Abstract

We calculate the expectation values of the stress–energy bitensor defined at two different spacetime points $x$, $x'$ of a massless, minimally coupled scalar field with respect to a quantum state at finite temperature $T$ in a flat $N$-dimensional spacetime by means of the generalized zeta-function method. These correlators, also known as the noise kernels, give the fluctuations of energy and momentum density of a quantum field which are essential for the investigation of the physical effects of negative energy density in certain spacetimes or quantum states. They also act as the sources of the Einstein–Langevin equations in stochastic gravity which one can solve for the dynamics of metric fluctuations as in spacetime foams. In terms of constitutions these correlators are one rung above (in the sense of the correlation—BBGKY or Schwinger-Dyson—hierarchies) the mean (vacuum and thermal expectation) values of the stress–energy tensor which drive the semiclassical Einstein equation in semiclassical gravity. The low- and the high-temperature expansions of these correlators are also given here: at low temperatures, the leading order temperature dependence goes like $T^N$ while at high temperatures they have a $T^2$ dependence with the subleading terms exponentially suppressed by $e^{-T}$. We also discuss the singular behavior of the correlators in the $x' \to x$ coincident limit as was done before for massless conformal quantum fields.

This article is part of a special issue of *Journal of Physics A: Mathematical and Theoretical* in honour of Stuart Dowker’s 75th birthday devoted to ‘Applications of zeta functions and other spectral functions in mathematics and physics’.

1. Introduction

In this paper, we present a calculation of the stress tensor correlators, also known as the noise kernels, of a massless, minimally coupled scalar field at a finite temperature \( T \) in a flat \( N \)-dimensional spacetime by means of the generalized zeta-function method. The stress tensor correlator is the expectation value of the stress–energy bitensor defined at two separate spacetime points. The zeta-function method was first introduced by Dowker and Critchley \[1\] and Hawking \[2\] (see also \[3\]) and successfully applied to the regularization of ultraviolet divergences in stress tensors of quantum fields in curved spacetimes with Euclidean sections, e.g., static black holes and (anti-)de Sitter (AdS) space. It was generalized by Phillips and Hu \[4\] (see also \[5\]) for the calculation of stress–energy correlators. In an earlier paper \[6\], we mentioned three classes of physical problems of current interest which necessitate the knowledge of such quantities and motivated us to undertake this task for AdS spaces. Here, we also mention three classes of problems as motivation for our present endeavor of calculating the stress–energy correlators for finite-temperature quantum fields in curved spacetimes. Common to both endeavors foremost is the following.

(A) **The semiclassical stochastic gravity program** \[7\]. A theoretical framework that was established in the 1990s as a natural extension of the semiclassical gravity (SCG) theory of the 1980s \[8\], for including the effects of fluctuations in the quantum matter field through the Einstein–Langevin equation (ELEq), which governs the behavior of the induced metric fluctuations \[9\]. While SCG goes beyond the quantum field theory in curved spacetime (QFTCST) of the 1970s \[10\] (viewed as the test-field approximation of SCG on a fixed background spacetime), in which the backreaction of the quantum matter field on the dynamics of the spacetime is incorporated through the expectation value of the stress–energy tensor as the source of the semiclassical Einstein (SCEq) equation, stochastic gravity goes beyond SCG in which it includes also the backreaction of the fluctuations of the stress–energy tensor, measured by the expectation values of the stress–energy bitensor, also known as the noise kernel, which govern the behavior of the induced metric fluctuations.

(B) **Black hole fluctuations and backreaction.** Owing to the existence of an Euclidean section in static (e.g., Schwarzschild) black hole spacetimes, quantum field effects can be obtained via thermal field methods. For example, the Hawking effect can be derived with the use of the Euclidean Green function \[11\] whose periodicity corresponds to the inverse Hawking temperature. Fluctuations and backreaction of the stress–energy tensor near the black hole event horizon is an important issue \[12\], the investigation of this problem for Schwarzschild black holes requires knowledge of the thermal stress tensor correlator, which is the expectation value of the stress–energy bitensor with respect to the Hartle–Hawking state. Thermal stress tensor correlator calculation in hot flat space is the logical first step toward this goal, as was the motivation in the earlier work of Phillips and Hu \[13\]. In that paper, the authors use the Gaussian approximation \[14\] for the Green function for such quantum fields to evaluate the noise kernel in two optical metrics: hot flat space and the optical-Schwarzschild spacetime. The optical metric for an ultrastatic spacetime has the product form \( ds^2 = g_{ab} dx^a dx^b = dr^2 + g_{ij} dx^i dx^j \). In the Euclidean sector, we can allow the imaginary \( \tau \) time to possess a periodicity of \( 2\pi / \kappa = \beta = 1/T \), with \( T \) being the temperature, to connect with thermal field theories. (For a black hole, \( \kappa \) is the surface gravity.) For massless conformally coupled quantum fields in hot flat space, the Gaussian Green function is exact. For optical Schwarzschild, the Gaussian Green function is known to be a fairly good approximation for calculating the stress tensor which involves second covariant derivatives of the Green function. The noise kernels involve up to four covariant
derivatives of the Green function [15]. The Schwarzschild metric is obtained from the optical Schwarzschild by a conformal transformation.

This earlier work is followed by a recent paper [16] wherein the authors, instead of seeking the coincident limits of the noise kernel, calculated the point-separated expression (in both time-like and space-like directions) necessary to solve the equations of stochastic SCG, by the same Gaussian approximation for the Wightman function for conformally invariant fields. These authors have computed all components of the noise kernel exactly for hot flat space and several components for the Schwarzschild spacetime. They showed that the noise kernel for the conformally invariant field has a simple scaling behavior under conformal transformations which enables them to obtain the results for Schwarzschild spacetime from that for the optical-Schwarzschild metric.

(C) Negative energy density and fluctuations. Apart from applications to early universe and black hole physics, closer to home, the stress–energy correlators are directly relevant to the fluctuations of vacuum energy density, especially the existence of negative energy density as in flat space with boundaries (such as the Casimir energy) and for non-classical states (such as two-mode squeezed states). This issue was raised by Kuo and Ford [17], furthered by Wu and Ford [18] and pursued by Phillips and Hu [4, 19], where the fluctuations in energy density are shown to be comparable to its mean value for several classes of spacetimes (e.g., Einstein universe) and states (e.g., Casimir). Many related problems such as the quantum interest principle [20] bear on foundational issues of quantum field theory and spacetime structure. With generalization to finite temperature one can ask how this quantum vacuum behavior is altered by thermal fluctuations. Results for hot flat space were obtained in [13] for conformally invariant quantum fields. Our present results for massless minimally coupled fields in arbitrary dimensions complement and further these earlier studies.

