Abstract
A relevant category is a symmetric monoidal closed category with a diagonal natural transformation that satisfies some coherence conditions. Every cartesian closed category is a relevant category in this sense. The denomination relevant comes from the connection with relevant logic. It is shown that the category of sets with partial functions, which is isomorphic to the category of pointed sets, is a category that is relevant, but not cartesian closed.

Mathematics Subject Classification (2000): 03B47, 03F52, 03G30, 18D10, 18D15
Keywords: symmetric monoidal closed categories, diagonal natural transformation, intuitionistic relevant logic, partial functions, pointed sets

To the memory of Aleksandar Kron

1 Introduction

It is well known that the category of pointed sets with point-preserving functions as arrows is a symmetric monoidal closed category (see [5], Section IV.1). The symmetric monoidal closed structure in this category is provided by the smash product and internal hom-sets (see §3 below). This category, which is isomorphic to the category of sets with partial functions, has however a richer structure than just symmetric monoidal closed.
If to the assumptions for symmetric monoidal categories we add a diagonal
natural transformation with appropriate equations between arrows, then one ob-
tains a notion of monoidal category for which a coherence theorem is proved in
[10] with respect to relations on finite ordinals. We will call these categories rel-
evant monoidal categories, because the types of arrows in the relevant monoidal
category freely generated by a set of propositional letters corresponds to se-
quents in the multiplicative (i.e. intensional) conjunction (i.e. fusion) fragment
of relevant logic, including the multiplicative constant true proposition ⊤. This
fragment, which is the same both in intuitionistic and in classical versions of
relevant logic, catches essentially the structural rules of relevant logic, on which
the whole structure of this logic rests. The equations for relevant monoidal cat-
egories stem from [2]. (An incomplete set of these equations may be found in
[7], Definition 2.1(i).)

Symmetric monoidal closed categories that are also relevant monoidal with
respect to the same monoidal structure will be called relevant monoidal closed
categories. The relevant monoidal closed category RMC freely generated by
a set of propositional letters corresponds to the multiplicative conjunction-⊤-
implication fragment (both intuitionistic and classical) of relevant logic. We
have that A is the source and B the target of an arrow of RMC iff A → B
is a theorem of the multiplicative conjunction-⊤-implication fragment of the
relevant logic R (see [1], where multiplicative conjunction, i.e. fusion, is called
cotenability).

The category of pointed sets has a diagonal natural transformation with
respect to the smash product, which makes of it a relevant monoidal closed
category. Moreover, it has also finite products and coproducts (including the
empty ones), where product is different from the smash product. With this
additional structure, we obtain also operations corresponding to the additive
(lattice) connectives of relevant logic, without distribution of additive conjunc-
tion over additive disjunction. The relevant logic R has this distribution, but a
version of R without it also exists. (Linear logic lacks this distribution.) We are
still within a fragment of relevant logic common to its intuitionistic and classi-
cal versions. This fragment catches presumably the whole positive fragment of
intuitionistic relevant logic.

The connection between relevant logic and the category of pointed sets is
reminiscent of the connection that exists between intuitionistic logic and the
category Set of sets with functions. As intuitionistic propositional logic may be
identified with the bicartesian closed category (see [8], Section I.8) freely generated by a set of propositional letters, so the positive fragment of intuitionistic relevant logic may be identified with a free relevant category such as we will introduce. And as \( \text{Set} \) is the prime example of a bicartesian closed category, so the category of pointed sets may be the prime example of a relevant category.

Inspired by some ideas of Belnap, which are derived from Scott’s models for the untyped lambda calculus, Helman found in [6] that typed lambda terms in beta-normal form that code proofs in the additive conjunction-implication fragment of the relevant logic \( \mathbf{R} \) can be interpreted in the hierarchy of pointed sets with product and sets of point-preserving functions. A connection between relevant logic and the category of pointed sets was also investigated by Szabo in [12], but with an approach different from ours—in particular as far as distribution of product over coproduct is concerned. It was prefigured by Jacobs in [7] (Example 2.3(i)) that the category of pointed sets is a relevant monoidal category, though the notion of relevant monoidal category of that paper differs from ours.

2 Relevant categories

The objects of the category \( \textbf{SyMon} \) are the formulae of the propositional language \( \mathcal{L}_{\top,\land} \), generated from a set \( \mathcal{P} \) of propositional letters with the nullary connective, i.e. propositional constant, \( \top \) and the binary connective \( \land \). We use \( p, q, r, \ldots \), sometimes with indices, for propositional letters, and \( A, B, C, \ldots \), sometimes with indices, for formulae. As usual, we omit the outermost parentheses of formulae and other expressions later on.

