**Introduction**

Metal–organic frameworks (MOFs) or porous coordination polymers have emerged as a new type of porous materials with regular arrays of metal ions, or metal clusters and organic linkers. Because the pore sizes can be finely tuned and the functional sites can be deliberately immobilized on the pore surfaces, MOFs have unique properties and wide applications in gas storage, molecule separation, chemical sensing, catalysis, and drug delivery. Among them, gas storage concerning H2, CO2, and CH4 is the most investigated in recent years.2–6 The NOTT-MOFs synthesized by the Schröder group, as a common polar functional group, has been proved effective in some cases in the adsorption of gases like CO2 and hydrocarbon.7–9 Inspired by these works, herein we designed a new type of MOF, which enables these MOFs great structural variability, which causes difficulties in property optimization. Therefore, a stable structural platform for isoreticular optimization is of great importance. PCN-306, as a rare MOF with [3,3,4,4]-connected mfj-type network, represents a suitable structural prototype for further tailoring among MOFs constructed by V-shaped tetracarboxylic ligands.10 Our previous work on NJU-Bai10, an analogue of PCN-306, exhibits high hydrogen uptake and high methane storage property.11

In order to achieve high performance of gas adsorption in MOFs, isoreticular optimization based on a stable structural platform by ligand functionalization is widely applied. Among them, polar functional groups are most preferred. Methoxy group, as a common polar functional group, has been proved effective in some cases in the adsorption of gases like CO2 and hydrocarbon.10–12 Inspired by these works, herein we designed and incorporated the bulky methoxy groups (Scheme 1) into the framework of PCN-306 to form an another mfj-type MOF [Cu6(MBDPB)3(H2O)6]·12DMF·10H2O (NJFU-3, NJFU for Nanjing Forestry University; MBDPB for 5-methoxyl-1,3-bis(3,5-dicarboxyphenyl)benzene) was successfully synthesized and structurally characterized. With moderately high porosity, appropriate pore aperture and unsaturated metal sites, the activated NJFU-3 exhibits high H2 (2.56 wt% at 77 K and 1 bar) and CO2 uptakes (15.8 wt% at 298 K and 1 bar), and a moderately high CH4 storage capacity of 155 cm3 cm−3 at 35 bar and 298 K. Meanwhile, it shows a comparably high delivery amount of 135 cm3 cm−3 when taking 5 bar as a specific lower pressure limit and 65 bar as the upper limit.

Based on a new V-shaped tetracarboxylic ligand with a methoxyl group, a new mfj-type microporous metal–organic framework [Cu6(MBDPB)3(H2O)6]·12DMF·10H2O (NJFU-3, NJFU for Nanjing Forestry University; MBDPB for 5-methoxyl-1,3-bis(3,5-dicarboxyphenyl)benzene) was successfully synthesized and structurally characterized. With moderately high porosity, appropriate pore aperture and unsaturated metal sites, the activated NJFU-3a exhibits high H2 (2.56 wt% at 77 K and 1 bar) and CO2 uptakes (15.8 wt% at 298 K and 1 bar), and a moderately high CH4 storage capacity of 155 cm3 cm−3 at 35 bar and 298 K. Meanwhile, it shows a comparably high delivery amount of 135 cm3 cm−3 when taking 5 bar as a specific lower pressure limit and 65 bar as the upper limit.

**A new mfj-type metal–organic framework constructed from a methoxyl derived V-shaped ligand and its H2, CO2 and CH4 adsorption properties**

