Corrolazine macrocycle in soluble P\textsuperscript{V} complex of N-methylated 2-pyridyl substituted derivative \([(\text{Me}^+\text{Py})_8\text{CAP(OH)}_2]\) can be reduced reversibly by dithionite affording consecutively anion-radical \([(\text{Me}^+\text{Py})_8\text{CAP(OH)}_2]^\text{−}\) and \(\pi\)-dianion \([(\text{Me}^+\text{Py})_8\text{CAP(OH)}_2]^\text{2−}\). Treatment of \([(\text{Me}^+\text{Py})_8\text{CAP(OH)}_2]\) with super-reduced cobalamin \([\text{Cbl(I)}]\) leads directly to \(\pi\)-dianion, which can reduce aquacobalamin \([(\text{H}_2\text{O})\text{Cbl(III)}]\). The central dihydroxophosphonate moiety in \([(\text{Me}^+\text{Py})_8\text{CAP(OH)}_2]\) undergoes two-stage acid ionization in basic medium.

Keywords: Water soluble corrolazines, acid-base interaction, dithionite, cobalamins, ox-red reactions.

Водорастворимый P\textsuperscript{V} комплекс N–метилированного окта(2–пирридил)корролазина: окислительно–восстановительные реакции с дитионитом натрия и кобаламинами

Водорастворимый комплекс фосфора(V) с N-метилированным 2-пирридилзамещенным корролазином \([(\text{Me}^+\text{Py})_8\text{CAP(OH)}_2]\) обратимо восстанавливается дитионитом натрия в щелочной среде, последовательно образуя анион-радикал \([(\text{Me}^+\text{Py})_8\text{CAP(OH)}_2]^\text{−}\) и \(\pi\)-динаон \([(\text{Me}^+\text{Py})_8\text{CAP(OH)}_2]^\text{2−}\). При взаимодействии с супер-восстановленной формой кобаламина \([\text{Cbl(I)}]\) сразу же образуется \(\pi\)-динаон, который восстанавливает акваcobаламин \([(\text{H}_2\text{O})\text{Cbl(III)}]\). Центральный дигидроксофосфонатный фрагмент подвергается кислотной ионизации в щелочной среде.

Keywords: Водорастворимые корролазины, кислотно-основное взаимодействие, дитионит, кобаламини, окислительно-восстановительные реакции.
Corrolazines (CA) are analogs of porphyrinases (PA) containing contracted macroheterocycle consisting of dipyrryl fragment, one pyrrole and one pyrrolenine rings joined by three bridging meso-nitrogen atoms (Chart 1).\cite{1,2} Complexes of corrolazines containing \( P^V \) as a central atom are easily available by reaction of the corresponding metal free porphyrines with phosphorus(III) halides in pyridine. In such way the corresponding \( P^V \) corrolazines were obtained from variously substituted phthalocyanines,\cite{3} tetrapyrazinoporphyrazines\cite{4} and aryl substituted porphyrazines.\cite{5} The contraction of the porphyrin macrocycle requires the reductive conditions, and complexes of tetrabenzo fused corrolazines (TBCA) with Si\( ^{III} \), Ge\( ^{III} \), Al\( ^{III} \) and Ga\( ^{III} \) can be prepared from the corresponding metal phthalocyanines in the presence of reductants (NaBH\( _4 \), Mg/Alk\( _3 \)SiCl).\cite{6–9} Non-metalated TBCA and its complexes with other metals are not-known, but \( P^V \) complexes of octaaryl substituted corrolazines can be reductively dephosphorylated (Na/NH\( _4 \) in THF)\cite{10,11} and converted to the transition metal complexes – an effective catalysts in oxidation reactions.\cite{12} The reduction processes involving corrolazines as reactants or products were studied only in non-aqueous solvents. Among water soluble corrolazines only tetrasulfonated tetrabenzocorrolazine was so far reported.\cite{11,12} It was found that sulfonated \( P^V \) tetrabenzocorrolazine due to its enhanced abilities to generate \( \cdot O_2 \)\cite{13} and to cleave DNA\cite{14} is a perspective dye for medical applications, e.g. as photosensitizer for photodynamic therapy.

