Abstract. In this contribution, we discuss the possibility of meta-stable supersymmetry (SUSY) breaking vacua in a perturbed Seiberg-Witten theory with Fayet-Iliopoulos (FI) term. We found meta-stable SUSY breaking vacua at the degenerated dyon and monopole singular points in the moduli space at the nonperturbative level.

Keywords: Supersymmetry breaking

THE MODEL

SUSY breaking at meta-stable vacua in various SQCD models has been intensively studied since the proposal of the ISS model [1]. The other interest is meta-stable SUSY breaking in perturbed Seiberg-Witten theories [2, 3, 4]. In the following, we focus on this possibility.

We consider four-dimensional $\mathcal{N} = 2$ $SU(N_c) \times U(1)$, $N_f$ flavors SQCD with FI term. Supersymmetry in the model is partially broken down to $\mathcal{N} = 1$ due to the presence of adjoint mass terms. The extra $U(1)$ part is necessary for the FI term and treated as cut-off theory with Landau pole $\Lambda$. With the help of the Seiberg-Witten solution, we can analyze the theory in exact way provided the Landau pole is very far away and the perturbation terms are very much smaller than the $SU(N_c)$ dynamical scale $\Lambda$. In the following, we focus on $N_c = N_f = 2$ case and show that there are SUSY breaking meta-stable minima in the full quantum level.

$\mathcal{N} = 1$ SUSY preserving deformation of $\mathcal{N} = 2$ SQCD

Let us consider a tree-level Lagrangian

$$\mathcal{L} = \mathcal{L}_{\text{SQCD}}^{\mathcal{N} = 2} + \mathcal{L}_{\text{soft}}.$$  

Here $\mathcal{L}_{\text{SQCD}}^{\mathcal{N} = 2}$ is the Lagrangian for $\mathcal{N} = 2$ $SU(2) \times U(1)$ super Yang-Mills with $N_f = 2$ massless fundamental hypermultiplets

$$\mathcal{L}_{\text{SQCD}}^{\mathcal{N} = 2} = \frac{1}{2 \pi} \text{Im} \left[ \text{Tr} \left\{ \tau_{22} \left( \int d^4 \theta \ A_2^r e^{-2 \psi} + \frac{1}{2} \int d^2 \theta \ W_2^2 \right) \right\} \right].$$

where $V_2, A_2$ and $V_1, A_1$ are vector and chiral superfields belonging to the $SU(2)$ and $U(1)$ vector multiplets respectively. The chiral superfields $Q_i^r$ and $\tilde{Q}_i^r$ are hypermultiplets that are in the fundamental and anti-fundamental representations of the $SU(2)$ gauge group ($r = 1, 2$ is the flavor index, and $I = 1, 2$ is the $SU(2)$ color index). $W$ is the $\mathcal{N} = 1$ superfield strength and $\tau_{ij}$ are complex gauge couplings.

The second term $\mathcal{L}_{\text{soft}}$ is the soft SUSY breaking term given by

$$\mathcal{L}_{\text{soft}} = \int d^2 \theta \left( \mu_2 \text{Tr} (A_2^2) + \frac{1}{2} \mu_1 A_1^2 + \lambda A_1 \right) + h.c.$$  

In $\mathcal{L}_{\text{soft}}$, $\mu_1, \mu_2$ are masses corresponding to $U(1)$ and $SU(2)$ part of the adjoint scalars and $\lambda$ is the FI parameter. In the absence of $\mathcal{L}_{\text{soft}}$, the gauge symmetry is broken as $SU(2) \times U(1) \rightarrow U(1)_c \times U(1)$ on the Coulomb branch

$$g_r = \tilde{g}_r = 0, \quad A_2 = \begin{pmatrix} a_2 & 0 \\ 0 & -a_2 \end{pmatrix}, \quad A_1 = a_1,$$  

where $g, \tilde{g}$ are hypermultiplet scalars. Once we turn on $\mathcal{L}_{\text{soft}}$, there are SUSY vacua on the Coulomb and Higgs branches. We are going to investigate the quantum effective action on the Coulomb branch.
QUANTUM THEORY