Liting Du, Zhiyong Lu, Li Xu and Jinchi Zhang

Based on a new V-shaped tetracarboxylic ligand with a methoxyl group, a new mfj-type microporous metal–organic framework [Cu6(MBDPB)3(H2O)6]·12DMF·10H2O (NJFU-3, NJFU for Nanjing Forestry University; MBDPB for 5-methoxyl-1,3-bis(3,5-dicarboxyphenyl)benzene) was successfully synthesized and structurally characterized. With moderately high porosity, appropriate pore aperture and unsaturated metal sites, the activated NJFU-3a exhibits high H2 (2.56 wt% at 77 K and 1 bar) and CO2 uptakes (15.8 wt% at 298 K and 1 bar), and a moderately high CH4 storage capacity of 155 cm3 cm−3 at 35 bar and 298 K. Meanwhile, it shows a comparably high delivery amount of 135 cm3 cm−3 when taking 5 bar as a specific lower pressure limit and 65 bar as the upper limit.
NJFU-3a exhibits a high hydrogen adsorption of 2.56 wt% at 77 K and 1 bar and a high CO₂ uptake of 15.8 wt% at 298 K and 1 bar. Meanwhile, it shows a moderately high CH₄ storage of 155 cm³ cm⁻³ at 35 bar and 298 K and a quite large CH₄ delivery amount of 135 cm³ cm⁻³, which indicates it as a potential material for CH₄ storage.

Experimental

Materials and methods

All chemical reagents were obtained from commercial sources and, unless otherwise noted, were used as received without further purification. Elemental analyses (C, H, and N) were performed on a Perkin-Elmer 240 analyzer. The IR spectra were recorded in the 400–4000 cm⁻¹ range on a Bruker VERTEX 80V spectrometer using KBr pellets. 1H NMR spectra were recorded on a Bruker DRX-500 spectrometer with tetramethylsilane as an internal reference. Thermal gravimetric analyses (TGA) were performed under N₂ atmosphere (100 mL min⁻¹) with a heating rate of 5 °C min⁻¹ using a 2960 SDT thermogravimetric analyzer. Powder X-ray diffraction (PXRD) data were collected on a Bruker D8 ADVANCE X-ray diffractometer with Cu/Kz radiation.

Gas sorption measurements

Low pressure gas sorption measurements were conducted using a Micromeritics ASAP 2020 surface area and pore size analyzer up to saturated pressure at different temperatures. High pressure gravimetric CH₄ adsorption measurements were performed on an ISOSORP HyGpra + V adsorption analyzer (Rubotherm, Germany) over 0–65 bar range at 298 K. Before the gas sorption measurement, more than 150 mg (about 100 mg pure bulk sample) were loaded into a sample tube, and the samples were allowed to soak for 3 days for solvent-exchange. During this period, methanol was refreshed every 8 hours. A fresh anhydrous methanol was then added, and the samples were allowed to soak for 3 days for solvent-exchange. After then, the sample was charged into a sample tube and activated at 90 °C for 20 hours under vacuum.

X-ray collection and structure determination

Single crystal suitable for X-ray structure determination were selected and sealed in a capillary under a microscope. The X-ray diffraction intensity data were measured on a BRUKER D8 VENTURE PHOTON diffractometer at room temperature using graphite monochromated Mo/Kz radiation (λ = 0.71073 Å).

Results and discussion

The structure of NJFU-3 was characterized by single-crystal X-ray diffraction measurement, and the phase purity of the bulk material was independently confirmed by powder X-ray diffraction (PXRD). The similarity of the simulated PXRD pattern from single-crystal data to those for both as-synthesized and activated samples reveals that the single crystal is representative of the pure bulk sample, and the framework is robust and its crystallinity can be retained after the removal of guest molecules and the coordinated water molecules (Fig. S1, ESIF†). Single-crystal structure determination reveals that NJFU-3 crystallizes in orthorhombic space group Cmc2₁, and the symmetric unit consists of one and a half MBDPB-ligand, three crystallographically Cu⁺ ions and three coordinated water molecule (Fig. S2†). Two types of MBDPB-ligands existed in the structure possess

† Crystal data for NJFU-3: C₃₇H₃₂Cu₂O₁₆, M = 1774.28, orthorhombic, Cmc2₁, a = 24.742(3) Å, b = 33.475(3) Å, c = 18.462(19) Å, α = β = γ = 90°, V = 15 291 (3) Å³, Z = 4, D₀ = 0.771 g cm⁻³, GOF = 0.984 based on F², final R₁ = 0.0729, wR₂ = 0.1842 [for 18 616 data I > 2σ(I)]; data for structure was treated with squeeze.
different dihedral angles between central and terminal benzene rings, one (Fig. 1a) with about 43.4° and 35.6° and the other (Fig. 1b) approximately 63.4° and 63.4°. Each MBDPB-ligand links with four 4-connected dicopper paddlewheel SBUs. By simplifying MBDPB-ligands as two 3-connected nodes and regarding the dicopper paddlewheels SBUs as 4-connected nodes, the whole structure adopts a (3,3,4,4)-c 4-nodal topology (Fig. 1c). Just as its isoreticular analogues, there are two types of cages existed in the structure: one is surrounded by seven dicopper SBUs and eleven MBDPB-ligands (Cage A, Fig. 2a), and the other is assembly by eleven dicopper SBUs and eleven MBDPB-ligands (Cage B, Fig. 2b). The cavity inside Cage A and Cage B is with diameters of about 11 Å (excluding van der Waals radii) and 12 Å, respectively. The inner cavity of NJFU-3 endows it high porosity, as calculated using PLATON routine, with the solvent accessible volume of 74.1% in the dehydrated structure of NJFU-3.