The organization of this paper is as follows. In section 2, we introduce the generalized zeta-function method. In section 3, we use this method to calculate the stress–energy tensor correlator for a finite-temperature quantum field in flat $N$-dimensional space. In section 4, we give the expressions for high- and low-temperature expansions showing which components in the bitensor are dominant and how temperature and dimensionality alter this behavior. We also discuss the singular behavior of the correlators in the $x' \to x$ coincident limit. We conclude with some remarks in section 5. The detailed expressions are collected in appendices A, B and C. Our conventions are the same as in our earlier papers [6].

2. Generalized zeta-function method

In this section, we first introduce the generalized zeta-function method of Phillips and Hu [4] (see also [5]) based on the original methods of Dowker and Critchley [1] and Hawking [2]. This method has recently been used to consider the case of the stress–energy correlations in AdS spaces [6]. Here, we apply it to calculate such correlations in hot flat spaces.

To be general, we start by considering a massive $m$ scalar field $\phi$ coupled to an $N$-dimensional Euclideanized space (with the contravariant metric $g^{\mu\nu}(x)$, determinant $g$ and scalar curvature $R$) with the coupling constant $\xi$ described by the action

$$S[\phi] = \frac{1}{2} \int d^N x \sqrt{g(x)} \phi(x) H \phi(x), \quad (1)$$

where $H$ is the quadratic operator

$$H = -\Box + m^2 + \xi R. \quad (2)$$
and $R$ is the scalar curvature. The effective action defined by $W = \ln Z$ is related to the generating functional $Z$ by
\[ Z = \int D\phi \ e^{-S[\phi]}. \]  
(3)

The expectation value of the stress–energy tensor can be obtained by taking the functional derivative of the effective action
\[ \langle T_{\mu\nu} \rangle = -\frac{2}{\sqrt{g(x)}} \frac{\delta W}{\delta g^{\mu\nu}(x)}. \]  
(4)

This formal expression is divergent at the coincident limit and some procedure of regularization needs to be implemented. Here, we adopt the $\zeta$-function regularization scheme of [1, 2].

The $\zeta$-function of an operator $H$ is defined as
\[ \zeta_H(s) = \sum_n \left( \frac{\mu}{\lambda_n} \right)^s = \text{Tr} \left( \frac{\mu}{H} \right)^s, \]  
(5)

where $\lambda_n$ are the eigenvalues of $H$ and $\mu$ represents the renormalization scale. The $\zeta$-function regularized effective action of the operator $H$ is
\[ W_R = \frac{1}{2} \frac{d\zeta}{ds} \bigg|_{s \to 0}. \]  
(6)

Using the proper-time method of Dowker and Critchley [1], one can write the $\zeta$-function as
\[ \zeta_H(s) = \frac{\mu^s}{\Gamma(s)} \int_0^\infty dt \ t^{-1} \text{Tr} \ e^{-tH}, \]  
(7)

\[ W_R = \frac{1}{2} \frac{d}{ds} \left[ \frac{\mu^s}{\Gamma(s)} \int_0^\infty dt \ t^{-1} \text{Tr} \ e^{-tH} \right] \bigg|_{s \to 0}. \]  
(8)

Taking the first variation of the $\zeta$-function,
\[ \delta \zeta_H = -\frac{\mu^s}{\Gamma(s)} \int_0^\infty dt \ t \text{Tr} (\delta H e^{-tH}), \]  
(9)

we obtain the regularized expectation value of the stress–energy tensor given by
\[ \langle T_{\mu\nu}(x) \rangle = \frac{1}{2} \frac{d}{ds} \left[ -\frac{\mu^s}{\Gamma(s)} \int_0^\infty dt \ t \sum_n e^{-\lambda_n t} \left( -\frac{2}{\sqrt{g(x)}} (n| \delta H |n) \right) \right] \bigg|_{s \to 0}, \]  
(10)

where
\[ T_{\mu\nu}[\phi_n(x), \phi^*_n(x)] = -\frac{2}{\sqrt{g(x)}} (n| \delta H |n) \]  
(11)

Here, $\phi_n(x)$ are the normalized eigenfunctions of the operator $H$ corresponding to the eigenvalues $\lambda_n$:
\[ H\phi_n = \lambda_n\phi_n. \]  
(12)
With the form of $H$ given by (2), we have

$$T_{\mu\nu} \left[ \phi_n(x), \phi_n^*(x) \right] = \left( -\partial_\mu \phi_n \partial_\nu \phi_n + \partial_\mu \phi_n^* \partial_\nu \phi_n + g_{\mu\nu} (g^{\rho\alpha} \partial_\rho \phi_n \partial_\alpha \phi_n + \phi_n^* \Box \phi_n) \right. $$

$$ \left. - 2 \xi [g_{\mu\nu} \Box (\phi_n^* \phi_n) - \nabla_\mu \nabla_\nu (\phi_n^* \phi_n) + R_{\mu\nu} \phi_n^* \phi_n] \right).$$  

(13)

Using the Schwinger method [21], Phillips and Hu [4] generalized the $\zeta$-function method for the consideration of the stress–energy correlators. The second variation of the $\zeta$-function can be written as

$$\delta_2 \delta_i \zeta_H = \frac{\mu^2}{2 \Gamma(s)} \int_0^\infty du \int_0^\infty dv (u + v)^s (uv) \times \left[ \text{Tr}[(\delta_1 H) e^{-\alpha_1 H} (\delta_2 H) e^{-\alpha_2 H}] + \text{Tr}[(\delta_2 H) e^{-\alpha_1 H} (\delta_1 H) e^{-\alpha_2 H}] \right]$$

(14)

and

$$\Delta T_{\mu\nu;\rho\sigma}^2 (x, x') \equiv \left< T_{\mu\nu}(x) T_{\rho\sigma}^* (x') \right> - \left< T_{\mu\nu}(x) \right> \left< T_{\rho\sigma}^* (x') \right>$$

$$= \frac{4}{\sqrt{g(x)g(x')}} \frac{\mu^2}{2 \Gamma(s)} \int_0^\infty du \int_0^\infty dv (u + v)^s (uv) \sum_{n, n'} e^{-u \omega_n - v \omega_{n'}}$$

$$\times T_{\mu\nu} \left[ \phi_n(x), \phi_n^* (x) \right] T_{\rho\sigma}^* \left[ \phi_{n'} (x'), \phi_{n'}^* (x') \right] \bigg|_{s, v \to 0}.$$

(15)

