WEIGHTED SUBSPACE DESIGNS FROM $q$-POLYMATROIDS

EIMEAR BYRNE, MICHELA CERIA, SORINA IONICA, AND RELINDE JURRIUS

Abstract. The Assmus-Mattson Theorem gives a way to identify block designs arising from codes. This result was broadened to matroids and weighted designs by Britz et al. in 2009. In this work we present a further two-fold generalisation: first from matroids to polymatroids and also from sets to vector spaces. To achieve this, we study the characteristic polynomial of a $q$-polymatroid and outline several of its properties. We also derive a MacWilliams duality result and apply this to establish criteria on the weight enumerator of a $q$-polymatroid for which dependent spaces of the $q$-polymatroid form the blocks of a weighted subspace design.

1. Introduction

The characteristic polynomial of a matroid is a well studied object. It was first introduced as a matroid generalisation of the chromatic polynomial of a graph. It arises in critical problems, analyses of the Tutte polynomial, and is the subject of numerous identities [22] For a thorough treatment of the subject see [32, 34], for example.

In combinatorics, the concept of a $q$-analogue can be viewed as a generalisation from sets to vector spaces. Recently, the $q$-analogue of a matroid has been studied [20]. A generalisation of this is a $q$-polymatroid [18, 19, 29].

Similar to classical matroids, there are many interesting connections between $q$-(poly)matroids and rank-metric codes. In this paper we develop the theory of the characteristic polynomial of a $q$-polymatroid. We show the relation between the characteristic polynomial of a polymatroid and its dual, establishing a MacWilliams-like identity for $q$-polymatroids. In a similar line of research, Shiromoto [29] established a $q$-analogue of Greene’s theorem.

Another motivation to study the characteristic polynomial is to establish a $q$-analogue of the Assmus-Mattson Theorem [1]. This theorem gives a criterion for identifying a $t$-design as a collection of supports of codewords of fixed weight in a linear code. Since its publication in 1969 it has seen a number of generalisations [10, 24] and has been used widely to obtain new constructions of designs [16, 28]. In one of these results [5], the authors define a weighted $t$-design as a generalisation of a classical $t$-design and give criteria for identifying such an object among the dependent sets of a matroid of a fixed cardinality. A weighted $t$-design is a collection of subsets $B$ of a fixed cardinality $k$ chosen from an $n$-set of points $P$ together with a function $f$ defined on $B$ such that for any $t$-set $T \subset P$ the sum $\sum_{B \in B: T \subset B} f(B)$ is independent of $T$. In the case that $f(B) = 1$ for every block $B \in B$, the weighted $t$-design is an ordinary design.

In this paper, we generalise the results of [5] to $q$-polymatroids, which is a two-fold generalisation: first from matroids to polymatroids and also from sets to vector spaces. Hence the results presented here give a $q$-analogue of their result. The $q$-analogue of a weighted $t$-design is a weighted subspace design; in the definition shown above we replace the collection of subsets $B$ with a collection of subspaces of a fixed dimension $k$ and $T$ with a $t$-dimensional subspace.

In Section 2 we study $q$-polymatroids and the properties of $q$-polymatroids that are necessary for this work. In Section 3 we outline properties of the characteristic polynomial of a $q$-polymatroid that will be used later and in Section 4 look at the case of $q$-polymatroids arising from matrix codes. In Section 5 we give a version of the MacWilliams duality result for $q$-polymatroids. In Section 6 we give criteria for identifying when the dependent spaces of a

Key words and phrases. $q$-analogue, $q$-polymatroid, weighted subspace design, characteristic polynomial.
\( q \)-polymatroid are the blocks of a weighted \( t \)-subspace design.

**Notation 1.** Throughout, we let \( n \) denote a fixed positive integer and we will let \( q \) denote a fixed prime power. We let \( E \) denote an \( n \)-dimensional vector space over the finite field \( \mathbb{F}_q \) of order \( q \). We let \( \mathcal{L}(E) \) denote the lattice of all subspaces of \( E \), ordered by inclusion, which we denote by \( \leq \). We will write \( U < V \) for \( U, V \leq E \) if \( U \) is strictly contained in \( V \). The join of a pair of subspaces is their vector space sum and the meet of a pair of subspaces is their intersection.

2. \( q \)-Polymatroids

\( q \)-Polymatroids and their connections to linear codes were introduced in [19] and [29]. Their properties have been further developed in [18]. In our presentation, we will not assume that \( q \)-polymatroids are representable, that is, we will not assume that the \( q \)-polymatroids under consideration here are constructed from rank-metric codes over \( \mathbb{F}_q \). We use the following definition of a \( q \)-polymatroid from [29], since it suits our purposes to have an integer valued function in what follows.

**Definition 2.** A \((q, r)\)-polymatroid is a pair \( M = (E, \rho) \) for which \( r \in \mathbb{N}_0 \) and \( \rho \) is a function \( \rho : \mathcal{L}(E) \longrightarrow \mathbb{N}_0 \) satisfying the following axioms.

(R1) For all \( A \leq E \), \( 0 \leq \rho(A) \leq r \dim A \).

(R2) For all \( A, B \leq E \), if \( A \leq B \), then \( \rho(A) \leq \rho(B) \).

(R3) For all \( A, B \leq E \), \( \rho(A + B) + \rho(A \cap B) \leq \rho(A) + \rho(B) \).

Every \((q, r)\)-polymatroid is also a \((q, r')\)-polymatroid for any \( r' \geq r \). Hence, all the definitions below involving \( r \) depend on the choice of \( r \). If it is not necessary to specify \( r \), we will simply refer to such an object as a \( q \)-polymatroid. If we need to specify the \( q \)-polymatroid \( M \), we denote its rank function by \( \rho_M \). Note that a \((q, 1)\)-polymatroid is a \( q \)-matroid. Conversely, if we consider a \( q \)-matroid as a \((q, r)\)-polymatroid, we will always take \( r = 1 \). In order to stress in a stronger way the distinction between matroids and their \( q \)-analogues, we use the terminology “classical matroids” for matroids.

Recall that a lattice isomorphism between a pair of lattices \((\mathcal{L}_1, \vee_1, \wedge_1), (\mathcal{L}_2, \vee_2, \wedge_2)\) is a bijective function \( \varphi : \mathcal{L}_1 \longrightarrow \mathcal{L}_2 \) that preserves the meet and join, that is, for all \( x, y \in \mathcal{L}_1 \) we have that \( \varphi(x \wedge_1 y) = \varphi(x) \wedge_2 \varphi(y) \) and \( \varphi(x \vee_1 y) = \varphi(x) \vee_2 \varphi(y) \). It is well known that reversing the ordering of a lattice gives again a lattice, with the meet and join interchanged. Combining this operation with a lattice isomorphism gives a lattice anti-isomorphism. Formally, a lattice anti-isomorphism between a pair of lattices is a bijective function \( \psi : \mathcal{L}_1 \longrightarrow \mathcal{L}_2 \) that is order-reversing and interchanges the meet and join, that is, for all \( x, y \in \mathcal{L}_1 \) we have that \( \psi(x \wedge_1 y) = \psi(x) \vee_2 \psi(y) \) and \( \psi(x \vee_1 y) = \psi(x) \wedge_2 \psi(y) \). See [2, Pages 3–4]. We hence define a notion of equivalence and duality between \( q \)-polymatroids.

**Definition 3.** Let \( E_1, E_2 \) be \( \mathbb{F}_q \)-linear spaces. Let \( M_1 = (E_1, \rho_1) \) and \( M_2 = (E_2, \rho_2) \) be \( q \)-polymatroids. We say that \( M_1 \) and \( M_2 \) are lattice-equivalent if there exists a lattice isomorphism \( \varphi : \mathcal{L}(E_1) \longrightarrow \mathcal{L}(E_2) \) such that \( \rho_1(A) = \rho_2(\varphi(A)) \) for all \( A \leq E_1 \). In this case we write \( M_1 \cong M_2 \).

**Notation 4.** Let \( F \) be an \( \mathbb{F}_q \)-vector space. We denote by \( \perp(F) \) a fixed anti-isomorphism on \( \mathcal{L}(F) \), which we require to be an involution. For any subspace \( U \leq F \) we denote by \( U^\perp(F) \) the image of \( U \) under \( \perp(F) \), which we call the dual of \( U \) in \( F \). Note that since an anti-isomorphism preserves the length of intervals, we have for any \( U \leq F \) that \( \dim(U^\perp(F)) = \dim(F) - \dim(U) \).

In the case \( F = E \), we drop the \((E)\) and we simply write \( \perp := \perp(E) \). For any subspace \( U \leq E \), we write \( U^\perp := U^\perp(E) \).

**Remark 5.** The notion of lattice-equivalence in Definition 3 is not the same as the definition of equivalence of \( q \)-polymatroids given in [18] and [19]. Indeed, in [18] and [19] two
$q$-polymatroids $(E_1, \rho_1)$ and $(E_2, \rho_2)$ are said to be **equivalent** if there exists an $F_q$-linear isomorphism $\tau : E_1 \to E_2$ such that $\rho_1(A) = \rho_2(\tau(A))$ for all $A \subseteq E_1$. Since every vector space isomorphism induces a lattice isomorphism, equivalence implies lattice-equivalence for $q$-polymatroids. In particular, every non-degenerate symmetric bilinear form $b_F$ on $F$ induces a lattice anti-isomorphism, hence our definition of dual implies the usual definition of orthogonal complement for $q$-matroids.

The dual $q$-polymatroid was defined in [19, 29].

**Definition 6.** Let $M = (E, \rho)$ be a $(q, r)$-polymatroid. For every subspace $A \subseteq E$, define $\rho^*(A) := r \dim(A) - \rho(E) + \rho(A^\perp)$. Then $M^* := (E, \rho^*)$ is a $(q, r)$-polymatroid called the **lattice-dual** of $M$.

We call $M^*$ the **dual** of $M$. As noted in [18], the definition of the dual of $M$ depends on the choice of anti-isomorphism on $E$, but all such choices yield equivalent duals. We prove this for our more general notions of lattice-equivalence and lattice-duality. The following is a generalisation of [18, Theorem 2.8].

**Lemma 7.** Let $M = (E, \rho)$ be a $(q, r)$-polymatroid and let $M' = (E, \rho')$ be a $(q, r)$-polymatroid that is lattice-equivalent to $M$. Let $\perp_1, \perp_2$ be a pair of anti-isomorphisms on $\mathcal{L}(E)$. Let $M^*$ and $M'^*$ be the duals of $M$ with respect to $\perp_1$ and $\perp_2$, respectively. Then $M^* \cong M'^*$ and $M'^* \cong M^*$.