Taking these issues into account the study of interaction of \( P^V \) corrolazines in aqueous media with various reducing agents including natural reductants is of great interest. Sodium dithionate is a strong S-containing reductant which is capable to reduce cobalamin\( ^{[15]} \) – derivatives of the vitamin B\( _12 \) which play an important role in the natural biochemical processes as redox catalysts.\cite{16} While cobalamin [Cbl(III)] contains Co\( ^{III} \) in the coordination center of the corrin macrocyclic ligand, Co\( ^{II} \) and Co\( ^{I} \) are present in its reduced and super-reduced forms, [Cbl(II)] and [Cbl(I)], respectively. The catalytic cycle of aqua- and cyanocobalamin involve the reversible reduction of the central metal Co\( ^{III} \) ↔ Co\( ^{II} \) ↔ Co\( ^{I} \). The reduced forms of cobalamin catalyzing the reduction of oxygen and reactive oxygen species\cite{[18,19]} can therefore modulate the PDT activity of the photosensitizer.

We have prepared novel water soluble photosensitizer – \( N \)-methylated derivative of 2-pyridyl substituted \( P^V \) corrolazine [(Me\( ^+ \)Py\( _8 \)CaP(OH)\( _3 \))(I\( _8 \))\( P(OH)\_2 \)]. We have used similar reaction conditions\cite{13} for preparation of 2-pyridyl substituted \( P^V \) corrolazine from the corresponding porphyrin, [Py\( _8 \)P4H\( _4 \)], obtained as described earlier\cite{13,21} and PBr\( _3 \), (1:20 molar ratio). The crude \( P^V \) corrolazine obtained as precipitate by pouring of the reaction mixture into water was dissolved in CH\( _2 \)Cl\( _2 \), passed through silica column. The residue obtained after evaporation of the solvent was treated with ~ 4-fold excess of methyl iodide in CH\( _2 \)Cl\( _2 \), passed through silica column. The residue obtained after evaporation of the solvent was treated with ~ 4-fold excess of methyl iodide in

**Scheme 1.** Synthesis of \( N \)-methylated 2-pyridyl substituted \( P^V \) corrolazine
DMF in conditions similar to that used for N-methylation of 2-pyridyl substituted porphyrines.\cite{22,23} After mixing with toluene and staying in the refrigerator N-methylated P\textsuperscript{V} corrolazine [(Me\textsuperscript{+}Py\textsubscript{8}CA\textsubscript{P}(OH)\textsubscript{2}] was obtained as green iodide salt. It is well soluble in water and its \textsuperscript{31}P NMR spectrum recorded in D\textsubscript{2}O contains the resonance signal at \textasciitilde205 ppm, which is typical for hexacoordinated P\textsuperscript{V} atom strongly shielded by \textpi-ring current of the aromatic macrocycle.\cite{24} Electronic absorption spectrum of the neutral water solution contains an intense Q band at 660 nm and Soret band at 457 nm (Figure 1A, curve 2). Appearance of the Soret band at 440–460 nm is a typical feature confirming formation of corrolazine macrocycle, since in the corresponding porphyrine complexes the maximum of this band is observed at 350–380 nm. It is interesting that position of the Q band maxima in the absorption spectra depends on the pH of water solutions. The maximum of Q band observed at 660 nm in the neutral medium (pH = 7.5), is shifted hypsochromically to 650 nm upon acidification (at pH = 4.0) and bathochromically to 680 nm upon increase of pH >9 (Figure 1A, curves 1 and 3). These spectral changes are very likely connected with acid ionization of the central dihydrophosphonate moiety:

\[
\begin{align*}
(P(OH)\textsubscript{2}) & \xrightarrow{H^+} (P(O^-)(OH)) \\
(P(O^-)(OH)) & \xrightarrow{H^+} (P(O\textsuperscript{2-})\textsubscript{2})
\end{align*}
\]

It is interesting that fluorescence intensity strongly depends on pH and is practically completely quenched in basic medium (Figure 1B). Quenching of fluorescence can be explained by intramolecular electron transfer from the negatively charged oxygen atom in the anionic forms appearing in the basic media.

