$, $\kappa = \mu = m$, $x \to \infty$ |

Utilizing [58, Eq. (9.14.1)], (2) is alternatively expressed as

$$
f_{\gamma_r}(\gamma) = A_1 \sum_{i=0}^{\infty} A_2^\gamma^{\frac{\alpha(i+1)}{2}} - e^{-A_2^\gamma \frac{\alpha}{2}},
$$

VOLUME 9, 2021

133851

N. A. Sarker et al.: On Intercept Probability and Secure Outage Analysis
where \( A_4 = \frac{x^4A_1}{\mu^4} \). The CDF of this channel can be found by utilizing

\[
F_{y_4}(\gamma) = \int_0^\gamma f_{y_4}(\gamma) d\gamma.
\]

(4)

Placing (3) into (4), utilizing [58, Eqs. (3.381.8) and (8.352.6)], and performing integration, (4) is obtained as

\[
F_{y_4}(\gamma) = 1 - \frac{2A_1}{\alpha} \sum_{i=0}^{\infty} \sum_{j=0}^{\mu+i-1} A_5 \gamma^\frac{a_i}{2} e^{-A_2 \gamma^\frac{b_i}{2}},
\]

(5)

where \( A_5 = \frac{A_4 \Gamma(\mu+i)}{\beta^2 A_2^{\mu+i}} \).

C. FSO CHANNEL

Now, PDF of FSO link, formulated by unified \( \mathcal{M} \) turbulence model, is expressed as [29, Eq. (9)]

\[
f_{y_m}(\gamma) = \gamma \sum_{q_m=0}^{b} h_{qm} \cdot \mathcal{B} \left[ \left( \gamma \left( \frac{U_m}{\beta m} \right) \right)^{\frac{1}{2}} \left( \frac{\epsilon^2 + 1}{\epsilon^2} \right)^{a} \right],
\]

(6)

where \( m \in \{ d, e \} \) correspond to \( R - D \) and \( R - E \) links, respectively,

\[
\begin{align*}
Z_1 &= \frac{2^{1-s_m} \epsilon^2 a_{s_m}^{1/2}}{r_m b} \Gamma(a) \left( \frac{r_m b + \zeta_{l_m}}{r_m b + \zeta_{l_m}} \right)^{b + \frac{s_m}{2}}, \\
Z_2 &= \frac{2^{1-s_m} \epsilon^2 a_{s_m}^{1/2}}{r_m b + \zeta_{l_m}} \left( \frac{r_m b + \zeta_{l_m}}{r_m b + \zeta_{l_m}} \right)^{b + \frac{s_m}{2}}, \\
h_{qm} &= j_{qm} \left( \frac{ab}{r_m b + \zeta_{l_m}} \right)^{s_m}, \\
j_{qm} &= \frac{(b - 1)}{q_m - 1} \left( \frac{r_m b + \zeta_{l_m}}{q_m - 1} \right)^{1/q_m - 1} \left( \frac{\zeta_{l_m}}{r_m} \right) \left( \frac{a}{b} \right)^{q_m - 1}.
\end{align*}
\]

\( Z \in \{ B, C \} \) correspond to \( R - D \) and \( R - E \) links, respectively, \( a \) and \( b \) both are related to the turbulence conditions in atmosphere with \( a \) being firmly related to the effective number that is followed by the large-scale cells and \( b \) being related to the scattering process [62], \( \epsilon \) is identified as a ratio between the tantamount beam radius signal beam and the standard deviation (jitter) due to pointing error misalignment, \( s_m \) represents detection type at the receiver (i.e. \( s_m = 1 \) for HD technique and \( s_m = 2 \) for IM/DD technique), \( U_m \) represents the electrical SNR of FSO link that is expressed dependent on the detection technique \( s_m \) such that \( U_1 = \phi_m \) for HD technique and \( U_2 = \frac{a \epsilon^2}{a + 1}(\epsilon^2 + 1)^{2} \Gamma(a + 2 \zeta_{l_m} + 2 \zeta_{l_m}) \phi_m \) for IM/DD technique [29], \( r_m \) represents the average power of scattering components that is received by the off-axis eddies subjected to the FSO link [63], \( \zeta_{l_m} = \zeta_m + 2h_m \theta_0 + \sqrt{2h_m \alpha \pi \cos(\theta_{l_m} - \theta_{m})} \) i.e. average power subjected to the coherent contributions in the FSO link, \( \zeta_m = 2h_m \theta_0 \) represents the average power of LOS component, \( h_m \) is the average power of all scattered components, \( \phi_m \) denotes the total amount of scattering powered placed at LOS component with the limit \( 0 \leq \phi \leq 1 \), \( \theta_{l_m} \) and \( \theta_{m} \) both are the LOS deterministic phases [63], and \( G(.) \) symbolizes the Meijer’s \( G \) function as defined in [58, Eq. (9.301)]. Málaga distribution is one of the most popular FSO fading models among optical wireless communication researchers due to its outstanding generic characteristics. Table 2 lists some classical FSO fading channels that can be obtained from the unified \( \mathcal{M} \) turbulence model via tuning some of its parameters.