To define the arrows of \( \textbf{SyMon} \), we define first inductively a set of expressions called the arrow terms. Every arrow term of \( \textbf{SyMon} \) will have a type, which is an ordered pair of formulae of \( \mathcal{L}_{\top,\land} \). We write \( f: A \vdash B \) when the arrow term \( f \) is of type \((A, B)\). (We use the turnstile \( \vdash \) instead of the more usual \( \rightarrow \), which we reserve for a connective and a biendofunctor.) We use \( f, g, h, \ldots \), sometimes with indices, for arrow terms.

For all formulae \( A, B \) and \( C \) of \( \mathcal{L}_{\top,\land} \) the following primitive arrow terms:

\[
\begin{align*}
\mathbf{1}_A &: A \vdash A, \\
\mathbf{b}^{\top}_{A,B,C} &: A \land (B \land C) \vdash (A \land B) \land C, \\
\mathbf{b}^\land_{A,B,C} &: (A \land B) \land C \vdash A \land (B \land C), \\
\mathbf{c}_{A,B} &: A \land B \vdash B \land A,
\end{align*}
\]
are arrow terms of \textbf{SyMon}. If \( g: A \vdash B \) and \( f: B \vdash C \) are arrow terms of \textbf{SyMon}, then \( f \circ g: A \vdash C \) is an arrow term of \textbf{SyMon}; and if \( f: A \vdash D \) and \( g: B \vdash E \) are arrow terms of \textbf{SyMon}, then \( f \land g: A \land B \vdash D \land E \) is an arrow term of \textbf{SyMon}. This concludes the definition of the arrow terms of \textbf{SyMon}.

Next we define inductively the set of equations of \textbf{SyMon}, which are expressions of the form \( f = g \), where \( f \) and \( g \) are arrow terms of \textbf{SyMon} of the same type. We stipulate first that all instances of \( f = f \) and of the following equations are equations of \textbf{SyMon}:

\[
\begin{align*}
\text{(cat 1)} & \quad f \circ 1_A = 1_B \circ f: A \vdash B, \\
\text{(cat 2)} & \quad h \circ (g \circ f) = (h \circ g) \circ f, \\
\text{(\& 1)} & \quad 1_A \land 1_B = 1_{A \land B}, \\
\text{(\& 2)} & \quad (g_1 \circ f_1) \land (g_2 \circ f_2) = (g_1 \land g_2) \circ (f_1 \land f_2),
\end{align*}
\]

for \( f: A \vdash D \), \( g: B \vdash E \) and \( h: C \vdash F \),

\[
\begin{align*}
\text{(\hat{b} \rightarrow \text{nat})} & \quad ((f \land g) \circ h) \circ \hat{b}_{A,B,C} = \hat{b}_{D,E,F} \circ (f \land (g \circ h)), \\
\text{(\hat{c} \rightarrow \text{nat})} & \quad (g \land f) \circ \hat{c}_{A,B} = \hat{c}_{D,E} \circ (f \land g), \\
\text{(\hat{\delta} \rightarrow \text{nat})} & \quad f \circ \hat{\delta}_{A} = \hat{\delta}_{B} \circ (f \land 1_T), \\
\text{(\hat{b} b)} & \quad \hat{b}_{A,B,C} = \hat{b}_{A,B,C} = 1_{(A \land B) \land C}, \\
\text{(\hat{b} 5)} & \quad \hat{b}_{A,B,C,D} = \hat{b}_{A,B,C,D} = 1_{A \land (B \land C \land D)}, \\
\text{(\hat{c} c)} & \quad \hat{c}_{A,B} = \hat{c}_{A,B} = 1_{A \land B}, \\
\text{(\hat{b} c)} & \quad \hat{c}_{A,B \land C} = \hat{c}_{B,C} = 1_{B \land C}, \\
\text{(\hat{\delta} \delta)} & \quad \hat{\delta}_{A} = \hat{\delta}_{A} = 1_{A \land T}, \\
\text{(\hat{b} \delta)} & \quad \hat{b}_{A,B,T} = \hat{b}_{A,B,T} = 1_{A \land B}.
\end{align*}
\]

The set of equations of \textbf{SyMon} is closed under symmetry and transitivity of equality and under the rules

\[
\begin{align*}
\text{(cong \ \xi)} & \quad \begin{array}{c}
\frac{f = f_1 \quad g = g_1}{f \xi g = f_1 \xi g_1}
\end{array}
\]

\]
where $\xi \in \{ \ast, \land \}$; if $\xi = \ast$, then $f \ast g$ is defined (namely, $f$ and $g$ have appropriate, composable, types), and analogously for $f_1 \ast g_1$. This concludes the definition of the equations of $\textbf{SyMon}$.