The exact low energy effective Lagrangian is described by light fields, the $SU(2)$ dynamical scale $\Lambda$, the Landau pole $\Lambda_L$, the masses $\mu_i$ ($i = 1, 2$) and the FI parameter $\lambda$. If the perturbation terms are much smaller than the dynamical scale $\Lambda$, the effective Lagrangian $\mathcal{L}_{\text{exact}}$ is given by

$$\mathcal{L}_{\text{exact}} = \mathcal{L}_{\text{SUSY}} + \mathcal{L}_{\text{pert}} + \mathcal{O}(\mu_i^2, \lambda).$$  \hspace{1cm} (5)

Here the first term $\mathcal{L}_{\text{SUSY}}$ describes an $\mathcal{N} = 2$ SUSY Lagrangian containing full quantum corrections. The second term $\mathcal{L}_{\text{pert}}$ includes the masses and the FI terms in the leading order.

First we consider the general formulas for the effective Lagrangian $\mathcal{L}_{\text{SUSY}}$. The Lagrangian $\mathcal{L}_{\text{SUSY}}$ is given by two parts, vector multiplet part $\mathcal{L}_{\text{VM}}$ and hypermultiplet part $\mathcal{L}_{\text{HM}}$.

$$\mathcal{L}_{\text{SUSY}} = \mathcal{L}_{\text{VM}} + \mathcal{L}_{\text{HM}}.$$  \hspace{1cm} (6)

The $\mathcal{L}_{\text{VM}}$ part consists of $U(1)_c$ and $U(1)$ vector multiplets. The effective Lagrangian for these vector multiplets is

$$\mathcal{L}_{\text{VM}} = \frac{1}{4\pi} \text{Im} \sum_{i,j=1}^{2} \left[ \int d^4 \theta \left( \frac{\partial \mathcal{F}}{\partial A_i} A_j^\dagger \right) + \frac{1}{2} \int d^2 \theta \, \tau_{ij} W_i W_j \right].$$  \hspace{1cm} (7)

where $\mathcal{F} = \mathcal{F}(A_2, A_1, \Lambda, \Lambda_L)$ is a prepotential as will be discussed below. The effective gauge coupling $\tau_{ij}$ is defined by $\tau_{ij} = \frac{\partial^2 \mathcal{F}}{\partial a_i \partial a_j}$ with moduli $a_i$. The hypermultiplet part $\mathcal{L}_{\text{HM}}$ is

$$\mathcal{L}_{\text{HM}} = \int d^4 \theta \left[ M'_r e^{2n_r V_{2D} + 2n_r V_2 + 2n_i M'} + \tilde{M}_r e^{-2n_r V_{2D} - 2n_r V_2 - 2n_i M'} \right]$$

$$+ \sqrt{2} \int d^2 \theta \left[ \tilde{M}_r (n_r A_{2D} + n_r A_2 + n_r A_1) M' + h.c. \right]$$  \hspace{1cm} (8)

where $M', \tilde{M}_r$ are chiral superfields and $V_{2D}, A_{2D}$ are dual variables of $V_2, A_2$. These hypermultiplets correspond to the light BPS dyons, monopoles and quarks, which are specified through the appropriate quantum numbers $(n_r, n_m)_r$. Here $n_r$ and $n_m$ are the electric and magnetic charges of $U(1)_c$, respectively, whereas $n$ is the $U(1)$ charge. The potential is a function of $M, \tilde{M}, a_1, a_2$. We found stationary points along $M, \tilde{M}$ directions at (1) $M = \tilde{M} = 0$ and (2) $M \neq 0, \tilde{M} \neq 0$. The potential value at each stationary points are evaluated as

$$V(a_2, a_1) = U,$$  \hspace{1cm} (9)