| Channels | \( \mathcal{M} \) Turbulence Fading Parameters |
|----------|-----------------------------------------------|
| \( \Gamma' \) | \( \phi = 1, r_m = 0, \zeta_m = 1 \) |
| Rice-Nakagami | \( \phi = 0 \) |
| Lognormal | \( \phi = 0, r_m \to 0 \) |
| \( K \) distribution | \( \phi = 0, b = 1 \) |

The CDF for this link is expressed as [29, Eq. (11)]

\[
F_{y_m}(\gamma) = Z_3 \sum_{q_m=0}^{b} w_{qm} \cdot \mathcal{B} \left[ \left( \frac{Z_4}{U_m} \right) \left( \frac{1}{l_{m_1}} \right) \left( \frac{l_{m_2}}{\gamma} \right) \right],
\]

(7)

where \( Z_3 = \frac{z_{m_1} z_{m_2}}{(2\pi)^{m_1+2} \cdot z_{m_2}} \cdot w_{qm} = h_{qm} \cdot \frac{a + q_m - 1}{s_m} \cdot Z_4 = \frac{z_{m_1}}{s_m} \cdot \frac{z_{m_2}}{s_m} \) are series, described as \( l_{m_1} = \left\{ l_{m_1}^{s_m + 1}, \ldots, l_{m_1}^{s_m + 1} \right\} \) containing \( s_m \) terms and \( l_{m_2} = \left\{ \frac{a + q_m - 1}{s_m}, \frac{a + q_m - 1}{s_m}, \ldots, \frac{a + q_m - 1}{s_m}, \frac{a + q_m - 1}{s_m} \right\} \) containing \( 3s_m \) terms.

D. SECURITY CAPACITY

For secured transmission between \( S \) to \( D \) via intermediate relay \( R \), we have to find out the secrecy rate of the system wherein confidential and secrete communication can be transmitted by dumping the unwanted effects of the eavesdropper. For the considered dual-hop system in Fig. 1, secrecy capacity (SC) must be defined for both hops (i.e. \( S - R \) and \( R - D \)). The network in Fig. 1 demonstrates first hop is independent of the effects of eavesdropper, so instantaneous SC for the RF hop is defined as

\[
T_{SR} = \frac{1}{2} \log_2 (1 + \gamma_e).
\]

(8)

For main FSO link that is largely affected by the eavesdropper, instantaneous SC for FSO hop is defined as

\[
T_{RD} = \left[ \frac{1}{2} \left( \log_2 (1 + \gamma_d) - \log_2 (1 + \gamma_e) \right) \right]^{+},
\]

(9)

where \( [z]^+ = \max \{z, 0\} \). For DF-based relaying network, the system considered in Fig. 1 can be described as a series system where such dual-hop network will usually be dominated by worst hop and the instantaneous SC is expressed as [64, Eq. (13)]

\[
T_{SD} = \min(T_{SR}, T_{RD}).
\]

(10)

III. PERFORMANCE ANALYSIS

In this section, we derive closed-form expressions for SOP, SPSC, and IP in both exact and asymptotic forms.
A. SECRECY OUTAGE PROBABILITY