**Proof.** For the first part, notice that the proof of [19, Proposition 3.7] carries over directly from $F_q$-isomorphisms to lattice-(anti-)isomorphisms. We include it here for completeness. Let $\varphi : \mathcal{L}(E) \to \mathcal{L}(E)$ be the isomorphism such that $\rho(A) = \rho'(\varphi(A))$ for all $A \subseteq E$. Let $\psi : \mathcal{L}(E) \to \mathcal{L}(E)$ be the isomorphism $\psi := \perp_1 \circ \varphi \circ \perp_2$. Then

$$\rho^*(A) = r \dim(A) - \rho(E) + \rho(A^\perp) = r \dim(A) - \rho(E) + \rho'(\varphi(A^\perp)) = r \dim(\psi(A)) - \rho'(\psi(E)) + \rho'(\psi(A^\perp)) = \rho'^*(\psi(A)).$$

This shows that $M^* \cong M'^*$. For the second statement we proceed in a similar way. Let $\phi : \mathcal{L}(E) \to \mathcal{L}(E)$ be the lattice isomorphism $\phi := \perp \circ \varphi \circ \perp$, so $\perp = \phi \circ \perp$. Then

$$\rho^*(A) = r \dim(A) - \rho(E) + \rho(A^\perp) = r \dim(\phi(A)) - \rho(\phi(E)) + \rho(\phi(A^\perp)) = \rho^*(\phi(A)).$$

This shows that $M^* \cong M'^*$. $\square$

Note that $M^{**} = M$ is an equality, because we assume the anti-isomorphism $\perp$ to be an involution.

It is easy to see that for a map $\rho : \mathcal{L}(E) \to \mathbb{N}_0$ satisfying the axioms (R1)-(R3), the restriction of that map to $\mathcal{L}(T)$, for each subspace $T \subseteq E$, also yields a $q$-polymatroid.

**Definition 8.** Let $M = (E, \rho)$ be a $(q, r)$-polymatroid and let $T \leq E$. For every subspace $A \subseteq T$, define $\rho_{M|T}(A) := \rho(A)$. Then $M|T := (T, \rho_{M|T})$ is a $(q, r)$-polymatroid called the **restriction** of $M$ to $T$.

Another way to construct a new $q$-polymatroid from an existing one is via contraction. It was proven in [18, Theorem 5.2] that this gives in fact a $q$-polymatroid.

**Definition 9.** Let $M = (E, \rho)$ be a $(q, r)$-polymatroid and let $T \leq E$. We define the map $\rho_{M|T} : \mathcal{L}(E/T) \to \mathbb{Z}$
via \( \rho_{M/T}(A/T) = \rho(A) - \rho(T) \). Then \( M/T := (E/T, \rho_{M/T}) \) is a \((q,r)\)-polymatroid called the \textbf{contraction} of \( T \) \textbf{from} \( M \).

It will sometimes be more convenient for us to use the slightly less commonly used definition of \textit{contraction} to a \textit{subspace}.

\textbf{Definition 10.} Let \( M = (M, \rho) \) be a \((q,r)\)-polymatroid and let \( X \leq E \). We denote by \( M.X \) the \( q \)-polymatroid \( M.X := (E/X^\perp, \rho_{E/X^\perp}) \). We call \( M.X \) the \textbf{contraction} of \( M \) \textbf{to} \( X \).

In the language of classical matroids, the contraction of \( M \) to \( X \) is the contraction of \( E - X \) from \( M \), that is \( M.X = M/(E - X) \) (see [26, Chapter 3]). In the \( q \)-analogue we have \( M.X := M/X^\perp \).

The following duality result is a straightforward extension of [20, Theorem 60]. It relates the contraction of a \( M \)-polymatroid to a restriction of its dual \( M \)-polymatroid. We will make good use of this in Section 6, where we give a construction of weighted subspace designs from \( q \)-polymatroids.

\textbf{Lemma 11.} Let \( M = (E, \rho) \) be a \((q,r)\)-polymatroid and let \( T \) be a subspace of \( E \). Then,

\[
M^*/T \cong (M[T^\perp]*)_T \quad \text{and} \quad (M/T)^* \cong M^*[T^\perp].
\]

\textbf{Proof.} Let \( \phi : \mathcal{L}(E/T) \to \mathcal{L}(T^\perp) \) be defined by \( \phi(X/T) = (X^\perp)^⊥(T^\perp) \), for each \( X \leq E \) such that \( T \leq X \) (in which case \( X^\perp \leq T^\perp \)). This map is the composition of two anti-isomorphisms: the anti-isomorphism between intervals \( [T, E] \) and \([0, T^\perp]\) induced by \( ⊥(E) \), followed by the anti-isomorphism \( ⊥(T^\perp) \) on \( \mathcal{L}(T^\perp) \). Hence \( \phi \) is a lattice isomorphism.

Let \( A \) be a subspace of \( E \) satisfying \( T \leq A \leq E \). We claim that \( \rho_{M^*/T}(A/T) = (\rho_{M[T^\perp]^*}(\phi(A/T))) \). Indeed, we have that:

\[
\rho_{M^*/T}(A/T) = \rho^*(A) - \rho^*(T) = r \dim(A) - \rho(T^\perp) + \rho(A^\perp) - r \dim(T) = r \dim(A/T) - \rho_{M[T^\perp]^*}(T^\perp) + \rho_{M[T^\perp]^*}(A^\perp) = (\rho_{M[T^\perp]^*}(\phi(A/T))).
\]

This shows that \( M^*/T \cong (M[T^\perp]*)_T \). That \( (M/T)^* \cong M^*[T^\perp] \) holds can be seen by replacing \( M \) with \( M^* \) in the previous identity, taking duals and applying Lemma 7. \( \square \)

\textbf{Remark 12.} In fact, the above result holds even in terms of equivalence in the stronger sense [18, Definition 2.6 (b)], and not only lattice-equivalence, as was shown in Theorem 5.3 of the same paper. Note that in establishing the equivalence of these \( q \)-polymatroids, the vector space isomorphism depends on the choice of the bilinear form arising in the construction of the lattice isomorphism.

Having established duality, restriction and contraction in terms of the rank function, we now introduce independent spaces.

\textbf{Definition 13.} Let \( I \leq E \) and let \( M = (E, \rho) \) be a \((q,r)\)-polymatroid. We say that \( I \) is an \textbf{independent space} of \( M \) if \( \rho(I) = r \dim I \). A subspace that is not independent is called a \textbf{dependent space} of \( M \). We call \( C \leq E \) a \textbf{circuit} of \( M \) if it is a minimal dependent space with respect to inclusion. We call \( T \leq E \) a \textbf{cocircuit} of \( M \) if it is a circuit of \( M^* \).

For \( q \)-matroids, the following result is (I2) of the independence axioms (see [9, Definition 7]). We show that this holds for \( q \)-polymatroids.

\textbf{Lemma 14.} Let \( M = (E, \rho) \) be a \((q,r)\)-polymatroid and let \( I \leq E \) be an independent space of \( M \). Then every subspace of \( I \) is independent.
Proof. Since $I$ is independent, we have $\rho(I) = r \dim(I)$. Let $J, J'$ be subspaces of $I$ such that $I$ is a direct sum of $J$ and $J'$. By (R1) and applying semimodularity (R3) to $J$ and $J'$ we get

$$r \dim(J) + r \dim(J') \geq \rho(J) + \rho(J') \geq \rho(J + J') + \rho(J \cap J')$$

$$= \rho(I) = r \dim(I) = r(\dim(J) + \dim(J')).$$

Since $\rho(J) \leq r \dim(J)$ and $\rho(J') \leq r \dim(J')$ we must have that $\rho(J) = r \dim(J)$ and $\rho(J') = r \dim(J')$ and the result follows. \hfill $\square$

From the above lemma, it follows that $C \leq E$ is a circuit of a $q$-polymatroid if it is a dependent space whose proper subspaces are all independent. If $J$ is a maximal independent subspace of $A \leq E$, then $\rho(A) = \rho(J)$; for $q$-matroids this follows directly from the cryptomorphism between independent spaces and rank [20, Theorem 8], for $q$-polymatroids this was shown in [17, Theorem 4.2].

The next lemma considers what happens to independent spaces and circuits under contraction of an independent space.

Lemma 15. Let $M = (E, \rho)$ be a $(q, r)$-polymatroid and let $I \leq E$ be an independent space of $M$. Let $I \leq A \leq E$. Then $A$ is independent in $M$ if and only if $A/I$ is independent in $M/I$. Moreover, if $A$ is a circuit in $M$, then $A/I$ is a circuit in $M/I$.

Proof. Let $A$ be independent in $M$. Then

$$r \dim(A/I) = r \dim(A) - r \dim(I) = \rho(A) - \rho(I) = \rho_{M/I}(A/I),$$

hence $A/I$ is an independent space of $M/I$. Conversely, if $A/I$ is independent in $M/I$, then

$$r \dim(A) - r \dim(I) = r \dim(A/I) = \rho_{M/I}(A/I) = \rho(A) - \rho(I) = \rho(A) - r \dim(I),$$

so $\rho(A) = r \dim(A)$.

Let $A$ be a circuit in $M$. Any proper subspace of $A/I$ has the form $B/I$ for some unique $I \leq B < A$. Since $A$ is a circuit, $A/I$ is a dependent space in $M/I$, and $B$ is an independent space of $M$. Therefore $B/I$ is independent and so $A/I$ is a circuit of $M/I$. \hfill $\square$

We conclude this section with some examples. These are from [20, Example 4] and [18, Example 4.8(a)].

Example 16 (The uniform $q$-Matroid). Let $k$ be a positive integer, $k \leq n$. The uniform $q$-matroid is the $q$-matroid $M = (E, \rho)$ with rank function defined as follows:

$$\rho(U) := \begin{cases} \dim(U) & \text{if } \dim(U) \leq k, \\ k & \text{if } \dim(U) > k. \end{cases}$$

We denote this $q$-matroid by $U_{k,n}$.

Example 17 (The Vámos $q$-Matroid). This $q$-matroid is constructed over $\mathcal{L}(\mathbb{F}_q^8)$. Choose the canonical basis for $\mathbb{F}_q^8$ denoted by $e_1, \ldots, e_8$. Consider the following collection of subspaces.

$$C := \{\langle e_1, e_2, e_3, e_4 \rangle, \langle e_1, e_2, e_5, e_6 \rangle, \langle e_3, e_4, e_5, e_6 \rangle, \langle e_3, e_4, e_7, e_8 \rangle, \langle e_5, e_6, e_7, e_8 \rangle, \langle e_5, e_6, e_7, e_8 \rangle \}.$$

For each $A \leq \mathbb{F}_q^8$, we define $\rho(A)$ as follows:

$$\rho(A) := \begin{cases} \dim(A) & \text{if } \dim(A) \leq 3, \\ 3 & \text{if } A \in C, \\ 4 & \text{if } \dim(A) \geq 4 \text{ and } A \notin C. \end{cases}$$

It can be shown that $\rho$ is the rank function of a $q$-matroid whose set of circuits of minimum dimension is the set $C$. 5
where \( n \) coefficient counts the number of \( J \) trivially with \( i \) and \( j \), respectively, satisfying \( I \cap J = \emptyset \) and \( i + j \leq k \). Then, the number of \( k \)-dimensional subspaces of \( E \) that contain \( I \) and meet trivially with \( J \) is

\[
\sum_{s=0}^{j} (-1)^s q^{s(2)} \binom{n-i-s}{s} q^{j-k-i} \binom{n-i-j}{k-i-s} \]  

where \( n \) is the dimension of \( E \).