$$V(a_2, a_1) = U - 4S \mathcal{M}^4,$$  \hspace{1cm} (10)

where $U = U(a_1, a_2), S = S(a_1, a_2) > 0$ are functions of $a_1, a_2$ and $\mathcal{M} = |M| = |\tilde{M}|$. The stationary point $\mathcal{F}(a_2, a_1, \Lambda, \Lambda_L) = \mathcal{F}^{(\text{SW})}_{SU(2)}(a_2, m, \Lambda)$ at $m = \sqrt{2} a_1$, where $\mathcal{F}^{(\text{SW})}_{SU(2)}$ is the prepotential for $SU(2)$ massive SQCD with common mass $m = \sqrt{2} a_1$. The constant $C$ is a free parameter which is used to fix the Landau pole $\Lambda$ to the appropriate value.

The singular points on the moduli space are determined by a cubic polynomial. The solutions of the cubic polynomial give the positions of the singular points in the $u$-plane. In the case $N_c = N_f = 2$ with a common hypermultiplet mass $m$, which is regarded as the modulus $\sqrt{2} a_1$ here, the solution obtained as

$$u_1 = -m \Lambda - \frac{\Lambda^2}{8} , \quad u_2 = m \Lambda - \frac{\Lambda^2}{8} , \quad u_3 = m^2 + \frac{\Lambda^2}{8}.$$

The singular points correspond to dyons, a monopole and a quark. The behavior of the singularity flow along $a_1$ direction can be found in [6]. The stationary point of the potential along the $a_1$ direction is a difficult task and we need the help of numerical analysis.

Let us start from the $\mu_1 = \lambda = 0$ case. Fig. [1] shows the global structure of the potential along the $\text{Re}(a_1)$ direction. As a result, we found the global SUSY minima at $a_1 = 0$ in the degenerated dyon and monopole singular points.

Next, let us turn on $\mu_1$ and $\lambda$. In the presence of the soft term, the gauge dynamics favors the monopole and the dyon points at $a_1 = 0$ as SUSY vacua besides the runaway vacua. It implies that if we add $\mu_1 \neq 0, \lambda \neq 0$ terms which produce a vacuum at a point different from $a_1 = 0$ at the classical level, SUSY is dynamically broken as a consequence of the discrepancy of SUSY conditions between the classical and the quantum theories. Actually, $\mu_1 \lambda$.

We fix $C = 4\pi i$ which implies $\Lambda_L \sim 10^{17-18} \Lambda$. 

\footnote{We fix $C = 4\pi i$ which implies $\Lambda_L \sim 10^{17-18} \Lambda$.}
turning on the mass $\mu_1$ and the FI parameter $\lambda$ realizes such a situation. In this case, the classical vacuum is at $a_1 = -\lambda / \mu_1$, different from the point $a_1 = 0$ which the dynamics favors. A resultant SUSY breaking vacuum is realized at non-zero value of $a_1$. This is very similar to the SUSY breaking mechanism discussed in the Izawa-Yanagida-Intriligator-Thomas model in $\mathcal{N} = 1$ SUSY gauge theory [8, 9]. We show a schematic picture of our situation in Fig. 2.

Let us see in detail how this works for non-zero values of $\mu_1$, $\mu_2$ and $\lambda$. Fig. 3 shows the evolution of the potential energies at the monopole point $V^3_{\text{min}}$ for several values of $\lambda$ as a function of $\text{Re}(a_1)$ with $\mu_1 = \mu_2 = 0.1$. The potential minimum is no longer realized at $a_1 = 0$, but the location is shifted to negative values of $\text{Re}(a_1)$ as is expected from the discussion in the previous paragraph. Furthermore, the potential energy has a non-zero value and therefore SUSY is dynamically broken. We find that the potential energies at the left and right dyon singular points also have the same structure. A qualitative picture of the evolutions of the potential minima is depicted in Fig. 4.