SOP is an important and crucial performance metric for secrecy measurement in wireless systems. It is basically a parameter that indicates the probability of the instantaneous SC falling below the target SC ($T_c$). For the proposed RF-FSO relaying system, SOP can be defined as [65]

$$SOP = Pr\{T_{SD} < T_c\}. \quad (11)$$

We can rewrite (11) by using (10) as

$$SOP = Pr\{\min(T_{SR}, T_{RD}) < T_c\}
= 1 - Pr\{\min(T_{SR}, T_{RD}) \geq T_c\}
= 1 - Pr\{T_{SR} \geq T_c\}Pr\{T_{RD} \geq T_c\}. \quad (12)$$

Substituting (5)-(7) into (12), we have

$$SOP = \int_0^\infty F_\gamma(\varphi + \varphi - 1)f_\gamma(\gamma)d\gamma
\times (1 - F_\gamma(\varphi - 1)) + F_\gamma(\varphi - 1), \quad (13)$$

where $\varphi = 2^{2T_c}$. Due to mathematical complexities, we derive the SOP at lower bound. Letting the condition $\gamma_e \rightarrow \infty$, the lower bound of SOP can be evaluated from (13) as [66]

$$SOP \geq SOP_L \equiv \int_0^\infty F_\gamma(\varphi + \varphi - 1)f_\gamma(\gamma)d\gamma
\times (1 - F_\gamma(\varphi - 1)) + F_\gamma(\varphi - 1). \quad (14)$$

Plugging (5)-(7) into (14) and integrating utilizing [67, Eq. (2.24.1.1)] by means of some mathematical simplifications, actual expression of the lower bound of SOP is obtained as in (15), as shown at the bottom of the page, where $s_M = s_e + 3s_d$, $s_e = 3s_e + s_d$, and $s \equiv 2A_1A_3(\varphi - 1)\frac{\alpha}{\alpha}$.

Meijer’s $G$ function in (15), the asymptotic expression of lower bound SOP is obtained as (16), shown at the bottom of the page, where $L_1 = (1 - \xi_{d_1}, 1, \xi_{d_1})$ and $L_2 = (\xi_{e_2}, 0, 1 - \xi_{d_1})$.

$$SOP = \Pr\{L_1 < T_c\}. \quad (15)$$

The asymptotic expression in [50, Eq. (36)] can be obtained from (16) with $\alpha = \mu = 2$ and $\kappa = 0$.

B. STRICTLY POSITIVE SECRECY CAPACITY

For ensuring a secure communication, SPSC is one of the fundamental parameters that is used to place importance to the existence of the SC. According to [68], the probability of SPSC can be defined as

$$SPSC = Pr\{\min(T_{SR}, T_{RD}) > 0\}
= Pr\{T_{SR} > 0\}Pr\{T_{RD} > 0\}. \quad (17)$$

The two probability terms defined in (17) can be evaluated as

$$Pr\{T_{SR} > 0\} = Pr\left\{\frac{1}{2}\log_2(1 + \gamma_{T}) > 0\right\}
= Pr\{\gamma_T > 0\} = 1, \quad (18)$$

and

$$Pr\{T_{RD} > 0\}
= Pr\left\{\frac{1}{2}\log_2(1 + \gamma_{T}) - \log_2(1 + \gamma_{e}) > 0\right\}
= Pr\{\gamma_{T} > \gamma_{e}\} = 1 - \int_0^\infty F_\gamma(\gamma)f_\gamma(\gamma)d\gamma. \quad (19)$$

Plugging (18) and (19) into (17), we get

$$SPSC = 1 - \int_0^\infty F_\gamma(\gamma)f_\gamma(\gamma)d\gamma. \quad (20)$$

Placing the values of (6) and (7) into (20), performing integration utilizing [67, Eq. (2.24.1.1)], and employing mathematical simplifications, the exact form of (20) is evaluated to

$$SPSC = 1 - \sum_{q_{d,e}} G_{s_M + 1, s_e + 1} \left[ C_4 U_d \frac{1 - l_{d_1}, 1, l_{e_1}}{B_d U_e} \right] \left[ l_{e_2}, 0, 1 - l_{d_1} \right]. \quad (21)$$

The expression of SPSC as given in (21) can be reduced to the Rayleigh-$\Gamma$ scenario [46, Eq. (23)] with $\alpha = 2$, $\kappa = r_d = r_e = 0$, $\mu = 0 = \xi_{d_1} = \xi_{e_1} = 1$.