Note that in this prescription an additional regularization factor $(uv)^s$ has been introduced. This is because the authors of [4] were interested in the fluctuations of the stress–energy tensor, that is, in the coincident limit of $\Delta T_{\mu\nu;\rho\sigma}^2 (x, x')$ where under this limit further divergences occur which call for an additional regularization factor. (See also [5].) However, our present purpose is focused on getting the correlators with two points separated, i.e. in the non-coincident case. Hence, apart from the fact that the expression in equation (15) is more symmetric with this factor, the keeping of this factor above is actually a matter of convenience. Here, we can first take the $s \to 0$ limit without spoiling the regularization and the expression in equation (15) becomes

$$\Delta T_{\mu\nu;\rho\sigma}^2 (x, x') = \frac{1}{2} \int_0^\infty du \int_0^\infty dv (uv) \sum_{n, n'} e^{-u \omega_n - v \omega_{n'}}$$

$$\times T_{\mu\nu} \left[ \phi_n(x), \phi_n^* (x) \right] T_{\rho\sigma}^* \left[ \phi_{n'} (x'), \phi_{n'}^* (x') \right] \bigg|_{s, v \to 0}.$$

(16)

We shall see from the following calculations that with this expression the integrations over $u$ and $v$ effectively separate. The calculations are therefore simplified considerably.

3. Stress–energy correlators in hot flat spaces

We now apply this generalized $\zeta$-function method to calculate the stress–energy correlators of massless, minimally coupled quantum fields in hot flat spaces. The $N$-dimensional Euclidean flat space metric has the form

$$ds^2 = dr^2 + d\vec{r} \cdot d\vec{r},$$

(17)

where $r$ has the periodicity $\beta = 1/T$. The operator $H$ is just $-\Box$ and the corresponding normalized eigenfunctions are

$$\phi_n(r, \vec{x}) = \frac{1}{(2\pi)^{(N-1)/2} \sqrt{\beta}} e^{i n_\mu r + i \vec{n} \cdot \vec{x}},$$

(18)
discuss the corresponding singular behavior of the correlators in the temperature is quite different in the low- and the high-temperature regimes. We shall also

\[ J. \text{Phys.} \ A: \text{Math. Theor.} \ 45 \ (2012) \ 374013 \ H \ T \ Cho \ and \ B \ L \ Hu \]

where \( \omega_n = 2\pi n/\beta \) for \( n = 0, \pm 1, \pm 2, \ldots, \) and

\[ \int_0^\beta d\tau \int d^{d-1}\! x \delta_{\mu\nu} \phi^*_m(\tau, \vec{x}) \phi_n(\tau, \vec{x}) = \delta_{mn} \delta(\vec{k} - \vec{k}). \]  

(19)

From the tensorial structure of the \( \Delta T^2_{\mu\nu|\beta}(x, x') \), one can define the scalar coefficient functions as follows [22, 23, 6]:

\[ \Delta T^2_{0000}(x, x') = C_{11} \]

(20)

\[ \Delta T^2_{00ij}(x, x') = C_{21} \delta_{ij} \]

(21)

\[ \Delta T^2_{0ij}(x, x') = C_{31} \delta_{ij} + C_{32} (\vec{x} - \vec{x}')_i (\vec{x} - \vec{x}')_j \]

(22)

\[ \Delta T^2_{0ij}(x, x') = C_{41} \delta_{ij} + C_{42} (\vec{x} - \vec{x}')_i (\vec{x} - \vec{x}')_j \]

(23)

\[ \Delta T^2_{0ij}(x, x') = C_{51} (\vec{x} - \vec{x}')_i \delta_{jk} + C_{52} (\vec{x} - \vec{x}')_k + \delta_{ik}(\vec{x} - \vec{x}')_j \]

\[ + C_{53} (\vec{x} - \vec{x}')_i (\vec{x} - \vec{x}')_j (\vec{x} - \vec{x}')_k \]

(24)

\[ \Delta T^2_{ijk}(x, x') = C_{61} \delta_{ij} \delta_{kl} + C_{62} (\delta_{ik} \delta_{jl} + \delta_{il} \delta_{jk}) \]

\[ + C_{63} \delta_{ik}(\vec{x} - \vec{x}')_l (\vec{x} - \vec{x}')_j + \delta_{lj}(\vec{x} - \vec{x}')_i (\vec{x} - \vec{x}')_k \]

\[ + C_{64} \delta_{il}(\vec{x} - \vec{x}')_j (\vec{x} - \vec{x}')_k + \delta_{ji}(\vec{x} - \vec{x}')_l (\vec{x} - \vec{x}')_k \]

\[ + C_{65} (\vec{x} - \vec{x}')_i (\vec{x} - \vec{x}')_j (\vec{x} - \vec{x}')_k \]

(25)

where, owing to the homogeneity of the space, the coefficients \( C_{\alpha\beta} \) are functions of \( \tau - \tau' \) and \( |\vec{x} - \vec{x}'| \) only.

The components of \( T^\alpha_{\mu\nu}[\phi^*_m(\tau, \vec{x}), \phi^*_n(\tau', \vec{x}')] \) in hot flat space are

\[ T_0[\phi^*_m(\tau, \vec{x}), \phi^*_n(\tau', \vec{x}')] = [-\omega_n (\omega_n + \omega_{\nu'}) - \vec{k} \cdot (\vec{k} - \vec{k})] \phi^*_m(\tau, \vec{x}), \phi^*_n(\tau', \vec{x}') \]

(26)

\[ T_0[\phi^*_m(\tau, \vec{x}), \phi^*_n(\tau', \vec{x}')] = [-\omega_n k'_i - \omega_n k_j] \phi^*_m(\tau, \vec{x}), \phi^*_n(\tau', \vec{x}') \]

(27)

\[ T_0[\phi^*_m(\tau, \vec{x}), \phi^*_n(\tau', \vec{x}')] = [-k_i k'_j - k_j k'_i - \omega_n (\omega_n - \omega_{\nu'}) + \vec{k} \cdot (\vec{k} - \vec{k})] \]

\[ \times \phi^*_m(\tau, \vec{x}), \phi^*_n(\tau', \vec{x}') \]

(28)

The coefficients \( C_{\alpha\beta} \) can be expressed in terms of the function \( f(\alpha) \),

\[ f(\alpha) = \sum_{n=-\infty}^{\infty} \int_0^\infty du u^{-\alpha} e^{-\omega u} e^{-|\vec{x} - \vec{x}'|^2/4u} e^{i\omega_n (\tau - \tau')}, \]

(29)

and its \( \tau \) derivatives. These expressions can be found in appendix A.