In the above Lemma 20, we note another identity. That the right-hand side counts the number of \( k \)-dimensional subspaces of \( E \) that contain \( I \) and meet trivially with \( J \) was already observed, for example, in [15, Lemma 3], but is generally well-known. That this number is also given by the left-hand side formula can be established using Möbius inversion.
3.2. The Characteristic Polynomial. We now introduce the characteristic polynomial. First, we give another definition, which originates in weight enumeration of linear codes.

Definition 21. Let $M$ be a $(q,r)$-polymatroid with ground-space $E$. For each $A \subseteq E$ we define
\[
\ell_M(A) := \rho_M(E) - \rho_M(A).
\]

By the definition of the rank function of a $q$-polymatroid, for each subspace $A$ of $E$ we see that $\ell_M(A)$ is non-negative integer in $\{0, \ldots, \rho_M(E)\}$.

Notation 22. For the remainder, we fix $r$ to be a positive integer and we let $M$ denote a fixed $(q,r)$-polymatroid $M = (E, \rho)$. We write $\ell := \ell_M$ and $\rho := \rho_M$. For the dual $q$-polymatroid, we write $\ell^* := \ell_{M^*}$ and $\rho^* := \rho_{M^*}$.

Definition 23. The characteristic polynomial of $M$ is the polynomial in $\mathbb{Z}[z]$ defined by
\[
p(M; z) := \sum_{X: X \leq E} \mu(0, X) z^{\ell(X)},
\]
where $\mu$ is the Möbius function of the subspace lattice.

For the case $E = \{0\}$, we have $p(M; z) = 1$. If $E \neq \{0\}$, then $p(M; 1) = 0$ and so, unless $p(M; z)$ is identically zero, $z - 1$ is a factor of it in $\mathbb{Z}[z]$.

For a $(q,r)$-polymatroid $M$, we have
\[
p(M; z) := \sum_{j=0}^{n} (-1)^j q^j \sum_{X \leq E, \dim(X) = j} z^{\ell(X)}.
\]

Example 24. We calculate the characteristic polynomial of the Vámos $q$-matroid of Example 17. From the rank function it follows that:
\[
\ell(X) = \begin{cases} 
4 - \dim(X) & \text{if } \dim(X) \leq 3, \\
1 & \text{if } X \in \mathcal{C}, \\
0 & \text{if } \dim(X) \geq 4 \text{ and } X \notin \mathcal{C}.
\end{cases}
\]

We treat the calculations of the coefficients by the powers of $z$. For the coefficient of $z^4$ we only have $X \leq E$ with $\dim X = 0$, i.e., the zero space. Then $\mu(0, X) = \mu(0, 0) = 1$ and we get the term $z^4$. For $z^3$ and $z^2$ we get
\[
\sum_{\dim X = 1} \mu(0, X) z^{\ell(X)} = - \left[ \begin{array}{c} 8 \\ 1 \\
\end{array} \right] q z^3, \quad \sum_{\dim X = 2} \mu(0, X) z^{\ell(X)} = q \left[ \begin{array}{c} 8 \\ 2 \\
\end{array} \right] q z^2.
\]

For the coefficient of $z$ we have to consider the five circuits of dimension 4 and all spaces of dimension 3, which is
\[
5q^6 - q^3 \left[ \begin{array}{c} 8 \\ 3 \\
\end{array} \right] q.
\]

Finally, the constant term is determined by all spaces of dimension 4 that are not circuits, plus all spaces of higher dimension:
\[
q^6 \left( \begin{array}{c} 8 \\ 4 \\
\end{array} q - 5 \\
\end{array} - q^{10} \left[ \begin{array}{c} 8 \\ 5 \\
\end{array} q + q^{15} \left[ \begin{array}{c} 8 \\ 6 \\
\end{array} q \right] - q^{21} \left[ \begin{array}{c} 8 \\ 7 \\
\end{array} q \right] + q^{28} \right) = q^6 \left( \begin{array}{c} 8 \\ 4 \\
\end{array} q - 5 - q^4 \left[ \begin{array}{c} 8 \\ 3 \\
\end{array} q \right] + q^9 \left[ \begin{array}{c} 8 \\ 2 \\
\end{array} q \right] - q^{15} \left[ \begin{array}{c} 8 \\ 1 \\
\end{array} q \right] + q^{22} \right).
\]

Adding all terms gives the characteristic polynomial of the Vámos $q$-matroid. For example, for $q = 2$, we have $p(M; z) = z^4 - 255z^3 + 21590z^2 - 776920z + 755584 = (z - 1)(z^3 - 254z^2 + 21336z - 755584)$.

It is easily checked that the characteristic polynomial is an invariant of the lattice-equivalence class of a matroid.

Lemma 25. Let $E_1, E_2$ be $\mathbb{F}_q$-linear spaces. Let $M_1 = (E_1, \rho_1)$ and $M_2 = (E_2, \rho_2)$ be a pair of lattice-equivalent $q$-polymatroids. Then $p(M_1; z) = p(M_2; z)$. 

Let \( \bar{\ell} \) have:

\[
\ell \circ \varphi \quad \text{which proves (2). The last item follows directly from M.T.}
\]

The first part follows from a direct computation:

\[
\ell_{M.T}(X/T^\perp) = \ell_{M/T^\perp}(X/T^\perp) = \ell(X).
\]

**Lemma 26.** Let \( T \leq E \) and \( M = (E, \rho) \) a q-polymatroid. The following hold.

1. \( \ell_{M,T}(X/T^\perp) = \ell_{M/T^\perp}(X/T^\perp) = \ell(X). \)
2. \( p(M,T;z) = \sum_{T^\perp \leq X \leq E} \mu(T^\perp, X)z^{\ell(X)}. \)
3. \( p(M/T;z) = \sum_{T \leq X \leq E} \mu(T, X)z^{\ell(X)}. \)

**Proof.** The first part follows from a direct computation:

\[
\ell_{M,T}(X/T^\perp) = \ell_{M/T^\perp}(X/T^\perp) = \rho_{M/T^\perp}(E/T^\perp) - \rho_{M/T^\perp}(X/T^\perp)
\]

\[
= \rho(E) - \rho(T^\perp) - \rho(X) + \rho(T^\perp)
\]

\[
= \rho(E) - \rho(X) = \ell(X).
\]

Let \( \bar{\mu} \) denote the M"obius function on the lattice of subspaces of \( E/T \). Then, applying (1) we have:

\[
p(M,T;z) = p(M/T^\perp;z) = \sum_{T^\perp \leq X \leq E} \bar{\mu}(0, X/T^\perp)z^{\ell_{M/T^\perp}(X/T^\perp)} = \sum_{T^\perp \leq X \leq E} \mu(T^\perp, X)z^{\ell(X)},
\]

which proves (2). The last item follows directly from \( M.T = M/T^\perp \) (Definition 10). \( \square \)

Clearly, if \( T \) has dimension \( t \), then \( p(M,T;z) = \sum_{j=0}^{t} (-1)^j q^{(j)} \sum_{T^\perp \leq Y, \dim(Y) = n-t+j} z^{\ell(Y)}. \)

**Example 27.** We calculate \( p(M,T;z) \) where \( M \) is the Vamos q-matroid (Example 17). Let \( T \) be a subspace of \( E = \mathbb{F}_q^8 \). If \( T \) has dimension 5, then \( \dim T^\perp = 3 \). We need only consider two cases, depending on whether or not \( T^\perp \) is contained in a circuit (a member of \( C \)). Note that the circuits intersect pairwise in dimension 2 or 0, so \( T^\perp \) cannot be in more than one circuit.

Suppose \( T^\perp \) is in none of the circuits. Then for all \( X \) such that \( T^\perp < X \leq E \) we have that \( \ell(X) = 0 \). For \( X = T^\perp \), we have \( \ell(X) = 1 \). So the q-matroid \( M.T \) is lattice-equivalent to the uniform q-matroid \( U_{1,5} \). Its characteristic polynomial is

\[
p(M,T;z) = \mu(T^\perp, T^\perp)z^1 + \sum_{T^\perp < X \leq E} \mu(T^\perp, X)z^0 = z - 1.
\]

Suppose now that \( T^\perp \) is contained in a circuit \( C \in C \). Among all \( X \) such that \( T^\perp \leq X \leq E \) we have that \( \ell(X) = 1 \) for \( X = T^\perp \) and \( X = C \). Otherwise, \( \ell(X) = 0 \). The q-matroid \( M.T \) has rank 1 and all 1-dimensional spaces are independent, except for the circuit \( C/T^\perp \). For the
characteristic polynomial we get the following:

\[
p(M.T; z) = \mu(T^\perp, T^\perp) z + \mu(T^\perp, C) z + \sum_{X : T^\perp < X \leq E, X \neq C} \mu(T^\perp, X)
\]

\[
= z - z - \left(\frac{8 - 3}{4 - 3} - 1\right) + q \left[\frac{8 - 3}{5 - 3}\right] - q^3 \left[\frac{8 - 3}{6 - 3}\right] + q^6 \left[\frac{8 - 3}{7 - 3}\right] - q^{10},
\]

\[
= - \left(\frac{5}{1} - 1\right) + q \left[\frac{5}{2}\right] - q^3 \left[\frac{5}{3}\right] + q^6 \left[\frac{5}{4}\right] - q^{10} = 0.
\]

In fact, since \( \sum_{X : T^\perp < X \leq E, X \neq C} \mu(T^\perp, X) + 1 + \mu(T^\perp, C) = 0 \), we see that the constant term is zero without the need for any calculation.

We continue to develop technical properties of the characteristic polynomial of the contraction \( M.T \). In Section 6, we will use the fact that the characteristic polynomial of \( M.T \) is identically zero when \( T \) is an independent space of the dual \( q \)-polymatroid.

**Lemma 28.** \( T \leq E \) is an independent space of \( M^* \) if and only if \( \ell(T^\perp) = 0 \).

**Proof.** We have

\[
\ell(T^\perp) = \rho(E) - \rho(T^\perp) = \rho(E) - (\rho^*(T) + \rho(E) - r \dim T) = r \dim(T) - \rho^*(T).
\]

Hence \( T \) is an independent space of \( M^* \) if and only if \( \ell(T^\perp) = 0 \). \( \square \)

**Lemma 29.** If \( T \leq E, \dim T > 0 \) is an independent space of \( M^* \), then \( p(M.T; z) = 0 \).

**Proof.** By Lemma 28, \( \ell(T^\perp) = 0 \). Since all subspaces of an independent space are independent, we have that \( \ell(X) = 0 \) for all \( T \) such that \( T^\perp \leq X \). Applying this to the characteristic polynomial, we get

\[
p(M.T; z) = \sum_{T^\perp \leq X \leq E} \mu(T^\perp, X) z^{\ell(X)} = \sum_{T^\perp \leq X \leq E} \mu(T^\perp, X) = 0.
\]

\( \square \)

**Lemma 30.** Let \( T \leq E \) be a circuit of \( M^* = (E, \rho^*) \). Then \( p(M.T; z) = z^{\ell(T^\perp)} - 1 \).

**Proof.** Let \( X \leq E \). If \( T^\perp \) is strictly contained in \( X \), then \( T^\perp \) is strictly contained in \( X^\perp \), and so \( X^\perp \) is independent in \( M^* \). Therefore, Lemma 28 gives that \( \ell(X) = 0 \). Hence

\[
p(M.T; z) = \sum_{T^\perp \leq X \leq E} \mu(T^\perp, X) z^{\ell(X)} = z^{\ell(T^\perp)} + \sum_{T^\perp < X \leq E} \mu(T^\perp, X)
\]

\[
= z^{\ell(T^\perp)} - \mu(T^\perp, T^\perp) = z^{\ell(T^\perp)} - 1.
\]

\( \square \)

**Remark 31.** Note that if \( M \) is a \( q \)-matroid, a cocircuit \( T \) of \( M \) has \( \ell(T^\perp) = \dim(T) - \rho^*(T) = \dim(T) - (\dim(T) - 1) = 1 \) hence \( p(M.T; z) = z - 1 \).