1) ASYMPTOTIC EXPRESSION

To get better analytical and tractable understanding on secrecy performance, we derive asymptotic expressions of our secrecy performance metrics by considering the condition $U_m \rightarrow \infty$. Applying the formula given in [50, Eq. (29)] and performing some mathematical manipulations on the
C. INTERCEPT PROBABILITY

The probability at which the eavesdropper succeeds in intercepting the data upheld at the actual receiving device is addressed as intercept probability (IP). It basically indicates the probability that SC is less than zero. For the proposed communication scenario, IP can be mathematically defined as [69, Eq. (31)]

\[
IP = \Pr \{ \gamma_d < 0 \} = \Pr \{ \gamma_e < \gamma_c \} = \int_0^\infty F_{\gamma_d}(\gamma) f_{\gamma_e}(\gamma) d\gamma.
\] (23)

Plugging (6) and (7) into (23), performing integration utilizing [67, Eq. (2.24.1.1)], and simplifying the expression, IP is evaluated to

\[
IP = \sum_{q_d, e} G_{s_3+1, 3_s+1} \left[ \frac{C_4 U_d}{B_4 U_e} \right] e^{-1 l_d + 1, l_e}.
\] (24)

1) ASYMPTOTIC EXPRESSION

Applying identical process as was performed for (16) and (22), the asymptotic expression of IP in (24) is expressed as (25), shown at the bottom of the page.

IV. NUMERICAL RESULTS

In this section, we present the numerical results utilizing the deduced expressions of secrecy parameters i.e. SOP, SPSC, and IP. Besides, we also plot Monte-Carlo simulation results to validate our analysis.1 The whole analysis is performed considering \( \alpha \geq 0, \kappa \geq 0, \mu \geq 0, T_{SD} = 1, T_c = 0.5 \) bits/sec/Hz, \( x \geq 0, (a, b) = (2.296, 2) \) for strong turbulence, (4.2, 3) for moderate turbulence, and (8, 4) for weak turbulence, \( s_d = s_e = (1, 2) \), and \( \epsilon = 1.1 \) and 6.7.

Figures 2 and 3 depict the impact of channel parameters of AKM-shadowed fading channel (i.e. \( x, \alpha, \kappa, \) and \( \mu \)) on secrecy performance of the proposed system. For this purpose, the SOP is plotted against \( \phi_e \) in both figures. It can clearly be seen that with the increase in \( x, \alpha, \kappa, \) and \( \mu \), the SOP significantly decreases as testified in [15]. In fact, an increase in \( \alpha, \kappa, \) and \( \mu \) decreases the overall fading thereby improving the secrecy performance. Additionally, higher values of \( x \) denotes lower amount of shadowing and hence the SOP decreases with \( x \).

1The AKM-shadowed and \( M \) random variables are generated in MATLAB environment using \texttt{gamrnd(...)} command, where we consider 100,000 average independent trials to obtain each value of the secrecy parameters [49], [70]. Similar to [38], [49], we can observe a clear agreement between the analytical and simulation results which justifies the validity of the mathematical expressions.

\[
\text{SPSC}_\infty = 1 - \sum_{q_d, e} \sum_{p=1}^{3_s} \frac{G_{s_3+1, 3_s+1}}{\prod_{l=1}^{3_s+1} \Gamma(1 + l, 1 - L_{1,p})} \prod_{l=1}^{3_s+1} \Gamma(1 + l, 1 - L_{1,p}) \prod_{l=1}^{3_s+1} \Gamma(1 + l, 1 - L_{1,p}) \left( \frac{C_4 U_d}{B_4 U_e} \right) \left( L_{1,p-1} \right).
\]

\[
\text{IP}_\infty = \sum_{q_d, e} \sum_{p=1}^{3_s} \frac{G_{s_3+1, 3_s+1}}{\prod_{l=1}^{3_s+1} \Gamma(1 + l, 1 - L_{1,p})} \prod_{l=1}^{3_s+1} \Gamma(1 + l, 1 - L_{1,p}) \prod_{l=1}^{3_s+1} \Gamma(1 + l, 1 - L_{1,p}) \left( \frac{C_4 U_d}{B_4 U_e} \right) \left( L_{1,p-1} \right).
\]