4. Low- and high-temperature expansions of the correlators

To develop the low- and high-temperature expansions of the correlators, we look at the corresponding behavior of the function \( f(\alpha) \) defined in equation (29). In fact, for the low-temperature regime, a Poisson summation formula has to be used to obtain the appropriate form of \( f(\alpha) \). In these expansions, we shall see that the dependence of the correlators on the temperature is quite different in the low- and the high-temperature regimes. We shall also discuss the corresponding singular behavior of the correlators in the \( x \to x' \) coincident limit.
4.1. High-temperature expansion

First, for high temperature or small $\beta$, $\omega_n = 2\pi n/\beta$ is always large except for $n = 0$. Hence, we need to treat the $n = 0$ term separately as follows:

$$f(\alpha) = \int_0^\infty du u^{-\alpha} e^{-|\vec{x} - \vec{x}'|/4u} + 2 \sum_{n=1}^\infty \cos[\omega_n(\tau - \tau')] \int_0^\infty du u^{-\alpha} e^{\omega_n^2 |\vec{x} - \vec{x}'|^2/4u}$$

$$= 4^{\alpha-1} \Gamma(\alpha - 1) [(\vec{x} - \vec{x}')]^2 \alpha^{-\alpha} + 2 \sum_{n=1}^\infty 2^{\alpha+1} [(\vec{x} - \vec{x}')]^2 \alpha^{-\alpha}$$

$$\times \left( \frac{2\pi n|\vec{x} - \vec{x}'|}{\beta} \right)^{\alpha-1} \cos \left( \frac{2\pi n(\tau - \tau')}{\beta} \right) K_{\alpha-1} \left( \frac{2\pi n|\vec{x} - \vec{x}'|}{\beta} \right).$$

(30)

Using the asymptotic expansion of the modified Bessel function $K_\nu(z)$ for large $z$, we can further expand $f(\alpha)$ as follows:

$$f(\alpha) = 4^{\alpha-1} \Gamma(\alpha - 1) [(\vec{x} - \vec{x}')]^2 \alpha^{-\alpha} \left( 1 + \frac{2\pi^{\alpha-1}}{\Gamma(\alpha - 1)} e^{-2\pi|\vec{x} - \vec{x}'|/\beta} \left( \frac{|\vec{x} - \vec{x}'|}{\beta} \right)^{\alpha-1} \right.$$  

$$\times \cos \left( \frac{2\pi (\tau - \tau')}{\beta} \right) \left[ 1 + \left( \frac{\alpha - \frac{1}{2}}{4\pi} \right) \left( \frac{\beta}{|\vec{x} - \vec{x}'|} \right) + \cdots \right].$$  

(31)

This asymptotic series of $f(\alpha)$ can now be used to develop the high-temperature expansions of the correlator components. They are listed in appendix B. From equations (B.1) to (B.6), we see that the density–density correlator $\Delta T_{0000}(x, x')$, the density–pressure correlators $\Delta T_{00ij}(x, x')$ and the pressure–pressure correlators $\Delta T_{ijij}(x, x')$ are of the order of $1/\beta^2$ or $T^2$, while $\Delta T_{00ij}(x, x')$, $\Delta T_{00ij}(x, x')$ and $\Delta T_{ijij}(x, x')$ are suppressed by $e^{-T}$.

Next, we investigate the singular behavior of the correlators in the $x' \to x$ coincident limit. Note that for the high-temperature expansion to work, we must have $|\vec{x} - \vec{x}'|$ and $|\tau - \tau'|$ both larger than $\beta$. Hence, here we take $x \to x'$ with $\beta$ also approaching zero while keeping both $|\vec{x} - \vec{x}'|$ and $|\tau - \tau'| > \beta$. Now since the space is homogeneous and isotropic, we can average over the directions in this limit. This amounts to replacing $(\vec{x} - \vec{x}')_i (\vec{x} - \vec{x}')_j / (N - 1)$ and $(\vec{x} - \vec{x}')_i (\vec{x} - \vec{x}')_j (\vec{x} - \vec{x}')_l$ with $\delta_{ij} \delta_{kl}$.

The correlators are

$$\Delta T_{0000}(x, x') \sim \frac{(N - 1)(N - 2) \Gamma^2 [(N - 1)/2]}{8\pi^{N-1} |\vec{x} - \vec{x}'|^{2N-2} \beta^2}$$

(32)

$$\Delta T_{00ij}(x, x') \sim \frac{(N - 2)(N - 3) \Gamma^2 [(N - 1)/2]}{8\pi^{N-1} |\vec{x} - \vec{x}'|^{2N-2} \beta^2} \delta_{ij}$$

(33)

$$\Delta T_{ijkl}(x, x') \sim \frac{(N^4 - 6N^2 + 7N + 6) \Gamma^2 [(N - 1)/2]}{8(N + 1)\pi^{N-1} |\vec{x} - \vec{x}'|^{2N-2} \beta^2}$$

$$\times \left[ \delta_{ij} \delta_{kl} + \frac{2(N - 3)}{N^3 - 6N^2 + 7N + 6} \left( \delta_{ik} \delta_{jl} + \delta_{il} \delta_{jk} \right) \right].$$

(34)

For example, for $N = 4$, we have

$$\Delta T_{0000}(x, x') \sim \frac{3}{16\pi^2} \frac{1}{|\vec{x} - \vec{x}'|^{6} \beta^2}$$

(35)

$$\Delta T_{00ij}(x, x') \sim \frac{1}{16\pi^2} \frac{1}{|\vec{x} - \vec{x}'|^{6} \beta^2} \delta_{ij}$$

(36)
\[\Delta T_{ijkl}^2(x, x') \sim \frac{1}{80\pi^2} \left( \frac{1}{|\vec{x} - \vec{x}'|^6 \beta^2} \right) (\delta_{ij}\delta_{kl} + \delta_{ik}\delta_{jl} + \delta_{il}\delta_{jk}). \] (37)

The density–density fluctuation is larger than the other fluctuations. However, when \(N\) is large, all these three fluctuations have the same \(N^2 \Gamma^2 [(N-1)/2]\) dependence.