The addition of Na\textsubscript{2}S\textsubscript{2}O\textsubscript{4} to an aqueous solution of [(Me\textsuperscript{+}Py\textsubscript{8}CA\textsubscript{P}(OH)\textsubscript{2}] (pH range 7.5–9.2) results in instantaneous color changes. Spectrophotometric titration experiment reveals two consecutive reduction steps (Figure 2).

In the first stage characterized by color change from green to yellow the absorption band of the initial corrolazine complex [(Me\textsuperscript{+}Py\textsubscript{8}CA\textsubscript{P}(OH)\textsubscript{2}] at 660 nm disappears and new broadened and less intense Q band appears at 749 nm (Figure 2, spectra 1 and 2). Such spectral changes are typical for the formation of monoreduced complexes of porphyrine-type macrocycles.\cite{22,23} This process is fully completed at the [(Me\textsuperscript{+}Py\textsubscript{8}CA\textsubscript{P}(OH)\textsubscript{2}]//S\textsubscript{2}O\textsubscript{4}\textsuperscript{2–}] ratio = 2:1. Following addition of dithionite up to [(Me\textsuperscript{+}Py\textsubscript{8}CA\textsubscript{P}(OH)\textsubscript{2}]//S\textsubscript{2}O\textsubscript{4}\textsuperscript{2–}] ratio = 1:1 leads to brown color of the solution and all distinct absorption bands in the visible and near IR region disappear. This is typical for the 2\textsuperscript{nd} reduction of the macrocyclic chromophore in porphyrine-type complexes.\cite{24,26} The reduction of phosphorus atom (P\textsuperscript{V}/P\textsuperscript{III}) in such conditions can be excluded. In the cases when reduction occurs on coordinating central atom the Q band should be retained. In the case of octaaryl substituted P\textsuperscript{V} corrolazines the reduction occurs only by Na/NH\textsubscript{3} and leads to irreversible dephosphorylation.\cite{9}

In contrast to the initial corrolazine complex [(Me\textsuperscript{+}Py\textsubscript{8}CA\textsubscript{P}(OH)\textsubscript{2}] the reduced “yellow” and “brown” forms are not fluorescent. Both of them are stable and their

Figure 1. Electronic absorption (A) and emission (B) spectra of [(Me\textsuperscript{+}Py\textsubscript{8}CA\textsubscript{P}(OH)\textsubscript{2}] in water at pH = 4.0 (1), 7.5 (2) and 12 (3).

Figure 2. Electronic absorption spectra of water solutions of [(Me\textsuperscript{+}Py\textsubscript{8}CA\textsubscript{P}(OH)\textsubscript{2}] (10 \textmu M) at pH = 9.2 (1) and its mono-electron (2) and two-electron (3) reduction products formed after addition of Na\textsubscript{2}S\textsubscript{2}O\textsubscript{4} (5 \textmu M (2) and 10 \textmu M (3)).
spectrum remain invariable in anaerobic conditions and room

temperature at pH 7.0–9.2 for at least 12 hours. When oxygen

is bubbled through solutions of “yellow” and “brown” forms

or they are exposed in the aerobic conditions their color turns again green and the electronic absorption and emission spectra of the initial complex [(Me \textsuperscript{+}Py)\textsubscript{8}C\textsubscript{4}P(OH\textsubscript{3})\textsubscript{2}] are completely recovered. This indicates that P\textsuperscript{v} corrolazine is reversibly reduced by Na\textsubscript{2}S\textsubscript{2}O\textsubscript{4}.

Sodium dithionite is a two-electron reducing agent, being oxidized to sulfate.\textsuperscript{[14]} Given the reversible character of the spectral changes, it could be assumed that upon dithionite action the consecutive formation of the products corresponding to one- and two-electron reduction of the π-chromophore is observed:

\[
2 2\text{[(Me+Py)\textsubscript{8}C\textsubscript{4}P(OH\textsubscript{3})\textsubscript{2} + S\textsubscript{2}O\textsubscript{4}^2\textsuperscript{−} + 2 H\textsubscript{2}O} \rightarrow 2\text{[(Me+Py)\textsubscript{8}C\textsubscript{4}P(OH\textsubscript{3})\textsubscript{2}^\textsuperscript{+} + 2 HS\textsubscript{2}O\textsubscript{3}^− + 2 H\textsuperscript{+}}.
\]