Impact of two types of detection techniques (HD and IM/DD) at the receiver and eavesdropper on secrecy performance are demonstrated in Figs. 4-6. Results demonstrate...
that better secrecy performance can be achieved while employing HD technique ($s_d = s_e = 1$) at both $D$ and $E$ relative to IM/DD technique ($s_d = s_e = 2$). The reason behind this outcome is due to the fact of obtaining a better SNR at the destination with HD technique compared to IM/DD technique. Our exhibited results also match with the results exhibited in [46], [50].

Besides the detection types and pointing error, atmospheric turbulence also affects secrecy performance as demonstrated in Figs. 4-9. Analytical and simulation results indicate that similar to results in [46] and [50], our secrecy performance is the best at weaker turbulence scenarios and vice versa holds true too. These outcomes are obvious as severe turbulence affects the received SNR at the destination quite drastically.
relative to weaker turbulence. The asymptotic curves also shows a close tightness with the analytical results at high SNR regime and the figures indicate that the asymptotes require time to stabilize.

We observe the impact of electrical SNR $U_e$ of the $R - E$ link in Fig. 10 with respect to SPSC. Our results demonstrate the expected outcome as SPSC decreases when $U_e$ increases from a lower to a higher value. This occurs since higher $U_e$ signifies a stronger $R - E$ link. A similar type of result was also exhibited in [50] that strongly justifies our results.

The generic characteristics of AKM-shadowed fading is demonstrated in Fig. 11 following Table 1. It is observed from Fig. 11 that not only multipath fading channels (e.g. Rayleigh, Nakagami-$m$, and Weibull), but also generalized fading channels (e.g. $\eta - \mu$, $\kappa - \mu$, and $\alpha - \kappa - \mu$) can be obtained as special cases to our proposed RF model. Figure 12 demonstrates the generic characteristics of $M$ distribution by utilizing the parameter values as presented in Table 2. It can clearly be observed that $K$ distribution, Rice-Nakagami, 00, Lognormal, etc., models can easily be obtained as special cases to our work.

A. COMPARATIVE ANALYSIS WITH EXISTING RELATED LITERATURE

We assume our RF link experiences the AKM-shadowed fading model whereas the FSO link experiences the unified $M$
turbulence with pointing error impairment. AKM-shadowed is a composite fading model that comprises a large number of multipath and generalized fading models as listed in Table 1. On the other hand, the $M$ turbulence model also houses immense generic characteristics (Table 2) that make it one of the most popular FSO turbulence models among optical wireless communication researchers. Hence, our hybrid RF-FSO system model can unify a wide range of both existing and non-existing RF-FSO hybrid scenarios for which a summary is deduced in Table 3. Subsequently, Fig. 13 demonstrates this generalization graphically wherein we can clearly observe the proposed model exhibits significant generality and novelty relative to the open literature.

### V. CONCLUSION

This work focuses on the protection of secret information against FSO eavesdropping over a RF-FSO mixed system where the RF and FSO links are assumed to follow AKM-shadowed and Málaga turbulence fading models. Secrecy analysis was carried out in terms of closed-form expressions for three secrecy metrics i.e. SOP, SPSC, and IP that were validated via Monte-Carlo simulations. Additionally, we also investigated the asymptotic expressions for each metric to demonstrate more useful insights and tractability, and it is observed the asymptotic expressions exhibit appropriate tightness in high SNR regimes. Numerical results reveal that fading, shadowing, atmospheric turbulence, and pointing misalignment error have tremendous detrimental impacts on the secrecy performance. Moreover, the HD technique always outperforms IM/DD technique. Since, in our considered scenario, both RF and FSO links are generalized, our demonstrated results exhibit superiority over the existing literature via providing these results to the design engineers while working on more real-life systems considering higher order of randomness in the propagation channel.