### 4.2. Low-temperature expansion

To find the low-temperature expansion for the correlators we again consider the function \(f(\alpha)\). The definition in equation (29) is not suitable for this purpose. An appropriate form can be obtained using the Poisson summation formula (see, for example, [24]):

\[\sum_{n=-\infty}^{\infty} g(n\beta) = \frac{\sqrt{2\pi}}{\beta} \tilde{g} \left( \frac{2\pi n}{\beta} \right), \] (38)

where \(\tilde{g}(k)\) is the Fourier transform of \(g(x)\):

\[\tilde{g}(k) = \int_{-\infty}^{\infty} \frac{dx}{\sqrt{2\pi}} e^{-ikx} g(x).\] (39)

Taking \(g(x) = e^{-4\pi^2|x|^2/\beta^2 + 2\pi (x-x')/\beta^2}\), we have

\[\sum_{n=-\infty}^{\infty} e^{in\beta} e^{in\beta} = \sum_{n=-\infty}^{\infty} \frac{\beta}{\sqrt{3\pi u}} e^{-\beta^2 n^2/4u}\] (40)

and the function \(f(\alpha)\) becomes

\[f(\alpha) = \sum_{n=-\infty}^{\infty} \frac{2^{2\alpha-1} \Gamma(\alpha + 1/2) \beta}{\sqrt{4\pi}} [(\vec{x} - \vec{x'})^2 + (\tau - \tau')^2 \alpha]^{-\alpha + 1/2}. \] (41)

In this form, one can expand in powers of \(1/\beta\) for large \(\beta\) or low temperature:

\[f(\alpha) = \frac{2^{2\alpha-1} \Gamma(\alpha + 1/2) \beta}{\sqrt{4\pi}} [(\vec{x} - \vec{x'})^2 + (\tau - \tau')^2 \alpha]^{-\alpha + 1/2} + \frac{2^{2\alpha-1} \Gamma(\alpha + 1/2) \beta}{\sqrt{4\pi}} (\alpha - 1) \frac{2\alpha - 1}{\sqrt{\beta^2 \alpha^2 - 2}} \left\{ \right. \]

\[\left. \frac{1 - (2\alpha - 1)\xi (2\alpha + 1)}{2\xi (2\alpha - 1)} \right\}. \] (42)

Using this expansion we can develop the low-temperature expansions of the correlators. They are listed in appendix C. We make two observations. (1) From equations (C.3) to (C.8), we see that when \(\beta \to \infty\) or \(T \to 0\), the correlators reduce to the ones in a \(R^N\) space. One can check that the values we obtain here are the same as the ones in [6]. (2) The leading temperature dependences of the correlators are all \(1/\beta^N\) or \(T^N\).

To investigate the singular behavior of the correlators in the coincident limit in this low-temperature regime, we first take the \(\tau' \to \tau\) limit. In this limit \(\Delta T_{000}^2\) and \(\Delta T_{0ij}^2\) vanish. Then we average over the directions in the other correlators giving

\[\Delta T_{000}^2(x, x') \sim \frac{N(N-1) \Gamma^2 (N/2)}{8\pi^N |\vec{x} - \vec{x}'|^{2N}} \left[ 1 - \frac{4\xi (N)}{N-1} \left( \frac{\vec{x} - \vec{x}'}{\beta} \right)^N \right] \] (43)

\[\Delta T_{0ij}^2(x, x') \sim \frac{(N^3 - 4N^2 + N + 4) \Gamma^2 (N/2) \delta_{ij}}{8(N-1)\pi^N |\vec{x} - \vec{x}'|^{2N}} \left[ 1 + \frac{4(N^2 - 3N + 4)\xi (N)}{(N^3 - 4N^2 + N + 4)} \left( \frac{\vec{x} - \vec{x}'}{\beta} \right)^N \right] \] (44)

\[\Delta T_{0ij}^2(x, x') \sim -\frac{\Gamma^2 (N/2) \delta_{ij}}{4(N-1)\pi^N |\vec{x} - \vec{x}'|^{2N}} \left[ 1 - 4(N-1)\xi (N) \left( \frac{\vec{x} - \vec{x}'}{\beta} \right)^N \right] \] (45)
\[ \Delta T_{ijkl}(x, x') \sim \frac{(N^4 - 5N^3 + 3N^2 + 9N + 4)\Gamma^2(N/2)(\delta_{ij}\delta_{kl})}{8(N^2 - 1)\pi^N|x - x'|^{2N}} \times \left[ 1 - \frac{4(N - 1)(N^2 + 7N - 4)\zeta(N)}{(N^4 - 5N^3 + 3N^2 + 9N + 4)\beta^N} \right] \Delta T_{0000}(x, x') \sim \frac{3}{2\pi^4|x - x'|^8} \left[ 1 - \frac{2\pi^4}{135} \left( \frac{|x - x'|}{\beta} \right)^4 \right] (46) \]

From the signs of the temperature-dependent terms, we see that the finite-temperature effect tends to increase the density–pressure fluctuation, while it decreases all the other fluctuations.

To see their relative magnitudes we examine the four-dimensional case. Setting \( N = 4 \) in the above we obtain

\[ \Delta T_{0000}(x, x') \sim \frac{3}{2\pi^4|x - x'|^8} \left[ 1 - \frac{2\pi^4}{135} \left( \frac{|x - x'|}{\beta} \right)^4 \right] \quad (47) \]

\[ \Delta T_{00ij}(x, x') \sim \frac{\delta_{ij}}{3\pi^4|x - x'|^8} \left[ 1 + \frac{2\pi^4}{45} \left( \frac{|x - x'|}{\beta} \right)^4 \right] \quad (48) \]

\[ \Delta T_{0ij0}(x, x') \sim \frac{-\delta_{ij}}{12\pi^4|x - x'|^8} \left[ 1 - \frac{2\pi^4}{15} \left( \frac{|x - x'|}{\beta} \right)^4 \right] \quad (49) \]

\[ \Delta T_{ijkl}(x, x') \sim \frac{\delta_{ij}\delta_{kl}}{5\pi^4|x - x'|^8} \left[ 1 - \frac{2\pi^4}{9} \left( \frac{|x - x'|}{\beta} \right)^4 \right] + \frac{7(\delta_k\delta_{ij} + \delta_i\delta_{jk})}{60\pi^4|x - x'|^8} \left[ 1 - \frac{2\pi^4}{105} \left( \frac{|x - x'|}{\beta} \right)^4 \right]. \quad (50) \]

Here, the finite-temperature effect is larger for the pressure–pressure fluctuation than the others. On the other hand, for large values \( N \), the current–current fluctuation goes like \( 4N\zeta(N) \), while the other fluctuations all go like \( 4\zeta(N)/N \).