**Lemma 32.** Let \( M = (E, \rho) \) be a \( q \)-polymatroid and let \( T \leq E \) be an independent space of \( M^* \). The following hold.

1. \( \rho(E) = \rho(T^\perp) \).
2. For any subspace \( U \leq T^\perp \), we have \( \ell_M|_{T^\perp}(U) = \ell(U) \).

**Proof.** By definition of the dual \( q \)-polymatroid, we have \( \rho(T^\perp) = \rho^*(T) - r \dim(T) + \rho(E) \). Since \( T \) is independent in \( M^* \), \( \rho^*(T) = r \dim(T) \) and so we get \( \rho(T^\perp) = \rho(E) \), which establishes (1). Therefore, \( \ell_M|_{T^\perp}(U) = \rho_M|_{T^\perp}(T^\perp) - \rho_M|_{T^\perp}(U) = \rho(T^\perp) - \rho(U) = \rho(E) - \rho(U) = \ell(U) \), which proves (2). \( \square \)

**Corollary 33.** Let \( T \leq U \) be subspaces of \( E \) such that \( T \) is independent in \( M^* \). If \( U/T \) is a circuit in \( M^*/T \), then

\[
p((M^*/T)^*, (U/T); z) = p(M|_{T^\perp}, (U^\perp)^\perp(T^\perp); z) = z^{\ell(U^\perp)} - 1.
\]
Proof. Recall from Lemma 11 that \( M^*/T \cong (M|T^\perp)^* \) (and hence \((M^*/T)^* \cong M|T^\perp\) under the map \( \phi : A/T \to (A^\perp)^\perp(T^\perp) \) for any \( A \leq E \) with \( T \leq A \). In particular, if \( U/T \) is a circuit in \( M^*/T \), then \( \phi(U/T) \) is a circuit in \((M|T^\perp)^*\). Moreover \( \phi(U/T)^\perp(T^\perp) = U^\perp \). From Lemmas 32 and 30 we have
\[
p((M^*/T)^*(U/T); z) = p(M|T^\perp; \phi(U/T); z) = z^\ell_{M|T^\perp(U^\perp)} - 1 = z^\ell(U^\perp) - 1.
\]
\(\square\)

The following result will be used in the proof of Corollary 69.

**Lemma 34.** Let \( W \leq E \) and let \( T \leq W \) be an independent space of \( M^* \). Then
\[
p(M|T^\perp/W^\perp; z) = \sum_{A: A+T=W} p(M|A; z).
\]

**Proof.** By Lemmas 26 and 32, we have \( \ell_{M|T^\perp/W^\perp}(U/W^\perp) = \ell(U) \) for any subspace \( U \) satisfying \( T \leq U^\perp \leq W \). Since \( p(M/U; z) = \sum_{A: U \leq A \leq E} \mu(U, A) \ell(A) \), by applying the Möbius inversion formula we have \( z^{\ell(U)} = \sum_{A: U \leq A \leq E} p(M|A; z) \). Therefore, we have
\[
p(M|T^\perp/W^\perp; z) = \sum_{U: W^\perp \leq U \leq T^\perp} \mu(W^\perp, U) \ell(U) \sum_{A: U \leq A \leq E} \mu(U, A) \ell(A) \sum_{A: A \leq A \leq E} p(M|A; z)
\]
\[
= \sum_{U: W^\perp \leq U \leq T^\perp} \mu(W^\perp, U) \sum_{A: U \leq A \leq E} \mu(U, A) \ell(A) \sum_{A: A \leq A \leq E} p(M|A; z)
\]
\[
= \sum_{V: W^\perp \leq V \leq T^\perp} \mu(W^\perp, V^\perp) \sum_{A: V^\perp \leq A \leq E} \mu(V^\perp, A) \ell(A) \sum_{A: A \leq A \leq E} p(M|A; z)
\]
\[
= \sum_{A: 0 \leq A \leq W} \mu(M|A; z) \sum_{V: A+T \leq V \leq W} \mu(W^\perp, V^\perp)
\]
\[
= \sum_{A: A+T=W} p(M|A; z),
\]
where the last equality follows from the fact that
\[
\sum_{V: A+T \leq V \leq W} \mu(W^\perp, V^\perp) = \begin{cases} 1 & \text{if } A^\perp \cap T^\perp = W^\perp, \\ 0 & \text{otherwise}. \end{cases}
\]
\(\square\)

We now present some further results on the characteristic polynomial.

**Definition 35.** A *loop* of the \((q, r)\)-polymatroid \( M \) is a circuit of dimension 1.

Clearly, if \( e \) is a loop of \( M \), then \( 0 \leq \rho(e) < r \). If \( M \) is a \( q \)-matroid, then the loops of \( M \) all have rank zero.

**Lemma 36.** Let \( e \) be a one-dimensional subspace of \( E \). The following are equivalent:

1. \( p(M; e; z) = 0 \),
2. \( \rho(e^\perp) = \rho(E) \),
3. \( e \) is not a loop in \( M^* \).

**Proof.** We have \( p(M; e; z) = z^{\ell(e^\perp)} - z^{\ell(E)} = z^{\ell(e^\perp)} - 1 \), which is zero if and only if \( \ell(e^\perp) = \rho(E) - \rho(e^\perp) = 0 \). This shows that (1) and (2) are equivalent. The one-dimensional space \( e \) is independent in \( M^* \) if and only if \( \rho^*(e) = r \). Since \( \rho^*(e) = r \dim(e) - \rho(E) + \rho(e^\perp) =
\[ r - \rho(E) + \rho(e^\perp), \] this occurs if and only if \( \rho(e^\perp) = \rho(E) \), which shows that (2) and (3) are equivalent. 

**Remark 37.** We remark that for a classical matroid \( M \), if \( e \) is a loop of \( M \), then it is easy to see that \( p(M.e; z) = 0 \). This is because if \( e \) is a loop, by semimodularity, the fact that \( e \notin E - e \) forces \( \rho(E - e) = \rho(E) \). Then by the classical version of the lemma above, this gives that \( p(M.e; z) = 0 \). For a \( q \)-matroid, however, it may occur that \( e \leq e^\perp \), in which case if \( e \) is a loop, the same argument using semimodularity does not imply that \( \rho(e^\perp) = \rho(E) \).

**Definition 38.** For each \( A \in \mathcal{L}(E) \), define \( c(A) := \{ X \leq E : A \leq X, \rho(A) = \rho(X) \} \). The closure of \( A \) in the \((q, r)\)-polymatroid \( M \) is denoted by \( \text{cl}(A) \) and is defined to be the vector space sum of the members of \( c(A) \); that is, \( \text{cl}(A) := \sum_{X \in c(A)} X \).

**Lemma 39.** Let \( L = \text{cl}([0]) \). Let \( X \) be a subspace of \( E \) such that \( X^\perp \leq L \). Then

\[
p(M.X; z) = \begin{cases} z^{\rho(E)} + \sum_{A: X^\perp \leq A \leq E} \mu(X^\perp, A)z^{\ell(A)} & \text{if } X = L^\perp, \\ \sum_{A: X^\perp \leq A \leq E, A \notin L} \mu(X^\perp, A)z^{\ell(A)} & \text{otherwise.} \end{cases}
\]

If \( X^\perp = L \), then \( p(M.X; z) \) is a monic polynomial of degree \( \rho(E) \) in \( z \). In particular, if \( M \) is a \( q \)-matroid and has no loops, then \( p(M.z; z) \) is monic polynomial of degree \( \rho(E) \).

**Proof.** From Lemma 26 we have that

\[
p(M.X; z) = \sum_{A: X^\perp \leq A \leq E} \mu(X^\perp, A)z^{\ell(A)} = z^{\rho(E)} \sum_{A: X^\perp \leq A \leq L} \mu(X^\perp, A) + \sum_{A: X^\perp \leq A \leq E, A \notin L} \mu(X^\perp, A)z^{\ell(A)}.
\]

By the definition of the Möbius function, \( \sum_{A: X^\perp \leq A \leq L} \mu(X^\perp, A) = 0 \) unless \( X^\perp = L \). If \( A \notin L \), then \( \ell(A) = \rho(E) - \rho(A) < \rho(E) \), so if \( L = X^\perp \), then \( p(M.X; z) \) is a monic polynomial with leading term \( z^{\rho(E)} \). Furthermore, setting \( X = E \), we obtain that if \( M \) is a \( q \)-matroid with no loops, then its characteristic polynomial is monic of degree \( \rho(E) \).

**Remark 40.** If \( M \) is a \( q \)-matroid, \( \text{cl}(\{0\}) \) is the space containing all the loops.

In the \( q \)-matroid case, cryptomorphisms between axiom systems such as those relating to independent spaces, the closure function, flats, hyperplanes etc., were established in [9]. We therefore have the following facts, as in the case for classical matroids. The reader is referred to [9] and the references therein for further details. A subspace \( F \) is called a flat of a \( q \)-matroid if \( \text{cl}(F) = F \). For each \( B \leq E \), there is a unique flat \( F \) such that \( \text{cl}(B) = F \), in which case \( \rho(B) = \rho(F) \). Moreover, if \( M \) is a \( q \)-matroid, its collection of flats forms a semi-modular lattice [8]. A hyperplane \( H < E \) is a flat that is maximal with respect to containment, that is, if \( H \leq F \) for some flat \( F \), then either \( F = E \) or \( F = H \). Every flat of \( M \) is an intersection of hyperplanes and for every hyperplane \( H \), we have that \( H^\perp \) is a cocircuit of \( M \). Therefore, for every flat \( F \) of \( M \), \( F^\perp \) is the vector space sum of a collection of cocircuits.

The following result will be used in Corollary 74.