On the arrow terms of $\textbf{SyMon}$ we impose the equations of $\textbf{SyMon}$. This means that an arrow of $\textbf{SyMon}$ is an equivalence class of arrow terms of $\textbf{SyMon}$ defined with respect to the smallest equivalence relation such that the equations of $\textbf{SyMon}$ are satisfied (see [4], Section 2.3, for details).

The equations $(\land 1)$ and $(\land 2)$ say that $\land$ is a biendofunctor (a $2$-endofunctor, in the terminology of [4], Section 2.4). Equations with "nat" in their names, like those in the list above, say that $\hat{b} \hat{c}$, $\hat{c}$, etc. are natural transformations.

The category $\textbf{SyMon}$ is the free symmetric monoidal category in the sense of [9] (Chapter VII) generated by the set $P$.

The category $\textbf{ReMon}$ is defined as the category $\textbf{SyMon}$ with the following additions. We have the additional primitive arrow terms

$$\hat{w}_A : A \vdash A \land A,$$

and the following additional equations:

$$(\hat{w} \text{ nat}) \quad (f \land f) \ast \hat{w}_A = \hat{w}_D \ast f,$$

$$(\hat{b} \hat{w}) \quad \hat{b}_{A,A,A} \ast (1_A \land \hat{w}_A) \ast \hat{w}_A = (\hat{w}_A \land 1_A) \ast \hat{w}_A,$$

$$(\hat{c} \hat{w}) \quad \hat{c}_{A,A} \ast \hat{w}_A = \hat{w}_A,$$

for $\hat{c}_{A,B,C,D} = df \hat{b}_{A,C,B \land D} \ast (1_A \land (\hat{b}_{B,C,B,D} \ast (\hat{c}_{B,C} \land 1_D) \ast \hat{b}_{B,C,D})) \ast \hat{b}_{A,B,C \land D} :$

$$(A \land B) \land (C \land D) \vdash (A \land C) \land (B \land D),$$

$$(\hat{b} \hat{c} \hat{w}) \quad \hat{w}_{A \land B} = \hat{c}_{A,A,B,B} \ast (\hat{w}_A \land \hat{w}_B),$$

$$(\hat{w} \check{\delta}) \quad \check{\delta}_\top = \hat{w}_\top.$$

(These equations may be found in [2]; they are also in [7], Definition 2.1(i), but with $(\hat{b} \hat{c} \hat{w})$ lacking.)

A relevant monoidal category is a symmetric monoidal category that has in addition a natural transformation $\hat{w}$ that satisfies the equations of $\textbf{ReMon}$. The category $\textbf{ReMon}$ is the free relevant monoidal category generated by the set $P$. A coherence theorem is proved for this category in [10] with respect to the category whose arrows are relations between finite ordinals. This means that there is a faithful functor from $\textbf{ReMon}$ into the latter category.
The category SMC is defined as the category SyMon with the following additions. We have an additional binary connective \( \to \), and the additional primitive arrow terms

\[ \epsilon_{A,B} : A \land (A \to B) \vdash B, \quad \eta_{A,B} : B \vdash A \to (A \land B); \]

on arrow terms we have the additional unary operations \( A \to \), for every object \( A \), such that for \( f : B \vdash C \) we have the arrow term \( A \to f : A \to B \vdash A \to C \).

The equations of SMC are obtained by assuming the following additional equations:

\[(A \to 1) \quad A \to 1_B = 1_{A \to B}, \]
\[(A \to 2) \quad A \to (f \circ g) = (A \to f) \circ (A \to g), \]
\[(\varepsilon \text{ nat}) \quad f \circ \varepsilon_{A,B} = \varepsilon_{A,C} \circ (1_A \land (A \to f)); \]
\[(\eta \text{ nat}) \quad (A \to (1_A \land f)) \circ \eta_{A,B} = \eta_{A,C} \circ f; \]
\[(\varepsilon \eta \land) \quad \varepsilon_{A,A \land B} \circ (1_A \land \eta_{A,B}) = 1_{A \land B}; \]
\[(\varepsilon \eta \to) \quad (A \to \varepsilon_{A,B}) \circ \eta_{A,A \to B} = 1_{A \to B}; \]

and the following additional rule:

\[
\begin{align*}
\frac{f = g}{A \to f = A \to g}
\end{align*}
\]

The equations \((A \to 1)\) and \((A \to 2)\) say that \( A \to \) is a functor, while \((\varepsilon \eta \land)\) and \((\varepsilon \eta \to)\) are the triangular equations of an adjunction (see [9], Section IV.1).