Its permanent porosity as well as gas adsorption properties was further investigated. The phase purity of the bulk sample was confirmed by powder X-ray diffraction (PXRD) (Fig. S1, ESI†) and a weight loss of about 41% at 30–300 °C was observed from the TG curve of NJFU-3, which corresponds to 12 DMF and 16·H2O molecules (calcd 41.1%) (Fig. S11, ESI†). The methanol solvent-exchanged sample was degassed under high vacuum at 90 °C for 20 hours to obtain the fully activated sample NJFU-3a. A color change from pale-blue to deep-purple-blue occurred, indicating the exposure of unsaturated metal sites in NJFU-3a. The type-I isotherm of N2 adsorption at 77 K indicates that NJFU-3a is a microporous material. Based on the N2 adsorption isotherm, the Brunauer–Emmett–Teller (BET) surface area and Langmuir surface area of NJFU-3a are calculated to be 2531.1 m² g⁻¹ and 2671.9 m² g⁻¹, respectively. The total pore volume obtained from N2 isotherm is 0.94 cm³ g⁻¹.

The moderately high surface area, large pore volume and unsaturated metal sites within the structure of NJFU-3a encouraged us to study its gas adsorption capacity. Low-pressure hydrogen adsorption measurements of NJFU-3a were performed at 77 K and 87 K. The adsorption isotherms are fully reversible (Fig. S5†), and 2.56 wt% of H2 uptake for NJFU-3a was observed under the condition of 77 K and 1 bar, which is a bit higher than that of PCN-306 (ref. 34) (2.50 wt%) (Fig. 3b). Meanwhile, the H2 uptake of NJFU-3a is also higher than that of most of the NOTT-series MOFs constructed by linear tetra-carboxylic ligands, such as NOTT-101 (ref. 22) (2.46 wt%), NOTT-109 (ref. 22) (2.28 wt%), NOTT-106 (ref. 22) (2.24 wt%), making it one of the MOFs with highest H2 uptake capacity at 77 K and 1 bar. The CO2 adsorption property of NJFU-3a was also measured at 273 K and 298 K. As shown in Fig. 3c, at 298 K and 1 bar, NJFU-3a can absorb 95.6 cm³ g⁻¹ (or 15.8 wt%) of CO2, which is the highest among all the mff-MOFs such as PCN-306 (ref. 34) (13.8 wt%) and PCN-308 (ref. 34) (15.4 wt%), and is also higher than some well-known MOFs with open metal sites and/or Lewis basic sites, such as en-CuBTTri (ref. 40) (5.5 wt%), MOF-505 (ref. 41) (14.4 wt%), Bio-MOF-1 (ref. 42) (14.3 wt%), SNU-21S (11.1 wt%), PCN-61 (ref. 14 and 44) (13.9 wt%), PCN-68 (ref. 14 and 44) (4.84 wt%), MIL-102 (ref. 45) (13.6 wt%), MAF-X7 (ref. 46) (5.13 wt%) and NU-100 (ref. 47) (12 wt%). To