5. Concluding remarks

In this paper, we have calculated the stress–energy tensor correlators of a massless, minimally coupled scalar quantum field in hot \( N \)-dimensional flat spaces. With the help of the Poisson summation formula we are able to develop low temperature as well as high-temperature expansions of these correlators. Low- and high-temperature regimes are determined by whether \( T \) is smaller or larger than \( |x - x'| \) and \( |\tau - \tau'| \), the only dimensional parameter in the problem. The results are collected in the appendices. The expressions there are a bit lengthy. First, a simple check can be done by comparing with the results in [6] where the correlators of a generally coupled scalar in \( N \)-dimensional flat spaces are given. The temperature-independent terms in appendix C agree with that in [6], when the coupling there is set to zero. Moreover, the correlators should be conserved. This is indeed the case as one can check, for example, that \( \partial^0\Delta T_{0000} + \partial^0\Delta T_{00i0} \) vanishes for both the low- and high-temperature expansions. In two dimensions, the massless minimally coupled scalar considered here is conformal so the correlators should be traceless. This can be shown in the expansions such that, for example,
\[ \Delta T_{0000}^2 + \Delta T_{00}^2 \] vanishes when \( N \) is set to 2. The expressions in the low- and high-temperature regimes are also related to the phenomenon of dimensional reduction. The leading behavior of the spatial components of the correlators in the high-temperature limit is equal to \( \beta^{-2} \times \) times the zero temperature correlators with one less dimension.

From the low- and high-temperature expansions, we see that the correlators have rather different behavior in these regimes. For low temperature, all the correlators have finite-temperature corrections of the order \( T \). However, for high temperature, density–density, density–pressure and pressure–pressure correlators are of the order \( T^2 \), while the other correlators are suppressed by \( e^{-T} \). We have also investigated the quantum fluctuations of the stress–energy tensor by considering the singular behavior of the correlators under the \( x' \to x \) coincident limit. Here, we first take \( \tau' \to \tau \) and then average over the directions. In the low-temperature regime, we see that the finite-temperature contributions tend to decrease the magnitude of fluctuations because the vacuum and the thermal fluctuations are of opposite signs, except for \( \Delta T_{00}^2 \). On the other hand, in the high-temperature regime, all the unsuppressed correlators have similar magnitude, which go like \( N^2 \Gamma^2 [(N - 1)/2] \) for large \( N \). Note that in this limit, both \( \beta = 1/T \) and \( |\vec{x} - \vec{x}'| \) are small but \( |\vec{x} - \vec{x}'| > \beta \) is always assumed in our approximation.

It would be interesting to see how this behavior would change with the introduction of another dimensional parameter. For example, we can consider massive scalars or background spacetime with non-zero curvature, like in [6]. We do not expect the high-temperature behavior to change. However, the low-temperature behavior might be altered. This makes careful consideration of finite yet small temperature corrections to the established results involving quantum vacuum quantities, such as negative energy density, and theorems derived therefrom, such as the quantum interest principle, worthwhile. We hope to address these foundational issues of importance and report our findings certainly on, if not before, the occasion of Professor Dowker’s 80th birthday celebration.

Here’s wishing you, Stuart, many happy returns!

Appendix A. Coefficient functions

The coefficient functions of the stress–energy correlators in equations (20)–(25) with \( \nu = (N - 1)/2 \) are as follows:

\[
C_{11}(\tau - \tau', |\vec{x} - \vec{x}'|) = \frac{1}{2(4\pi)^{N-1} \beta^2} \left[ 2 \partial_x^2 f(\nu) \partial_x^2 f(\nu) - 2 \partial_x^2 f(\nu) \partial_x f(\nu) \right] + (N - 1) \left[ \partial_x f(\nu) \partial_x f(\nu + 1) - f(\nu + 1) \partial_x^2 f(\nu) \right] + \frac{N(N - 1)}{4} f(\nu + 1) f(\nu + 1) - \frac{(\vec{x} - \vec{x}')^2}{2} \left[ \partial_x f(\nu) \partial_x f(\nu + 2) - f(\nu + 2) \partial_x^2 f(\nu) \right]
\]
\[
\partial_{\tau'} f(v + 1) \partial_{\tau} f(v + 1) - f(v + 1) \partial_{\tau}^2 f(v + 1) + \frac{2N + 1}{2} f(v + 1) f(v + 2)
\]
\[
+ \frac{(\vec{x} - \vec{x}')^4}{8} [f(v + 2) f(v + 2) + f(v + 1) f(v + 3)]
\]
(A.1)

\[
C_{21}(\tau - \tau', |\vec{x} - \vec{x}'|) = \frac{1}{2(4\pi)^{N-1} \beta^2} \left\{ \frac{1}{2} \partial_{\tau}^2 f(v + 1) \partial_{\tau} f(v) - \frac{1}{2} \partial_{\tau} f(v + 1) \partial_{\tau}^2 f(v)
\right.
\]
\[
+ \frac{N + 1}{4} [f(v + 1) \partial_{\tau} f(v + 1) + f(v + 2) \partial_{\tau} f(v)]
\]
\[
+ \frac{(\vec{x} - \vec{x}')^2}{4} \left[ f(v + 2) \partial_{\tau} f(v + 1)
\right.
\]
\[
+ \frac{1}{2} f(v + 1) \partial_{\tau} f(v + 2) + \frac{1}{2} f(v + 3) \partial_{\tau} f(v)
\]
\[
\left. \right\} \quad (A.2)
\]

\[
C_{31}(\tau - \tau', |\vec{x} - \vec{x}'|) = \frac{1}{2(4\pi)^{N-1} \beta^2} \left\{ \frac{N^2 - N - 2}{4} f(v + 1) f(v + 1)
\right.
\]
\[
- (N - 1) f(v + 1) \partial_{\tau}^2 f(v)
\]
\[
+ \frac{(\vec{x} - \vec{x}')^2}{4} \left[ 2 f(v + 2) \partial_{\tau}^2 f(v) + 2 f(v + 1) \partial_{\tau}^2 f(v + 1)
\right.
\]
\[
- (2N + 1) f(v + 2) f(v + 1)
\]
\[
+ \frac{(\vec{x} - \vec{x}')^4}{8} [f(v + 3) f(v + 1) + f(v + 2) f(v + 2)]
\]
(A.3)

\[
C_{32}(\tau - \tau', |\vec{x} - \vec{x}'|) = \frac{1}{2(4\pi)^{N-1} \beta^2} \left\{ \frac{N + 3}{4} f(v + 1) f(v + 1)
\right.
\]
\[
+ \frac{1}{2} f(v + 1) \partial_{\tau} f(v + 1) - \frac{1}{2} f(v + 1) \partial_{\tau}^2 f(v + 1)
\]
\[
- \frac{(\vec{x} - \vec{x}')^2}{8} [f(v + 3) f(v + 1) + f(v + 2) f(v + 2)]
\]
\[
\left. \right\} \quad (A.4)
\]