**Theorem 41.** Let \( M \) be a \( q \)-matroid. Let \( X \leq E \) contain a unique cocircuit \( C \). Then

\[
p(M.X; z) = \begin{cases} z - 1 & \text{if } X = C, \\ 0 & \text{otherwise.} \end{cases}
\]

**Proof.** If \( X = C \), then by Remark 31 we have that \( p(M.X; z) = z - 1 \). Assume now that \( C \leq X \). Then \( X \) is not a sum of cocircuits of \( M \) and hence \( X^\perp \) is not a flat. Clearly \( X \) is a dependent space of \( M^* \) and by the uniqueness of \( C \), any subspace of \( X \) that is dependent in \( M^* \) contains \( C \). Therefore, by Lemma 28, \( \ell(A^\perp) = 0 \) for every \( A \leq X \) such that \( C \notin A \).
Let $F$ be a flat of $M$. For any $A \leq E$ such that $\text{cl}(A^\perp) = F$, we have $\rho(A^\perp) = \rho(F)$ and hence $\ell(A^\perp) = \ell(F)$. Furthermore, $\text{cl}(C^\perp) = C^\perp$ since $C$ is a cocircuit of $M$. This will be used in the following computation of $p(M.X; z)$:

$$p(M.X; z) = \sum_{A: X^\perp \leq A \leq E} \mu(X^\perp, A)z^{\ell(A)} = \sum_{A: X \leq A} \mu(A, X)z^{\ell(A^\perp)}$$

$$= \sum_{A: C \leq A \leq X} \mu(A, X)z^{\ell(A^\perp)} + \sum_{A: A \leq X, C \not\leq A} \mu(A, X)$$

$$= \sum_{F: \text{cl}(F) = F} \sum_{A: X^\perp \leq A^\perp \leq C^\perp} \mu(X^\perp, A^\perp)z^{\ell(F)} + \sum_{A: A \leq X} \mu(A, X) - \sum_{A: C \leq A \leq X} \mu(A, X)$$

$$= \sum_{F: \text{cl}(F) = F} \sum_{A: X^\perp \leq A^\perp \leq C^\perp \leq \text{cl}(A^\perp) = F} \mu(X^\perp, A^\perp).$$

Since the lattice of flats of $M$ is semi-modular, by [33, Proposition 3.3], we have

$$\sum_{A: X^\perp \leq A^\perp \leq C^\perp, \text{cl}(A^\perp) = F} \mu(X^\perp, A^\perp) = 0,$$

and so the result follows. \hfill \square

Remark 42. In fact, by a similar argument (also essentially the same as for classical matroids), for a $q$-matroid $M$, we have $p(M.X; z) = 0$ unless $X^\perp$ is a flat in $M$. Equivalently, we have that $p(M.X; z) = 0$ unless $X$ is a sum of cocircuits of $M$.

3.3. The Weight Enumerator of a $q$-Polymatroid. We next define the weight enumerator of a $q$-polymatroid. In Section 5, we will show that its values satisfy a duality property and in Section 6, we will apply this duality result to establish a criterion for identifying a weighted subspace design determined by a $q$-polymatroid.

Definition 43. We define the weight enumerator of the $(q, r)$-polymatroid $M$ to be the list $[A_M(i; z) : 0 \leq i \leq n]$, where for each $i$ we define

$$A_M(i; z) := \sum_{X \leq E, \dim(X) = i} p(M.X; z) = \sum_{X \leq E, \dim(X) = i} p(M/X^\perp; z).$$

Lemma 44. Let $T \leq E$. The following hold.

1. If $T \leq Z \leq E$, then $p((M/T)/(Z/T); z) = p(M.Z^\perp; z)$.
2. $A_M(T; z) = \sum_{X \leq T^\perp, \dim(X) = j} p(M.X; z)$.

Proof. Let $T \leq Z \leq Y \leq E$. Then $(Y/T)/(Z/T)$ and $Y/Z$ are isomorphic. Let $V = (E/T)/(Z/T)$ and write $M_V = (M/T)/(Z/T)$. We have a lattice isomorphism between $\mathcal{L}(E/Z)$ and $\mathcal{L}(V)$. Moreover, it is easy to check that $\rho_{M_V}((Y/T)/(Z/T)) = \rho_{M/Z}(Y/Z)$. Therefore, $M_V$ and $M/Z$ are lattice-equivalent $q$-polymatroids. We thus have $p(M_V; z) = p(M/Z; z) = p(M.Z^\perp; z)$.

Let $X \leq T^\perp$. It is straightforward to check that $\dim((X^\perp/T^\perp)(E/T)) = \dim(X)$. Therefore,

$$A_M(T; z) = \sum_{X: X^\perp \leq E, \dim((X^\perp/T^\perp)(E/T)) = j} p((M/T)/(X^\perp/T^\perp); z) = \sum_{X: X \leq T^\perp} p(M.X; z).$$
4. Matrix Codes and $q$-Polymatroids

We consider properties of a $q$-polymatroid arising from an $\mathbb{F}_q$-linear rank-metric code. There are several papers outlining properties of rank-metric codes. The $q$-polymatroids associated with these structures have been studied in [18, 19, 29].

**Notation 45.** Throughout this section, we let $m$ be a positive integer and $E = \mathbb{F}_q^n$. We write $U^\perp$ to denote the orthogonal complement of $U \leq E$ with respect to a non-degenerate symmetric bilinear form $b_E$ on $E$. By abuse of notation, we also write $U^\perp$ to denote the orthogonal complement of

- $U \leq \mathbb{F}_q^{n \times m}$ with respect to the inner product $b_{\mathbb{F}_q^{n \times m}}$ defined by $b_{\mathbb{F}_q^{n \times m}}(X,Y) = Tr(XY^T)$ for all $X,Y \in \mathbb{F}_q^{n \times m}$ and
- $U \leq \mathbb{F}_q^n$, with respect to the dot product defined by $x \cdot y = \sum_{i=1}^n x_i y_i$ for all $x = (x_1, \ldots, x_n), y = (y_1, \ldots, y_n) \in \mathbb{F}_q^n$.

**Definition 46.** We say that $C \subseteq \mathbb{F}_q^{n \times m}$ is a linear rank-metric code, or a matrix code if $C$ is a subspace of $\mathbb{F}_q^{n \times m}$. The **minimum distance** of $C$ is the minimum rank of any nonzero member of $C$. We say that $C$ is an $\mathbb{F}_q^n[n \times m, k, d]$ rank-metric code if it has $\mathbb{F}_q$-dimension $k$ and minimum distance $d$. The **dual code** of $C$ is $C^\perp := \{ Y \in \mathbb{F}_q^{n \times m} : Tr(XY^T) = 0 \ \forall X \in C \}$. Finally, for each $i \in \{0, \ldots, n\}$, we define $W_i(C) := \{ (A \in C : \text{rank}(A) = i) \}$. The list $[W_i(C) : 0 \leq i \leq n]$ is called the **weight distribution** of $C$.

For $X \leq \mathbb{F}_q$ we write $\text{colsp}(X)$ to denote the column space of $X$ over $\mathbb{F}_q$.

**Definition 47.** Let $X \in \mathbb{F}_q^{n \times m}$ and let $U \leq E$. We say that $U$ is the support of $X$ if $\text{colsp}(X) = U$. Let $C$ be an $\mathbb{F}_q^n[n \times m, k, d]$ rank-metric code. We say that $U$ is a **support** of $C$ if there exists some $X \in C$ with support $U$.

**Definition 48.** Let $m$ be a positive integer and let $C$ be an $\mathbb{F}_q^n[n \times m, k, d]$ rank-metric code. For each subspace $U \leq E$, we define

$$C_U := \{ A \in C : \text{colsp}(A) \leq U^\perp \} \quad \text{and} \quad C_{=U} := \{ A \in C : \text{colsp}(A) = U^\perp \}.$$ 

Let $\rho : \mathcal{L}(E) \to \mathbb{N}_{\geq 0}$ be defined by $\rho(U) := k - \text{dim}(C_U)$. Then $(E, \rho)$ is a $(q,m)$-polymatroid [19, Theorem 5.3] and we denote it by $M_C$.

Clearly, we have $\ell(U) = \text{dim}(C_U)$ for every $U \leq E$.

**Lemma 49.** Let $C$ be an $\mathbb{F}_q^n[n \times m, k, d]$ rank-metric code. The following hold.

1. $M_{C^\perp} = (M_C)^*$.
2. $p(M_C/U; q) = |C_{=U}|$.
3. $W_i(C) = A_{M_C}(i; q)$ for each $i \in \{1, \ldots, n\}$.
4. $A_{M_C}(i; q) = 0$ if and only if $p(M_C/U; q) = 0$ for every $i$-dimensional subspace $U \leq E$.
5. If $A_{M_C}(i; q) = 0$, then $A_{M_C/T}(i; q) = 0$ for every subspace $T \leq E$.

**Proof.** (1) has been established in [19, Theorem 7.1]. Let $M = M_C$. Since $|C_U| = \sum_{V : U \leq V} |C_{=V}|$, by Möbius inversion we have

$$|C_{=U}| = \sum_{V : U \leq V} \mu(U,V)|C_V| = \sum_{V : U \leq V} \mu(U,V)q^{\ell(V)} = p(M.U^\perp; q) = p(M/U; q).$$

Therefore (2) holds. The number of codewords of $C$ that have rank $i$ over $\mathbb{F}_q$ is

$$W_i(C) = \sum_{U : \text{dim}(U) = n - i} |C_{=U}| = \sum_{U : \text{dim}(U) = n - i} p(M.U^\perp; q) = \sum_{U : \text{dim}(U) = i} p(M.U; q) = A_M(i; q),$$

which gives (3). Clearly, $A_M(i; q) = 0$ if and only if $p(M.U; q) = 0$ for each $U \leq E$ of dimension $i$, which gives (4). Let $T$ be a subspace of $E$. By Lemma 44 we have

$$A_{M/T}(i; q) = \sum_{X \leq T^\perp : \text{dim}(X) = i} p(M.X; q).$$
If \( A_M(i; q) = 0 \), then from (4) we have \( p(M.X; q) = 0 \) for each \( i \)-dimensional subspace \( X \), and so we get \( A_M/T(i; q) = 0 \), which proves (5). \( \square \)

**Remark 50.** Note that Part (2) of Lemma 49 is an instance of the Critical Theorem [14] for \( q \)-polymatroids and matrix codes.

**Remark 51.** In [19], the authors define a pair of \( q \)-polymatroids associated with a matrix code. The one given above is the \( q \)-polymatroid whose rank function is determined by the column-spaces of the codewords. A second \( q \)-polymatroid is the one whose rank function is determined by the row spaces of the codewords.

One way to construct an \( F_q[n \times m, k, d] \) rank-metric code is by taking a subspace of \( F_q^n \), and expanding its elements with respect to a basis of \( F_q^n \) over \( F_q \). Such rank-metric codes are referred to as vector rank-metric codes.

**Definition 52.** Let \( \Gamma \) be a basis of \( F_q^n \) over \( F_q \). For each \( x \in F_q^n \), we write \( \Gamma(x) \) to denote the \( n \times m \) matrix over \( F_q \) whose \( i \)th row is the coordinate vector of the \( i \)th coefficient of \( x \) with respect to the basis \( \Gamma \). The rank of \( x \) is the rank of the matrix \( \Gamma(x) \). Note that the rank of \( x \) is well-defined, being independent of the choice of basis \( \Gamma \).

For the remainder, we fix \( \Gamma \) to be a basis of \( F_q^n \) over \( F_q \).

**Definition 53.** A (linear rank-metric) vector code \( C \) is an \( F_q^n \)-subspace of \( F_q^m \). The minimum distance of \( C \) is the minimum rank of any non-zero element of \( C \). We say that \( C \) is an \( F_q^n \)[\( n, k, d] \) code if it has \( F_q^n \)-dimension \( k \) and \( \Gamma(C) \) has minimum rank distance \( d \). The code \( C^\perp \) denotes the dual code of \( C \) with respect to the standard dot product on \( F_q^n \).