---

**NOOR AHMAD SARKER** received the Bachelor of Science (B.Sc.) degree in electronics and telecommunication engineering (ETE) from Rajshahi University of Engineering and Technology (RUET), Rajshahi, Bangladesh. His research interests include physical layer security, cooperative communication, and FSO communication.

**A. S. M. BADRUDDUZA** (Member, IEEE) received the Bachelor of Science (B.Sc.) and the Master of Science (M.Sc.) degrees in electrical and electronic engineering (EEE) from Rajshahi University of Engineering and
techology (RUET), Rajshahi, Bangladesh, in 2016 and 2019, respectively.

From September 2016 to July 2017, he was a Lecturer with the Department of EEE, Bangladesh Army University of Engineering and Technology (BAUET), Natore, Rajshahi. From July 2017 to June 2020, he was a Lecturer with the Department of Electronics and Telecommunication Engineering (ETE), RUET. Since June 2020, he has been working as an Assistant Professor with the Department of ETE, RUET. He has authored/coauthored more than 30 international journals/conference publications. His research interests include physical layer security in multicast, cellular and cooperative networks, free space optics (FSO), underwater optics (UWO), and NOMA systems.

Mr. Badrudduza has been affiliated with IEEE, since 2020. He was a recipient of two EEE Association Awards (Student of the Year Award) from RUET for his outstanding academic performances in the 1st and 4th-year examinations while pursuing his B.Sc. engineering degree and two Best Paper Awards for two different research articles from the IEEE Region 10 Symposium (TENSYMP2020), and the IEEE 3rd International Conference on Telecommunication and Photonics (ICTP2019). He is an active reviewer for several IEEE journals.

**S. M. RIAZUL ISLAM** (Member, IEEE) was an Assistant Professor with the University of Dhaka, Bangladesh, where he was a Lecturer with the Department of Electrical and Electronic Engineering, from 2005 to 2014. He worked with Samsung Research and Development Institute, Bangladesh, as a Chief Engineer with the Department of Solution Laboratory for Advanced Research, in 2014. From 2014 to 2017, he worked as a Postdoctoral Fellow with the Wireless Communications Research Center, Inha University, South Korea. From 2016 to 2017, he was also affiliated as a Postdoctoral Fellow with Memorial University, Canada. Since March 2017, he has been working as an Assistant Professor with the Department of Computer Science and Engineering, Sejong University, South Korea. His research interests include wireless communications, the Internet of Things, and applied artificial intelligence.
SHEIKH HABIBUL ISLAM received the Bachelor of Science (B.Sc.) degree in electrical and electronic engineering (EEE) degree from Rajshahi University of Engineering and Technology (RUET), Rajshahi, Bangladesh. His research interests include FSO communication, physical layer security, and NOMA systems.

MILTON KUMAR KUNDU (Member, IEEE) received the B.Sc. degree in electrical and electronic engineering (EEE) from Rajshahi University of Engineering and Technology (RUET), Rajshahi, Bangladesh, in 2016. From May 2017 to February 2019, he worked as a Lecturer with the Department of Electrical and Computer Engineering (ECE), RUET. He is currently the Advisor of the IEEE RUET Industry Applications Society (IAS) Student Branch Chapter. His research interests include security aspects of cooperative and physical-layer networks and wireless multicasting.

Mr. Kundu has won several awards, including the 2nd runner-up award in regional Mathematical Olympiad and EEE Association Award (Student and wireless multicasting). He has also won two best paper awards for two different research articles from the IEEE Region 10 Symposium (TENSYMP 2020), and the IEEE 3rd International Conference on Telecommunication and Photonics (ICTP 2019).

IMRAN SHAFIQUE ANSARI (Member, IEEE) received the B.Sc. degree (Hons.) in computer engineering from King Fahd University of Petroleum and Minerals (KFUPM), in 2009, and the M.Sc. and Ph.D. degrees from King Abdullah University of Science and Technology (KAUST), in 2010 and 2015, respectively.