\[
C_{41}(\tau - \tau', |\vec{x} - \vec{x}'|) = \frac{1}{2(4\pi)^{N-1} \beta^2} \left\{ -f(v + 1) \partial_{\tau}^2 f(v) \right\}
\]
\[
(A.5)
\]

\[
C_{42}(\tau - \tau', |\vec{x} - \vec{x}'|) = \frac{1}{2(4\pi)^{N-1} \beta^2} \left\{ \frac{1}{2} \partial_{\tau} f(v + 1) \partial_{\tau} f(v + 1) + \frac{1}{2} f(v + 2) \partial_{\tau}^2 f(v) \right\}
\]
\[
(A.6)
\]

\[
C_{51}(\tau - \tau', |\vec{x} - \vec{x}'|) = \frac{1}{2(4\pi)^{N-1} \beta^2} \left\{ \partial_{\tau} f(v + 1) \partial_{\tau}^2 f(v) + \frac{1}{2} \partial_{\tau} f(v) \partial_{\tau}^2 f(v + 1)
\right.
\]
\[
+ \frac{1}{2} f(v + 1) \partial_{\tau}^2 f(v) - \frac{N + 1}{4} f(v + 2) \partial_{\tau} f(v)
\]
\[
- \frac{N + 1}{4} f(v + 1) \partial_{\tau} f(v + 1)
\]
\[
+ \frac{(\vec{x} - \vec{x}')^2}{4} \left[ f(v + 2) \partial_{\tau} f(v + 1) + \frac{1}{2} f(v + 3) \partial_{\tau} f(v)
\right.
\]
\[
\left. + \frac{1}{2} f(v + 1) \partial_{\tau} f(v + 2) \right\}
\]
\[
(A.7)
\]

\[
C_{52}(\tau - \tau', |\vec{x} - \vec{x}'|) = \frac{1}{2(4\pi)^{N-1} \beta^2} \left\{ \frac{1}{2} f(v + 1) \partial_{\tau} f(v + 1) \right\}
\]
\[
(A.8)
\]
Using equation (31), we have the high-temperature expansions of the correlators

\begin{align*}
C_{33}(\tau - \tau', |\vec{x} - \vec{x}'|) &= \frac{1}{2(4\pi)^{N-1}\beta^2} \left\{ -\frac{1}{2} f(v + 2) \partial_{\tau} f(v + 1) \right\} \\
C_{63}(\tau - \tau', |\vec{x} - \vec{x}'|) &= \frac{1}{2(4\pi)^{N-1}\beta^2} \left\{ 2\partial_{\tau} f(v) \partial_{\tau} f(v) + 2\partial_{\tau}^2 f(v) \right\} \\
&\quad - (N - 1) f(v + 1) \partial_{\tau}^2 f(v) - (N - 1) \partial_{\tau} f(v) \partial_{\tau} f(v + 1) \\
&\quad + \frac{N^2 - N - 4}{4} f(v + 1) f(v + 1) \\
&\quad + \frac{(\vec{x} - \vec{x}')^2}{2} \left\{ f(v + 1) \partial_{\tau}^2 f(v + 1) + \partial_{\tau} f(v + 1) \partial_{\tau} f(v + 1) \\
&\quad + f(v + 2) \partial_{\tau}^2 f(v + 2) + \partial_{\tau} f(v + 2) \partial_{\tau} f(v + 2) - \frac{2N + 1}{2} f(v + 2) f(v + 1) \right\} \\
&\quad + \frac{(\vec{x} - \vec{x}')^4}{8} \left\{ f(v + 2) f(v + 2) + f(v + 3) f(v + 1) \right\} \\
C_{62}(\tau - \tau', |\vec{x} - \vec{x}'|) &= \frac{1}{2(4\pi)^{N-1}\beta^2} \left\{ \frac{1}{2} f(v + 1) f(v + 1) \right\} \\
C_{63}(\tau - \tau', |\vec{x} - \vec{x}'|) &= \frac{1}{2(4\pi)^{N-1}\beta^2} \left\{ -\frac{1}{2} f(v + 1) \partial_{\tau}^2 f(v + 1) \\
&\quad - \frac{1}{2} \partial_{\tau} f(v + 1) \partial_{\tau} f(v + 1) + \frac{N + 3}{4} f(v + 2) f(v + 1) \\
&\quad - \frac{(\vec{x} - \vec{x}')^2}{8} \left\{ f(v + 3) f(v + 1) + f(v + 2) f(v + 2) \right\} \\
C_{64}(\tau - \tau', |\vec{x} - \vec{x}'|) &= \frac{1}{2(4\pi)^{N-1}\beta^2} \left\{ -\frac{1}{2} f(v + 2) f(v + 1) \right\} \\
C_{65}(\tau - \tau', |\vec{x} - \vec{x}'|) &= \frac{1}{2(4\pi)^{N-1}\beta^2} \left\{ \frac{1}{4} f(v + 2) f(v + 2) \right\}. \\
\end{align*}

**Appendix B. High-temperature expansion**

Using equation (31), we have the high-temperature expansions of the correlators

\begin{align*}
\Delta T_{0000}^2(x, 0) &= \frac{(N - 1) (N - 2) \Gamma^2((N - 1)/2)}{8\pi^{N-1} |x|^{2N}} \left( \frac{|x|}{\beta} \right)^2 \\
&\quad + e^{-2\pi |x|/\beta} \cos \left( \frac{2\pi \tau}{\beta} \right) \frac{(N - 2) \Gamma((N - 1)/2)}{\pi^{(N-3)/2} |x|^{2N}} \left( \frac{|x|}{\beta} \right)^{N/2} \\
&\quad \times \left[ 1 - \frac{3N(N + 2)}{16(N - 2)^2\pi} \left( \frac{\beta}{|x|} \right)^2 + \ldots \right] + \ldots \\
\Delta T_{0000}^2(x, 0) &= -\frac{x_0}{\beta} e^{-2\pi |x|/\beta} \sin \left( \frac{2\pi \tau}{\beta} \right) \frac{(N - 2) \Gamma((N - 1)/2)}{\pi^{(N-3)/2} |x|^{2N}} \\
&\quad \times \left( \frac{|x|}{\beta} \right)^{N/2 + 1} \left[ 1 - \frac{N(N - 3)}{32\pi} \left( \frac{\beta}{|x|} \right)^2 + \ldots \right] + \ldots \\
\Delta T_{00ij}^2(x, 0) &= \frac{N |x|^2}{\beta^2} \delta_{ij} - 2(N - 1) \frac{x_i x_j}{\beta^2} \frac{(N - 3) \Gamma^2((N - 1)/2)}{8\pi^{N-1} |x|^{2N}} \\
&\quad + e^{-2\pi |x|/\beta} \cos \left( \frac{2\pi \tau}{\beta} \right) \frac{(N - 2) \Gamma((N - 1)/2)}{\pi^{(N-3)/2} |x|^{2N}} \left( \frac{|x|}{\beta} \right)^{N/2} \\
&\quad \times \left[ 1 - \frac{3N(N + 2)}{16(N - 2)^2\pi} \left( \frac{\beta}{|x|} \right)^2 + \ldots \right] + \ldots \\
\end{align*}
\[
\Delta T^2_{0ij}(x,0) = \left[ \frac{|\vec{x}|^2}{\beta^2} \delta_{ij} - (N-1) \frac{x_i x_j}{\beta^2} \right] e^{-2\pi i |\vec{x}|/\beta} \cos \left( \frac{2\pi \tau}{\beta} \right) \frac{\Gamma((N-1)/2)}{\pi^{(N-3)/2} |\vec{x}|^{2N}} \left( \frac{\beta}{|\vec{x}|} \right)^{N/2} \\
\times \left[ 1 + \frac{(N-2)(N-4)}{16\pi} \left( \frac{\beta}{|\vec{x}|} \right) + \cdots \right] + \cdots. \tag{B.3}
\]