Each vector rank-metric code determines a \( q \)-matroid, as follows.

**Definition 54.** Let \( C \) be an \( F_q^n-[n, k, d] \) rank-metric code. Let \( U \leq E \) and let \( x \in C \). We say that \( U \) is a support of \( x \) if \( U \) is the column space of \( \Gamma(x) \) and we write \( \sigma(x) = U \). For each subspace \( U \leq E \), we define \( C_U := \{ x \in C : \sigma(x) \leq U^\perp \} \) and \( C_{=U} := \{ x \in C : \sigma(x) = U^\perp \} \).

Let \( \rho : \mathcal{L}(E) \rightarrow \mathbb{N}_{\geq 0} \) be defined by \( p(U) := k - \dim_{F_q}(C_U) \). Then \( (E, \rho) \) is a \( q \)-matroid [20, Theorem 24] and we denote it by \( M_C \).

**Remark 55.** Note that in the definition given above, the rank function for the \( q \)-matroid of \( C \) is the rank function of the associated \( (q, m) \)-polymatroid as defined in Definition 48, divided by \( m \). Since \( C \) is \( F_q^n \)-linear, \( C_U \) is an \( F_q^n \)-vector space for each subspace \( U \) and so has \( F_q^n \)-dimension a multiple of \( m \). Therefore the results of Lemma 49 hold with \( q^m \) in place of \( q \). For example, with respect to the characteristic polynomial of the \( q \)-matroid, we have \( p(M/U; q^m) = |C_{=U}| \) for an \( F_q^n-[n, k, d] \) code \( C \) and subspace \( U \).

Let \( C \) be an \( F_q^n-[n, k, d] \) code. Recall that for any \( U \leq F_q^n \) we have \( \ell_{MC}(U) = \dim_{F_q}(C_U) = \dim(\{ x \in C : \sigma(x) \leq U^\perp \}) \).

Now \( U^\perp \) is independent in \( M_C^\perp \) if and only if \( \ell_{MC}(U) = 0 \), which occurs if and only if no subspace of \( U^\perp \) is a support of \( C \). Therefore every support of \( C \) corresponds to a dependent space of \( M_C^\perp \).

In the following example we illustrate the notions discussed in Sections 3 and 4. We calculate the characteristic polynomial of \( M_C \) by carefully studying the structure of the \( q \)-matroid and its dual.

**Example 56.** Let \( \alpha \) be a root of \( x^6 + x^4 + x^3 + x + 1 \in F_{26}[x] \). Then \( \alpha \) is a primitive element of \( F_{26} \). Let \( C \) be the \( F_{26}-[6, 3, 3] \) vector rank-metric code generated by the matrix:

\[
G = \begin{bmatrix}
1 & 0 & 0 & \alpha^{13} & \alpha^{47} & \alpha^{35} \\
0 & 1 & 0 & \alpha^{14} & \alpha^{62} & \alpha^{32} \\
0 & 0 & 1 & \alpha^{34} & \alpha^{22} & \alpha^{19}
\end{bmatrix}
\]
With respect to the basis \( \Gamma = \{1, \ldots, \alpha^5\} \), the rows of \( G \) are expanded to the following binary matrices:

\[
\begin{bmatrix}
1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 1 & 0 & 0 \\
0 & 1 & 0 & 1 & 1 & 1 \\
1 & 0 & 0 & 0 & 1 & 0
\end{bmatrix}
\begin{bmatrix}
0 & 0 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 1 & 1 & 1 \\
1 & 0 & 1 & 1 & 0 & 1 \\
0 & 1 & 1 & 1 & 0 & 1
\end{bmatrix}
\begin{bmatrix}
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 & 0 & 0 \\
1 & 0 & 1 & 1 & 0 & 1 \\
0 & 0 & 1 & 1 & 1 & 0 \\
0 & 1 & 1 & 1 & 0 & 1
\end{bmatrix}
\]

A basis of \( \Gamma(C) \) over \( \mathbb{F}_2 \), which has 18 elements, is found by multiplying each row of \( G \) by successive powers of \( \alpha \) and expanding with respect to \( \Gamma \). We have that \( \Gamma(C) \) is an \( \mathbb{F}_2[6 \times 6, 18, 3] \) rank-metric code with rank-metric weight distribution \([1, 0, 0, 567, 37044, 142884, 81648]\). Moreover, \( C \) is formally self-dual, that is, its dual code has the same weight distribution as \( C \). Now consider the \( q \)-matroid \( M := M_C \) arising from \( C \), with rank function satisfying \( \rho(U) = 3 - \dim_{\mathbb{F}_2} (C_U) \) for each \( U \leq \mathbb{F}_2^6 \). In Figure 1 we write down the number of subspaces of \( \mathbb{F}_2^6 \) for each possible value of \( \ell(U) = \dim_{\mathbb{F}_2} (C_U) \).

| \( \ell(U) \) | \( \dim(U) \) | 0 | 1 | 2 | 3 | 4 | 5 | 6 |
|----------------|-------------|---|---|---|---|---|---|---|
| 0              | 0           | 0 | 0 | 0 | 6 | 4 | 6 | 5 |
| 1              | 0           | 0 | 0 | 6 | 2 | 9 | 0 | 0 |
| 2              | 0           | 6 | 0 | 0 | 0 | 0 | 0 | 0 |
| 3              | 1           | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**Figure 1.** Number of subspaces for each possible \( \ell(U) \) value.

Using the entries of the table of Figure 1, we write down the characteristic polynomial of \( M \):

\[
p(M; z) = \sum_{U : 0 \leq U \leq E} \mu(0, U) z^{\ell(U)}
\]

\[
= z^3 + \sum_{U : 0 \leq U \leq E, \ell(U) = 2} \mu(0, U) z^2 + \sum_{U : 0 \leq U \leq E, \ell(U) = 1} \mu(0, U) z + \sum_{U : 0 \leq U \leq E, \ell(U) = 0} \mu(0, U)
\]

\[
= z^3 - 63z^2 + 1230z - 1168 = (z-1)(z^2 - 62z + 1168).
\]

We will explain the values in this table column by column from right to left: recall that to say something about \( \ell(U) \), we have to consider how the supports of \( C \) relate to \( U^\perp \). Along the way, we will compute the different possible values of \( p(M/U; q^m) = |C_{=U}| \), which, by Lemma 49, counts the number of codewords of \( C \) with support equal to \( U^\perp \).

Since the rank distance of \( C \) is 3, \( C \) has no supports of dimension less than 3 apart from \( \{0\} \). Hence \( \ell(U) = \dim_{\mathbb{F}_2} (C_U) = 0 \) for each of the 651 subspaces \( U \leq \mathbb{F}_2^6 \) of dimension 4 and each of the 63 spaces of dimension 5. So by Lemma 28, the respective 1 and 2-dimensional orthogonal complements of these spaces are independent in \( M^* \). We remark that by Lemma 49, we have \( M^* = M_{C^\perp} \).

We now consider the 3-dimensional subspaces. Since any proper subspace of a 3-dimensional subspace \( U \leq \mathbb{F}_2^6 \) is independent in \( M^* \), it must be the case that if \( U \) is dependent in \( M^* \), it is a cocircuit of \( M \). Then by Remark 31, we have \( \ell(U^\perp) = 1 \) (indeed \( p(M.U; z) = z - 1 \)) and \( p(M.U; 2^6) = |C_{=U^\perp}| = 2^6 - 1 = 63 \). Therefore, by inspection of the weight enumerator, we see that there are \( 9 = 567/63 \), different 3-dimensional spaces that are supports of \( C \). We list the
3-dimensional cocircuits of $M$ below:

\[
\{(010011), (001010), (000100), (101100), (010000), (000001), (010001), (011000), (000010),
(001011), (000111), (010101), (010100), (010110), (000111), (011001), (001011), (000011),
(100000), (010110), (001000)\}.
\]

Every other 3-dimensional subspace $U$ is a non-support of $C$, as are all its nontrivial subspaces, hence $\ell(U^\perp) = \dim_{\mathbb{F}_2}(C_{U^\perp}) = 0$. We remark that Lemma 28 says for such $U$ that $U^\perp$ is independent in $M^*$, and Lemma 29 gives that $p(M.U; z) = 0$. By computation, we obtain that there are 588 4-dimensional supports of $C$ and that none of these spaces contains a cocircuit of dimension 3. Therefore, each such subspace $U$ is itself a cocircuit and so we have that $\ell(U^\perp) = 1$,

\[
p(M.U; z) = z - 1, \quad \text{and} \quad p(M.U; 2^6) = |C_{U^\perp}| = 2^6 - 1.\]

There remain a further $\frac{6}{4} - 588 = 63$ 4-dimensional subspaces that are not supports of $C$. Every 3-dimensional cocircuit is contained in $\binom{6}{4} - 3 = 7$ different 4-dimensional spaces and every pair of 3-dimensional cocircuits shares $\binom{2}{1} = 2$ spans $\mathbb{F}_2^6$. Therefore, every 4-dimensional non-support of $C$ contains at most one 3-dimensional cocircuit and since there are $9 \cdot 7 = 63$ such 4-dimensional non-supports altogether, each of them contains a unique 3-dimensional cocircuit. It follows that $\ell(U^\perp) = 1$ for every 4-dimensional subspace $U$.

By direct computation it can be checked that there are 63 5-dimensional supports of $C$ and of course the only 6-dimensional support is the entire space $\mathbb{F}_2^6$. Each 5-dimensional support $U$ is the support of exactly 2268 different codewords, so $p(M.U; 2^6) = |C_{U^\perp}| = 2268$. Therefore, $\ell(U^\perp) = \dim_{\mathbb{F}_2}(C_{U^\perp}) \geq 2$. If $\ell(U^\perp) = 3$ then the support of every codeword is contained in $U$, which is impossible as $C$ has words of rank 6. It follows that $\ell(U^\perp) = 2$. All computations carried out in this example were done using MAGMA [3].

5. MACWILLIAMS IDENTITIES FOR $q$-POLYMATROIDS

We establish a version of the MacWilliams identities for the $(q, r)$-polymatroids that we shall use in establishing criteria for the existence of a weighted $t$-design over $\mathbb{F}_q$. Duality via the rank polynomial of a $q$-polymatroid was considered in [29]. We start with a result that relates the characteristic polynomial of a $q$-polymatroid to that of its dual. The statements of Theorem 57 and Corollary 58 may be regarded as $q$-analogues of [6, Corollary 12]. However, unlike the proofs given here, which rely only on Möbius inversion, the proof of [6, Corollary 12] relies on an existing version of MacWilliams duality theorem for matroids, which shows that the weight enumerator polynomial of the dual of a matroid can be retrieved from the weight enumerator polynomial of the original matroid by a substitution of variables. A $q$-analogue of this result is not known.