From May 2009 to August 2010, he was a Visiting Scholar with Michigan State University (MSU), East Lansing, MI, USA. From June 2010 to August 2010, he was a Research Intern with Carleton University, Ottawa, ON, Canada. From April 2015 to November 2017, he was a Postdoctoral Research Associate (PRA) with Texas A&M University at Qatar (TAMUQ). From November 2017 to July 2018, he was a Lecturer (Assistant Professor) with the Global College of Engineering and Technology (GCET) (affiliated with the University of the West of England (UWE), Bristol, U.K.). Since August 2018, he has been a Lecturer (Assistant Professor) with the University of Calgary. He has authored/coauthored more than 100 journal and conference publications. His current research interests include free-space optics (FSO), underwater communications, physical layer secrecy issues, full duplex systems, and secure D2D applications for 5G+ systems, among others.

KYUNG-SUP KWAK (Life Senior Member, IEEE) received the Ph.D. degree from the University of California. He was with Hughes Network Systems and the IBM Network Analysis Center, USA. He was with Inha University, South Korea, as a Professor. He was also the Dean of the Graduate School of Information Technology and Telecommunications and the Director of the UWB Wireless Communications Research Center. In 2008, he was an Inha Fellow Professor (IFP). His research interests include UWB radio systems, wireless body area networks and u-health networks, and nano and molecular communications. He is currently an Inha Hanlim Fellow Professor and also a Professor with the School of Information and Communication Engineering, Inha University. He is an active reviewer for various IEEE TRANSACTIONS and various other journals. He has been an active reviewer for various IEEE conferences. He was a recipient of an Exemplary Reviewer for IEEE TRANSACTIONS ON COMMUNICATIONS (TCOM) in 2018 and 2016, a recipient of an Exemplary Reviewer for IEEE WIRELESS COMMUNICATIONS LETTERS (WCL) in 2017 and 2014, a recipient of TAMEU ERCEN Research Excellence Award 2016, 2017, a recipient of a Recognized Reviewer Certificate by OSA Publishing in 2014, a recipient of Postdoctoral Research Award (PDRA) (first cycle) with Qatar National Research Foundation (QNRF) in 2014, a recipient of KAUST Academic Excellence Award (AEA) in 2014, and a recipient of IEEE Richard E. Mervin Student Scholarship Award in July 2013. He has co-organized the GRASNET’2016, 2017, 2018 workshops in conjunction with IEEE WCNC’2016, 2017 and IEEE GlobeCom 2018.

Dr. Ansari has been affiliated with IEEE and IET, since 2007. He has served in various capacities. He is serving on the IEEE Nominations and Appointments (N&A) Committee, during 2020–2021 and IEEE Communication Society Young Professionals (ComSocYP) Board, since April 2016. Since February 2017, he has been part of the IEEE 5G Tech Focus Publications Editorial Board. From October 2020 to September 2021, he was served as the Past-Chair for the IET Young Professionals Communities Committee (YPCC). From March 2016 to September 2020, he has served on the IET Satellites Technical Network (TN). He has served on the IET CC-EMEA (Communities Committee-Europe, Middle-East and Africa) for two complete terms from October 2015 to September 2018 and from October 2010 to September 2013. He is an active reviewer for various IEEE TRANSACTIONS and various other journals. He has served as a TPC for various IEEE conferences. He was a recipient of an Exemplary Reviewer for IEEE TRANSACTIONS ON COMMUNICATIONS (TCOM) in 2018 and 2016, a recipient of an Exemplary Reviewer for IEEE WIRELESS COMMUNICATIONS LETTERS (WCL) in 2017 and 2014, a recipient of TAMEU ERCEN Research Excellence Award 2016, 2017, a recipient of a Recognized Reviewer Certificate by OSA Publishing in 2014, a recipient of Postdoctoral Research Award (PDRA) (first cycle) with Qatar National Research Foundation (QNRF) in 2014, a recipient of KAUST Academic Excellence Award (AEA) in 2014, and a recipient of IEEE Richard E. Mervin Student Scholarship Award in July 2013. He has co-organized the GRASNET’2016, 2017, 2018 workshops in conjunction with IEEE WCNC’2016, 2017 and IEEE GlobeCom 2018.