**Fig. 2** Two types of cages in NJFU-3: Cage A (purple) and Cage B (orange).

![Fig. 3](image3.png)  
**Fig. 3** (a) N2 adsorption isotherm of NJFU-3a at 77 K; (b) H2 adsorption isotherms of NJFU-3a at 77 K and 87 K; (c) CO2 adsorption isotherms of NJFU-3a at 273 K and 298 K; (d) CO2 and H2 adsorption enthalpies of NJFU-3a.
further understand the interaction between gases molecules and the framework, we calculated the H₂ and CO₂ adsorption enthalpies of NJFU-3a by virial method, and the zero-coverage values are 6.27 kJ mol⁻¹ and 24.0 kJ mol⁻¹ for H₂ and CO₂ respectively. Compared with those of the PCN-306, the analogue without methoxyl group, no obvious change was found (H₂: 6.37 kJ mol⁻¹; CO₂: 23.997 kJ mol⁻¹). Therefore, the existence of methoxyl groups in NJFU-3a does not contribute to the enhancement of interactions between gas molecules and framework, but optimizes the inner textural property that leads to the improvement of gas adsorption property at 1 bar. Furthermore, the CH₄ adsorption isotherm of NJFU-3a at 273 K (Fig. S9, ESI†) was also measured to investigate the influence of methoxyl group on CO₂/CH₄ selectivity. By applying the Ideal Adsorbed Solution Theory (IAST), the CO₂/CH₄ selectivity of NJFU-3a was predicted to be 7.9 (Fig. S9†), which is a bit higher than that of PCN-306 (7.52). Although not significant, such improvement still indicates the positive effect of methoxyl groups on the selective adsorption of CO₂ in this type of MOF.

We further measured the CH₄ storage capacity of NJFU-3a at 298 K. As shown in Fig. 4b, NJFU-3a shows moderately high volumetric methane uptakes of 155 cm³ cm⁻³ under 35 bar and 298 K, reaching approximately 86% of the DOE standard (180 cm³ cm⁻³) at 35 bar and room temperature. The methane storage capacity of NJFU-3a is lower than some of the MOFs with extraordinary high methane storage, but higher than most MOFs materials under similar condition (MOF-5, 150 cm³ cm⁻³; PCN-80, 110 cm³ cm⁻³; ZJU-36, 142 cm³ cm⁻³; NU-111, 138 cm³ cm⁻³; PCN-66, 136 cm³ cm⁻³; UiO-66 (Zr), 146 cm³ cm⁻³; MOF-205, 119 cm³ cm⁻³). When the pressure reaches 65 bar, the methane storage capacity of NJFU-3a increases up to 189 cm³ cm⁻³. Taking 5 bar as a specific lower pressure limit and 65 bar as the upper limit, the methane delivery amounts of NJFU-3a is 135 cm³ cm⁻³, that is, a tank filled with NJFU-3a can deliver 51.3% as much fuel as the CNG tank operating at the same lower pressure limit and at 250 bar as the upper limit. Although this value is lower compared to the best performing MOFs, it is still quite comparable with MgMOF-74 (ref. 8) (142 cm³ cm⁻³), NiMOF-74 (ref. 8) (142 cm³ cm⁻³), CoMFO74 (ref. 8) (136 cm³ cm⁻³), NOTT-100 (ref. 24) (139 cm³ cm⁻³), and higher than NOTT-119 (ref. 51) (134 cm³ cm⁻³), MOF-210 (ref. 1) (131 cm³ cm⁻³), DUT-4 (ref. 52) (124 cm³ cm⁻³), ZJU-32 (ref. 53) (120 cm³ cm⁻³), MOF-200 (ref. 1) (106 cm³ cm⁻³), indicating NJFU-3a as a potential material for CH₄ storage.

**Conclusions**

In summary, we have developed a new organic linker of the V-shaped tetracarboxylic ligand with methoxyl group, and investigated the gases adsorption of the three-dimensional metal–organic framework. The activated NJFU-3a exhibits moderate high porosity with the BET surface area of 2531.1 m² g⁻¹. Due to the unsaturated metal sites, suitable pore aperture and moderate high permanent porosity, NJFU-3a exhibits a high H₂ adsorption of 2.56 wt% at 77 K and 1 bar and a high CO₂ uptake of 15.8 wt% at 298 K and 1 bar. Meanwhile, a moderately high CH₄ storage of 155 cm³ cm⁻³ at 35 bar and 298 K and a comparably high delivery amount of 135 cm³ cm⁻³ was also observed in NJFU-3a when taking 5 bar as a specific lower pressure limit and 65 bar as the upper limit.