**Theorem 57.** Let $U \leq E$. Then

\[
\sum_{A: A \leq U} p(M^*.A; z) = z^{r \dim(U) - \rho(E)} \sum_{A: A \leq U^\perp} p(M.A; z).
\]

**Proof.** We have by Lemma 26 and then replacing $X$ with $A^\perp$ that

\[
p(M^*.U; z) = \sum_{X: U^\perp \leq X \leq E} \mu(U^\perp, X) z^{r^*(X)} = \sum_{A: A \leq U} \mu(A, U) z^{r^*(A^\perp)}.
\]

16
To this we apply Möbius inversion (Lemma 18 part (2)), duality (Definitions 6 and 21) and Möbius inversion again to get

\[ \sum_{A : U \leq A \leq E} p(M^*A; z) = z^{\ell(U)} \]
\[ = z^{\ell(U^\perp) - \rho(E) + r \dim(U^\perp)} \]
\[ = z^{r \dim(U^\perp) - \rho(E)} \sum_{A : U^\perp \leq A \leq E} p(M.A; z). \]

□

We now show that for any subspace \( U \leq E \), the characteristic polynomial of \( M^*U \) is completely determined by the set \( \{(p(M.V; z), V) : V \leq E\} \).

**Corollary 58.** Let \( U \leq E \). We have the identity:

\[ z^{\rho(E)} p(M^*U; z) = \sum_{V \leq E} p(M.V; z) \sum_{j=0}^{\dim(U \cap V^\perp)} \left[ \dim(U \cap V^\perp) \right] (-1)^{\dim(U) - j} q^{(\dim(U^\perp) - j)} z^j. \]

**Proof.** From Lemma 57, we have:

\[ \sum_{A : A \leq U} p(M^*A; z) = z^{r \dim(U) - \rho(E)} \sum_{V : V \leq U} p(M.V; z). \]

(2)

Apply the Möbius inversion formula to Equation (2) to get the identity

\[ p(M^*U; z) = \sum_{A : A \leq U} \mu(A, U) z^{r \dim(A) - \rho(E)} \sum_{V : V \leq A} p(M.V; z). \]

Then

\[ z^{\rho(E)} p(M^*U; z) = \sum_{A : A \leq U} \mu(A, U) z^{r \dim(A)} \sum_{V \leq A} p(M.V; z) \]
\[ \quad = \sum_{V \leq E} p(M.V; z) \sum_{A : A \leq U \cap V^\perp} \mu(A, U) z^{r \dim(A)}. \]
\[ \quad = \sum_{V \leq E} p(M.V; z) \sum_{j=0}^{\dim(U \cap V^\perp)} \left[ \dim(U \cap V^\perp) \right] (-1)^{\dim(U) - j} q^{(\dim(U^\perp) - j)} z^j. \]

□

We now have the following MacWilliams identity, relating the weight enumerators of \( M \) and \( M^* \). This version of the identity, or rather its corollary, will be used to prove the main theorem of Section 6.

**Theorem 59.** Let \( s \in \{0, \ldots, n\} \). Then

\[ \sum_{i=0}^{n-s} \left[ \begin{array}{c} n - i \\ s \end{array} \right] A_M(i; z) = z^{\rho(E) - rs} \sum_{i=0}^{s} \left[ \begin{array}{c} n - i \\ s - i \end{array} \right] A_{M^*}(i; z). \]

**Proof.** We start with the left-hand-side of the equation and rewrite it, noting that \( \left[ \begin{array}{c} n - i \\ s \end{array} \right] q = \left[ \begin{array}{c} n - i \\ n - s - i \end{array} \right] \) counts the number of \((n-s)\)-dimensional subspaces of \( E \) that contain a fixed space of dimension \( i \). This yields:

\[ \sum_{i=0}^{n-s} \left[ \begin{array}{c} n - i \\ s \end{array} \right] A_M(i; z) = \sum_{i=0}^{n-s} \left[ \begin{array}{c} n - i \\ n - s - i \end{array} \right] \sum_{q \dim(X) = i} p(M.X; z) \]
\[ = \sum_{U : \dim(U) = n-s} \sum_{X \leq U} p(M.X; z). \]

17
From Lemma 57, this gives:
\[
\sum_{i=0}^{n-s} \binom{n-i}{s} q^i A_M(i; z) = \sum_{U: \dim(U)=n-s} z^{\rho(E)-r \dim(U^\perp)} \sum_{X \leq U^\perp} p(M^*; X; z)
\]
\[
= \sum_{V: \dim(V)=s} z^{\rho(E)-rs} \sum_{X \leq V} p(M^*; X; z)
\]
\[
= z^{\rho(E)-rs} \sum_{i=0}^{s} \binom{n-i}{s-i} q^i \sum_{X \leq E: \dim(X)=i} p(M^*; X; z)
\]
\[
= z^{\rho(E)-rs} \sum_{i=0}^{s} \binom{n-i}{s-i} A_M^*(i; z).
\]

\[\square\]

Theorem 59 shows that the weight enumerator of a \(q\)-polymatroid and that of its dual are related by invertible \(q\)-Pascal matrices. The minors of such matrices have been studied as \(q\)-analognues of the classical Pascal matrices. We will use the following result from [23, Theorem 2.2].

Lemma 60. Let \(r_1, \ldots, r_n\) be a sequence of non-negative integers. We have
\[
\det \left( \binom{r_i}{j-1} q \right)_{1 \leq i, j \leq n} = q^{\binom{n}{2}} \prod_{1 \leq i < j \leq n} \frac{q^{r_i}-q^{r_j}}{q^j - q^i}.
\]

The next corollary (c.f. [5, Corollary 3.2]) is the main device used to prove Theorem 67, which identifies sufficiency criteria for the existence of weighted subspace designs arising from the dependent spaces of a \(q\)-polymatroid (c.f. [5, Theorem 3.3]). We remark that the reasoning used here is similar to that of the original Assmus-Mattson Theorem and its generalizations. For any positive integer \(\ell\), we write \([\ell] := \{1, \ldots, \ell\}.

Corollary 61. Let \(S \subseteq \{1, \ldots, n\}\). The pair of lists
\[
[A_M^*(i; z) : |S| \leq i \leq n] \text{ and } [A_M(j; z) : j \in S],
\]
is determined uniquely by the pair of lists
\[
[A_M^*(i; z) : 1 \leq i \leq |S|-1] \text{ and } [A_M(j; z) : j \in [n] - S].
\]

Proof. Let \(A_M(z) := (A_M^*(i; z))_{0 \leq i \leq n}\) and let \(A_{M^*}(z) := (A_M^*(i; z))_{0 \leq i \leq n}\). Note that \(A_M(0; z) = A_M^*(0; z) = 1\), and in particular are known. From Theorem 59, we have the matrix equation
\[
\begin{pmatrix}
\binom{n-i}{s} q \\
\end{pmatrix}_{0 \leq i, s \leq n} A_M(z) = \text{diag}(z^{\rho(E)-rs})_{0 \leq s \leq n} \begin{pmatrix}
\binom{n-i}{s} q \\
\end{pmatrix}_{0 \leq i, s \leq n} A_{M^*}(z).
\]

Let \(t = |S|\) and write \(S = \{\ell_1, \ldots, \ell_t\}\). By Lemma 60, we have
\[
\det \begin{pmatrix}
\binom{n-\ell_i}{s-1} q \\
\end{pmatrix}_{1 \leq i, s \leq \ell} = q^{\binom{\ell}{2}} \prod_{1 \leq i < j \leq \ell} \frac{q^{n-\ell_i} - q^{n-\ell_j}}{q^j - q^i},
\]
which is non-zero, as the \(\ell_i\) are distinct. Now suppose that the coefficients \(A_M(j; z)\) are known for \(j \notin S\) and that the \(A_M^*(j; z)\) are known for \(0 \leq j \leq t-1\). Then we can solve for the unknown \(A_M^*(j; z)\) via
\[
(A_M^*(\ell_i; z))_{1 \leq i \leq \ell} = \begin{pmatrix}
\binom{n-\ell_j}{s-1} q \\
\end{pmatrix}_{1 \leq j, s \leq \ell}^{-1} \begin{pmatrix}
\text{diag}(z^{\rho(E)-rs})_{0 \leq s \leq t-1} \\
\end{pmatrix}_{0 \leq s, j \leq t-1} \begin{pmatrix}
\binom{n-j}{s} q \\
\end{pmatrix}_{0 \leq s, j \leq t-1} (A_M^*(j; z))_{0 \leq j \leq t-1}.
\]
Once the list \([A_M(j; z) : j \in S]\) is determined, since \(A_M(z)\) is now known, Theorem 59 can be applied to retrieve \([A^*_M(i; z) : t \leq i \leq n]\).

6. Weighted Subspace Designs from \(q\)-Polymatroids

6.1. Weighted Subspace Designs. In [5], the authors give a definition of a weighted subspace design, which generalizes a \(t\)-design. A \(t\)-(\(n, k, \lambda\)) design, with \(t, k, \lambda\) positive integers, is a collection of \(k\)-subsets of an \(n\)-set (called blocks) with the property that every \(t\)-subset of the \(n\)-set is contained in exactly \(\lambda\) blocks. A \(q\)-analogue of this notion is that of a \(t\)-design over \(\mathbb{F}_q\), which is a collection of \(k\)-dimensional subspaces of \(E\) called blocks, with the property that every \(t\)-dimensional subspace of \(E\) is contained in the same number of blocks. Similarly, there is a \(q\)-analogue of a weighted \(t\)-design.

**Definition 62.** Let \(G\) be an additive group, \(t, k\) positive integers and \(\lambda \in G\). A weighted \(t\)-(\(n, k, \lambda; q\)) design \(D\) is a triple \((E, \mathcal{B}, f)\) for which \(\mathcal{B}\) is a collection of \(k\)-subspaces of \(E\) (called blocks) and \(f : \mathcal{B} \rightarrow G\) is a weight function such that for all \(t\)-spaces \(T\) of \(E\), \(\sum_{B : T \leq B} f(B) = \lambda\).

We say that \(D\) is a **weighted subspace design** or is a **weighted design over \(\mathbb{F}_q\)**.

A subspace design (a design over \(\mathbb{F}_q\)) can be interpreted as a weighted subspace design with the weight function \(f(B) := 1\) for all \(B \in \mathcal{B}\), and \(G = (\mathbb{Z}, +)\). For an excellent survey on subspace designs, see [4]. In general, obtaining new subspace designs is a difficult problem, often highly dependent on computer search, which is exacerbated by the number of subspaces involved (which is exponential in comparison to classical designs for the same parameters). For example, it is not yet known if a 3-(8, 4, 1; 2) subspace design exists; such a design would have 6477 blocks, chosen from an ambient space having 200,787 4-dimensional subspaces. Its classical analogue, the extended Fano plane, has 14 blocks, chosen from a collection of 70 4-sets. In [8], a construction of a \(q\)-analogue of a perfect matroid design (\(q\)-PMD) was given, which is a \(q\)-matroid for which all flats of the same dimension have the same rank. This \(q\)-PMD yields a construction of a subspace design from a \(q\)-Steiner system. In the following sections we will show another way that subspace designs and weighted subspace designs can arise from \(q\)-polymatroids satisfying certain rigidity properties.

The **intersection numbers** of a weighted subspace design are important invariants and can be used to establish non-existence results. Their values are the same as for subspace designs; see, for example [21, Fact 1.5] or [30].