\[
2\text{[(Me+Py)\textsubscript{8}C\textsubscript{4}P(OH\textsubscript{3})\textsubscript{2}^\textsuperscript{2}− + S\textsubscript{2}O\textsubscript{4}^2\textsuperscript{−} + 2 H\textsubscript{2}O} \rightarrow 2\text{[(Me+Py)\textsubscript{8}C\textsubscript{4}P(OH\textsubscript{3})\textsubscript{2}^− + 2 HS\textsubscript{2}O\textsubscript{3}^− + 2 H\textsuperscript{+}}.
\]

We have also studied the interaction of water soluble P\textsuperscript{v} corrolazine with cyanocobalamin [(CN)Cbl(III)] and its reduced forms [(Cbl(II)] and [Cbl(I)] as natural reductants. When [(CN)Cbl(III)] or [Cbl(II)] was added to neutral aqueous solution of [(Me+Py)\textsubscript{8}C\textsubscript{4}P(OH\textsubscript{3})\textsubscript{2}] the resulting electronic absorption spectrum was a superposition of the spectra of the initial compounds and no spectral changes could be observed upon staying (Figure 3). However in the emission spectra some decrease of fluorescence intensity of P\textsuperscript{v} corrolazine complex is observed in the presence of [(CN)Cbl(III)]. The absence of changes in the electronic absorption spectrum with simultaneous quenching of fluorescence might be indicative about π-π interaction between π-systems of corrolazine and cobalamin macrocycles. Formation of cobalamin π-complexes with other tetrapyrrolic macrocycles, e.g. iron porphyrins, was also observed.\textsuperscript{[27]}

Addition of [(Me\textsuperscript{+}Py)\textsubscript{8}C\textsubscript{4}P(OH\textsubscript{3})\textsubscript{2}] to aqueous solution of super-reduced B\textsubscript{12} leads to remarkable changes in its electronic absorption spectrum (Figure 4) accompanied by disappearance of the initial bands at 370 and 685 nm characteristic for [Cbl(I)] and appearance of new bands at 312 and 474 nm typical for [Cbl(II)]. This fact indicates a redox reaction between the corrolazine and super-reduced cobalamin complexes. The complete reduction of [(Me\textsuperscript{+}Py)\textsubscript{8}C\textsubscript{4}P(OH\textsubscript{3})\textsubscript{2}] requires 2 moles of [Cbl(I)]. Since the peak at 750 nm characteristic for the first reduced form of P\textsuperscript{v} corrolazine is lost in the final spectrum, the doubly reduced product is most likely formed:

\[
\text{[(Me+Py)\textsubscript{8}C\textsubscript{4}P(OH\textsubscript{3})\textsubscript{2} + 2 [Cbl(I)]} \rightarrow \text{[(Me+Py)\textsubscript{8}C\textsubscript{4}P(OH\textsubscript{3})\textsubscript{2}^\textsuperscript{2}− + 2 [Cbl(II)]}
\]

[(Me\textsuperscript{+}Py)\textsubscript{8}C\textsubscript{4}P(OH\textsubscript{3})\textsubscript{2}] can be reduced by [Cbl(II)], but not by [Cbl(I)]. It is known that redox potentials [Cbl(II)/(III)] and [Cbl(I)/(II)] are 0.0 and –0.85 V vs. Ag/AgCl, respectively.\textsuperscript{[28]} This means that potentials of the first and second reduction of the macrocycle for [(Me\textsuperscript{+}Py)\textsubscript{8}C\textsubscript{4}P(OH\textsubscript{3})\textsubscript{2}] should be observed in the range from 0.0 to –0.85 V vs. Ag/AgCl. For octaaryl substituted P\textsuperscript{v} corrolazines [Ar\textsubscript{8}C\textsubscript{4}P(OEMe\textsubscript{4})] (Ar = 4-\textit{tert}-butylphenyl, 4-metoxyphenyl) the 1\textsuperscript{st} reduction of the macrocycle at –0.8 V was followed by P\textsuperscript{v}/P\textsuperscript{iii} couple at –1.33 V.\textsuperscript{[13,19]} Since 2-pyridyl groups have the stronger acceptor properties which are additionally enhanced by their quaternization it is not surprising that two first reductions of the macrocycle in [(Me\textsuperscript{+}Py)\textsubscript{8}C\textsubscript{4}P(OH\textsubscript{3})\textsubscript{2}] are observed at less negative potentials than P\textsuperscript{v}/P\textsuperscript{iii} couple. Indeed the 1\textsuperscript{st} and 2\textsuperscript{nd} reductions of the macrocycle in the case of metal-free 2-pyridyl substituted porphyrine [Py\textsubscript{8}P(AH\textsubscript{3})\textsubscript{2}] are observed at –0.26 and –0.65 V vs. SCE in pyridine,\textsuperscript{[29,30]} and quaternization of 2-pyridyl groups facilitates the 1\textsuperscript{st} and 2\textsuperscript{nd} reduction of porphyrine macrocycle by 0.15–0.25 V.\textsuperscript{[26]}