The category SMC is the free symmetric monoidal closed category generated by the set \( \mathcal{P} \) (see [9], Section VII.7).

The category RMC is defined by combining the definitions of ReMon and SMC. Relevant monoidal closed categories are symmetric monoidal closed categories that are also relevant monoidal with respect to the same monoidal structure. The category RMC is the free relevant monoidal closed category generated by the set \( \mathcal{P} \).

A positive intuitionistic relevant category is a relevant monoidal closed category that has all finite products and coproducts (including the empty ones).
3 The category of pointed sets

3.1 The category of pointed sets $\text{Set}_*$ is the category whose objects are sets with a distinguished element $*$, and whose arrows are functions $f$ such that $f(*) = *$. This category is isomorphic to the category of sets with partial functions, i.e. relations that are single-valued, but not necessarily defined on the whole domain.

We have the following special objects and operations on objects in $\text{Set}_*$:

$$I = \{*\}, \quad a' = \{(x, *) \mid x \in a - I\}, \quad b'' = \{(*, y) \mid y \in b - I\},$$
$$a \otimes b = (\{(a - I) \times (b - I)\} \cup I),$$
$$a \boxtimes b = (a \otimes b) \cup a' \cup b'',$$
$$a \boxplus b = a' \cup b'' \cup I.$$

Let $\top$ in $\text{Set}_*$ be $I \cup \{x\}$, where $x \neq *$, and let $\land \equiv \otimes$, which is the smash product. For $a$ and $b$ objects of $\text{Set}_*$, let $a \to b$ be the union of $I$ with the set of arrows of $\text{Set}_*$ from $a$ to $b$ without the arrow with constant value $*$. It is well known that with these operations on objects $\text{Set}_*$ is a symmetric monoidal closed category (see [5], Section IV.1; see [3], Section 6, for more details). The importance of $\text{Set}_*$ for checking equations between arrows in SMC is demonstrated by Soloviev in [11].

It can also be easily shown that with $\hat{w}_a(x)$ being $(x, x)$ for $x \neq *$, and $*$ otherwise, $\text{Set}_*$ is a relevant monoidal closed category. It was prefigured in [7] (Example 2.3(i)) that $\text{Set}_*$ is a relevant monoidal category, though the notion of relevant monoidal category of that paper differs from ours, as explained in the preceding section.

We also have arrows of the type of projections for the smash product, which are defined in an obvious way, but these arrows do not make natural transformations. The category $\text{Set}_*$ is not a cartesian category with the smash product. But $\text{Set}_*$ is a bicartesian category (i.e. a category with all finite products and coproducts) with binary product being $\boxtimes$ (which corresponds to cartesian product) and binary coproduct being $\boxplus$, while $I$ is both the terminal and the initial object, i.e. the empty product and coproduct. It is shown in [4] (Sections 9.7, 12.4 and 13.4) that $\text{Set}_*$ is a bicartesian category of a particular kind, called there zero-dicartesian.

So $\text{Set}_*$ is a positive intuitionistic relevant category in the sense of the preceding section.
3.2 In [3] one can find a characterization of the objects isomorphic in SMC, and hence also in every symmetric monoidal closed category. Two objects $A$ and $B$ of SMC are isomorphic iff one can derive $A = B$ in the equational calculus $S$ whose axioms are the axioms of commutative monoids with respect to $\land$ and $\top$ and the following two equations:

$$\top \to C = C,$$

$$(A \land B) \to C = B \to (A \to C).$$

The proof of this equivalence in [3] is based on a proof of an analogous equivalence where SMC is replaced by $\text{FinSet}_\ast$, which is the category of finite pointed sets with point-preserving functions (a full subcategory of $\text{Set}_\ast$), and $A$ and $B$ are diversified, which means that no propositional letter occurs more than once in these formulae. The equational calculus $S$ axiomatizes all the equations between diversified formulae that hold in natural numbers, where formulae are understood as arithmetical terms such that propositional letters are variables ranging over natural numbers, $\top$ is 1, the operation $\land$ is multiplication, and $m \to n$ is $(n+1)^m-1$.

We conjecture that these two assertions concerning $S$, its arithmetical interpretation and $\text{FinSet}_\ast$ are also true when the restriction to diversified formulae is lifted. If this conjecture were true, then the calculus $S$ would characterize not only all the formulae isomorphic in SMC, but also in $\text{RMC}$.