\[
\Delta T^2_{0jk}(x,0) = e^{-2\pi i |\vec{x}|/\beta} \sin \left( \frac{2\pi \tau}{\beta} \right) \frac{\Gamma((N-1)/2)}{\pi^{(N-3)/2} |\vec{x}|^{2N}} \left( \frac{\beta}{|\vec{x}|} \right)^{\frac{N}{2} - 1} \\
\times \left[ -(N-2) \frac{|\vec{x}|^2}{\beta^2} \delta_{jk} \left[ 1 + \frac{N(N-3)}{32\pi} \left( \frac{\beta}{|\vec{x}|} \right) + \cdots \right] \\
- \frac{|\vec{x}|^2}{\beta^2} \delta_{ij} \left[ 1 + \frac{N(N-2)}{16\pi} \left( \frac{\beta}{|\vec{x}|} \right) + \cdots \right] \right] + \cdots. \tag{B.4}
\]

\[
\Delta T^2_{ijkl}(x,0) = \frac{\Gamma((N-1)/2)}{8\pi^{N-5/2} |\vec{x}|^{2N} \beta^2} \left\{ (N^2 - 3N - 2) \frac{|\vec{x}|^2}{\beta} \delta_{ij} \delta_{kl} + 2 |\vec{x}|^2 \left( \delta_{ik} \delta_{jl} + \delta_{ij} \delta_{kl} \right) \\
- 2(N-1)(N-3) \left( \delta_{ij} x_k x_l + \delta_{kl} x_i x_j \right) \\
- 2(N-1) \left( \delta_{ik} x_j x_l + \delta_{ij} x_k x_l + \delta_{jl} x_i x_k + \delta_{jk} x_i x_l \right) + \frac{4(N-1)^2}{|\vec{x}|^2} x_i x_j x_k x_l \right\} \\
+ e^{-2\pi i |\vec{x}|/\beta} \cos \left( \frac{2\pi \tau}{\beta} \right) \frac{\Gamma((N-1)/2)}{\pi^{(N-3)/2} |\vec{x}|^{2N} \beta^2} \left( \frac{\beta}{|\vec{x}|} \right)^{N/2} \\
\times \left[ (N-2) \frac{|\vec{x}|^2}{\beta^2} \delta_{ij} \delta_{kl} \left[ 1 - \frac{(3N^2 + 6N + 32)}{16(N-2)\pi} \left( \frac{\beta}{|\vec{x}|} \right) + \cdots \right] \\
+ |\vec{x}|^2 \left( \delta_{ik} \delta_{jl} + \delta_{ij} \delta_{kl} \right) \left[ 1 + \frac{(N^3 - 3N^2 - 26N + 16)}{32(N-2)\pi} \left( \frac{\beta}{|\vec{x}|} \right) + \cdots \right] \right] \\
\times \left[ 1 + \frac{(N^2 + 10N - 8)}{16\pi} \left( \frac{\beta}{|\vec{x}|} \right) + \cdots \right] \\
- \left( \delta_{ik} x_j x_l + \delta_{ij} x_k x_l + \delta_{jl} x_i x_k + \delta_{jk} x_i x_l \right) \left[ 1 + \frac{(N^4 + 10N^2 - 28N + 32)}{32(N-2)\pi} \left( \frac{\beta}{|\vec{x}|} \right) + \cdots \right] \right] + \cdots. \tag{B.5}
\]

\[
\Delta T^2_{\mu
u\alpha\beta}(x,0) = \Delta T^2_{\mu
u\alpha\beta|T=0}(x,0) + \Delta T^2_{\mu
u\alpha\beta|T\neq0}(x,0). \tag{C.1}
\]

**Appendix C. Low-temperature expansion**

Using equation (42), we have the low-temperature expansions of the correlators with \( s^2 = |\vec{x}|^2 + \tau^2 \). We present the results for \( T = 0 \) and \( T \neq 0 \) separately:
Then, the temperature-dependent parts can be expanded as follows:

\[
\Delta T_{\mu\nu\alpha\beta}(T,0)(x,0) = -\frac{NT^2(N/2)\zeta(N)}{2\pi^N s^N \beta^N} \left( 1 - \frac{N^2}{s^2} \right) + \cdots
\]

(3.3)

\[
\Delta T_{\mu0i0}(T,0)(x,0) = \frac{N^2\zeta(N)(N-1)\tau x_i}{2\pi^N s^N + \frac{2N}{s^2}} + \cdots
\]

(4.4)

\[
\Delta T_{0ij0}(T,0)(x,0) = \frac{N^2\zeta(N)(N-2)\tau x_j}{2\pi^N s^N + \frac{2N}{s^2}} + \cdots
\]

(5.5)

\[
\Delta T_{00ij}(T,0)(x,0) = \frac{N^2\zeta(N)(N-1)\tau x_j}{2\pi^N s^N + \frac{2N}{s^2}} + \cdots
\]

(6.6)

\[
\Delta T_{\mu0ijkl}(T,0)(x,0) = \frac{-N^2\zeta(N)(N-1)\tau x_k}{2\pi^N s^N + \frac{2N}{s^2}} + \cdots
\]

(7.7)

\[
\Delta T_{\mu0ijkl}(T,0)(x,0) = \frac{-N^2\zeta(N)(N-1)\tau x_l}{2\pi^N s^N + \frac{2N}{s^2}} + \cdots
\]