Interaction of reduced forms of P\textsuperscript{v} corrolazine with cobalamin was also studied. The double reduced form [(Me\textsuperscript{+}Py)\textsubscript{8}C\textsubscript{4}P(OH\textsubscript{3})\textsubscript{2}] does not react with cyanocobalamin [(CN)Cbl(III)] which has the reduction potential Co\textsuperscript{III}/Co\textsuperscript{II} at –1.00 V.\textsuperscript{[29]} However aquacobalamin [H\textsubscript{2}O]Cbl(III)] having

![Figure 3](image3.png)

**Figure 3.** Electronic absorption spectra of cyanocobalamin [(CN)Cbl(III)] (1) and its mixture with [(Me+Py)\textsubscript{8}C\textsubscript{4}P(OH\textsubscript{3})\textsubscript{2}] (2) in water at pH = 7.5. Insert shows the dependence of fluorescence intensity at 665 nm on the concentration of [Cbl(III)].

![Figure 4](image4.png)

**Figure 4.** The spectral changes during the interaction of [Cbl(I)] with [(Me\textsuperscript{+}Py)\textsubscript{8}C\textsubscript{4}P(OH\textsubscript{3})\textsubscript{2}] in aqueous solution in anaerobic conditions (pH = 7.5, 25°C). 1 – initial spectrum of [Cbl(I)] (30 μM), 2 – after addition of [(Me\textsuperscript{+}Py)\textsubscript{8}C\textsubscript{4}P(OH\textsubscript{3})\textsubscript{2}] (15 μM).
much more positive reduction potentials (CoII/Co0 at 0.0 V and CoIII/Co2 at –0.85 V[1]) can easily oxidize the reduced forms of P5 corrolazine. Thus, when excess of [(H2O)Cbl(III)] is added to aqueous solution of the double reduced form [(MePy)C4P(OH)2]2– one can observe its immediate reduction to a single reduced form [(MePy)C4P(OH)2]2– characterized by Q band at 758 nm (Figure 5, spectra 1 and 2). This process is followed by slower reduction step leading to disappearance of the band at 758 nm and appearance of the Q band at 677 nm typical for non-reduced P5 corrolazine existing in strongly basic medium (pH = 12.4) as deprotonated form of [(MePy)C4P(OH)2]2–. Each step requires 1 equivalent of [(H2O)Cbl(III)] as an oxidizer.

In conclusion, we have prepared new water soluble P5 corrolazine complex bearing N-methyl-2-pyridiniumyl groups and studied its behavior in basic aqueous solutions. In the presence of sodium dithionite corrolazine macrocycle is reversibly reduced in basic medium forming consequently single and double reduced π-anionic forms, while reduction of the coordinated P5 atom is not observed. P5 Corrolazine participates in π-interaction with cobalamins, e.g. with [(CN)Cbl(III)], while the super-reduced form of vitamin B12, [Cbl(I)], reduces it with formation of π-dianion, which in turn can be oxidized by aquacobalamin. It was also observed that central phosphonate moiety can be deprotonated in basic medium. The obtained results indicate that P5 corrolazine can be used as a mediator for catalytic processes involving cobalamins in basic medium, and the further results will be reported in due course.