**Theorem 63.** Let \((E, \mathcal{B}, f)\) be a \(t\)-(\(n, k, \lambda; q\)) weighted subspace design and let \(I, J\) be two subspaces of \(E\) of dimension \(i\) and \(j\), respectively, such that \(I \cap J = \{0\}\). If \(i + j \leq t\), then

\[
\sum_{B : B \leq I \subset B \cap J = \{0\}} f(B) = q^{(k-i)j} \binom{n-i-j}{k-i} \binom{n-t}{k-t}_q \lambda.
\]

In particular, this number is independent of the choice of \(I\) of dimension \(i\) and \(J\) of dimension \(j\). We denote it by \(\lambda_{i,j}\).

**Proof.** If \(X\) is a subspace of \(E\) of dimension \(x \leq t\), then since \((E, \mathcal{B}, f)\) is a weighted subspace design, we have

\[
\left[\begin{array}{c}
\frac{k-x}{t-x}
\end{array}\right]_q \sum_{B \in \mathcal{B} : X \leq B} f(B) = \sum_{B \in \mathcal{B} : X \leq B} \sum_{T : X \leq T \leq B, \dim(T) = t} f(B),
\]

\[
= \sum_{T : X \leq T \leq B, \dim(T) = t} \sum_{B \in \mathcal{B} : T \leq B} f(B) = \left[\begin{array}{c}
\frac{n-x}{t-x}
\end{array}\right]_q \lambda.
\]
Now restrict to a subspace $X$ of the form $X = I + L$ for some $L \leq J$ of dimension $s$. Then $I \cap L = \{0\}$ and $\dim(I + L) = i + s$ and so (3) becomes:

$$g(L) := \sum_{B \in B : I + L \leq B} f(B) = \left[\frac{n - (i + s)}{t - (i + s)}\right]_q \left[\frac{k - (i + s)}{t - (i + s)}\right]_q \lambda.$$ 

Define $h(K) = \sum_{B \in B : I \leq B, B \cap J = K} f(B)$, for each $K \leq J$. Then we have that

$$g(L) = \sum_{K : L \leq K \leq J} h(K)$$

and so, by Möbius inversion on the lattice $\mathcal{L}(J)$,

$$h(L) = \sum_{K : L \leq K \leq J} \mu(L, K) g(K).$$

Substituting $L = \{0\}$ now gives

$$\sum_{B \in B : I \leq B, B \cap J = \{0\}} f(B) = h(\{0\}) = \sum_{K \leq J} \mu(0, K) g(K)$$

$$= \sum_{s=0}^{j} \sum_{\substack{0 \leq j \leq s \leq n \leq \infty \\text{is a valid index}}} (-1)^{s} \left[\frac{n - i - s}{t - i - s}\right]_q \left[\frac{k - i - s}{t - i - s}\right]_q \lambda$$

$$= \lambda \left[\frac{n - t}{k - t}\right]_q \left[\frac{j}{s}\right] \sum_{s=0}^{j} (-1)^{s} \left[\frac{n - i}{k - i}\right]_q \left[\frac{n - j}{k - j}\right]_q$$

The third line follows from applying Equation (1) with $a = n - i - s, b = k - i - s, c = t - i - s$, and the last equality follows from Lemma 20.

The proof outlined above is a direct $q$-analogue of [5, Theorem 2.6]. The intersection numbers for subspace designs were given in [12, 30], for which the authors proposed an inductive argument.

We have the following constructions of weighted subspace designs from a given one (c.f. [21, 30]).

**Corollary 64.** Let $D := (E, B, f)$ be a weighted $t$-$(n, k, \lambda; q)$ design.

1. For $0 \leq i \leq t$, $D$ is an $i$-$(n, k, \lambda; q)$ weighted subspace design with

$$\lambda_i = \left[\frac{n - i}{k - i}\right]_q \left[\frac{n - t}{k - t}\right]_q \lambda = \left[\frac{n - i}{t - i}\right]_q \left[\frac{k - i}{t - i}\right]_q \lambda.$$

2. Define $B^\perp := \{B^\perp : B \in B\}$. If $k \leq n - t$ then $D^\perp = (E, B^\perp, f^\perp)$ is a $t$-$(n, n - k, \lambda^\perp; q)$ weighted subspace design with $f^\perp(B^\perp) := f(B)$ for all $B \in B$ and $\lambda^\perp := \left[\frac{n - k}{t}\right]_q \left[\frac{k}{t}\right]_q \lambda$.

**Proof.** To see that (1) holds, apply Theorem 63 with $\lambda_i := \lambda_{i,0}$. Let $I$ be an $i$-dimensional subspace of $E$. We have $\lambda_{i,0} = \sum_{B \in B : t \leq B} f(B) = \left[\frac{n - i}{k - i}\right]_q \left[\frac{n - t}{k - t}\right]_q \lambda$. The rest follows from Equation (1).

We will compute the value $\lambda^\perp$. A $t$-dimensional subspace $T$ is contained in $B^\perp \in B^\perp$ if and only if $B \leq T^\perp$. Now consider the set $S := \{(B, X) : B \in B, \dim(X) = n - t, B \leq X\}$. We
will compute the sum of the \( f(B) \) over all pairs \((B, X)\) in \( S\) in two ways. On the one hand, we have:

\[
\sum_{(B,X) \in S} f(B) = \sum_{B \in B} \sum_{X : B \leq X \atop \dim(X) = n-t} f(B) = \binom{n-k}{t} \sum_{B \in B} f(B) = \binom{n-k}{t} \lambda_{0,0}.
\]

The last equality follows from applying Equation (1) with \( a = n, b = k, c = t \). On the other hand,

\[
\sum_{(B,X) \in S} f(B) = \sum_{X \in E : \dim(X) = n-t} \sum_{B : B \leq X} f(B) = \binom{n}{t} \sum_{B \in B, B \leq X} f(B).
\]

It follows, by comparing the two right-hand sides, that

\[
\lambda^\perp := \sum_{B^* \in B^*, T \leq B^\perp} f(B) = \sum_{B \in B, B \leq T} f(B) = \binom{n-k}{t} \binom{k}{t}^{-1} \lambda.
\]

\[\square\]

6.2. Subspace Designs from \( q \)-Polymatroids. We now present criteria for the existence of a weighted subspace design arising from the dependent spaces of a \( q \)-polymatroid. The approach is in essence a generalization of the original argument given by Assmus and Mattson [1]. To do this, we obtain a \( q \)-analogue of [5, Theorem 3.3]. Throughout this section we let \( \mathbb{F} \) denote an arbitrary field. Since \( p(M;z) \in \mathbb{Z}[z] \), it gives a well-defined function on any field, viewed as a \( \mathbb{Z} \)-module. We define the following (c.f. [5]).

**Definition 65.** Let \( \theta \in \mathbb{F} \). We define:

- \( D_M(i; \theta) := \{ X \leq E : \dim(X) = i, p(M.X; \theta) \neq 0 \} \),
- \( R_M(t; \theta) := \{ j \in \{1, \ldots, n-t \} : A_{M^*}(j; \theta) \neq 0 \} \),
- \( d_M := \min \{ \dim(X) : X \leq E, X \text{ is a cocircuit of } M \} \).

The sets \( D_M(i; \theta) \) will, in certain circumstances, form the blocks of weighted subspace designs.

**Proposition 66.** Let \( \theta \in \mathbb{F} \) such that \( \theta^s \neq 1 \) for any \( s \in \{1, \ldots, r\} \). For each \( i \in \{1, \ldots, n\} \) every member of \( D_M(i; \theta) \) is a dependent space of \( M^* \). Moreover \( D_M(d_M; \theta) \) is precisely the set of circuits of \( M^* \) of dimension \( d_M \).

**Proof.** If \( A \in D_M(i; \theta) \), then \( p(M.A; \theta) \neq 0 \), which by Lemma 29 means that \( A \) is a dependent space of \( M^* \). We show that for circuits of \( M^* \) (i.e., minimal dependent spaces of \( M^* \)) the converse also holds. By Lemma 30, for any circuit \( X \) of \( M^* \) we have \( p(M.X; z) = z^{\ell(X^*)} - 1 \). Since \( X \) is not independent in \( M^* \), \( \ell(X^*) > 0 \) by Lemma 28. Therefore, by our choice of \( \theta \), we have that \( p(M.X; \theta) = \theta^{\ell(X^*)} - 1 \neq 0 \) and so \( X \in D_M(\dim(X); \theta) \). In particular, \( D_M(d_M; \theta) \) is precisely the set of all circuits of \( M^* \) of dimension \( d_M \). \( \square\)

We will now present the main results of this section: Theorem 67 and its two corollaries. Together they form a \( q \)-analogue of [5, Theorem 3.3].

**Theorem 67.** Let \( \theta \in \mathbb{F} \) such that \( \theta^s \neq 1 \) for any \( s \in \{1, \ldots, r\} \). Let \( t < d_M \) be a positive integer. Suppose that \( \sigma^* := |R_M(t; \theta)| \leq d_M - t \) and suppose further that for each \( t \)-dimensional subspace \( T \) and \( j \leq n-t \), if \( A_{M^*}(j; \theta) = 0 \), then \( A_{M^*}(T;j; \theta) = 0 \). Then (\( E, D_M(d_M; \theta), f \)) is a weighted \( t \)-design over \( \mathbb{F}_q \) with \( f(X) := p(M.X; \theta) \).

**Proof.** Let \( T \) be a \( t \)-dimensional subspace of \( E \). Since \( t < d_M \), \( T \) is independent in \( M^* \). By Lemma 15, any dependent space \( A \) of \( M^*/T \) has the form \( A = B/T \) for a dependent space \( B \) of \( M^* \). Therefore, for any such \( A \) and \( B \) we have

\[
\sigma^* \leq d_M - t \leq \dim(B) - t = \dim(A).
\]

\[\tag{4}\]
In other words, no dependent space of $M^*/T$ has dimension less than $\sigma^*$. By Lemma 29, if $X$ is non-trivial and independent in $M^*/T$, then $p((M^*/T)^*X; \theta) = 0$. Therefore,

$$A_{(M^*/T)^*}(i; \theta) = \sum_{X \leq E/T: \dim(X) = i} p((M^*/T)^*X; \theta) = 0, \text{ for all } 1 \leq i \leq \sigma^* - 1.$$ 

By hypothesis, $A_{M^*/T}(j; \theta) = 0$ for all $j \notin R_M(t; \theta)$, $j \leq n - t$ and so the coefficients,

$$[A_{M^*/T}(j; \theta) : j \notin R_M(t; \theta), j \leq n - t] \text{ and } [A_{(M^*/T)^*}(i; \theta) : 1 \leq i \leq \sigma^* - 1],$$

are known. Now write $S = R_M(t; \theta)$ and apply Corollary 61 to see that the coefficients

$$[A_{M^*/T}(j; \theta) : j \in R_M(t; \theta)] \text{ and } [A_{(M^*/T)^*}(i; \theta) : \sigma^* \leq i \leq n - t]$$

are uniquely determined and independent of our choice of $T$ of dimension $t$. It follows that the $A_{(M^*/T)^*}(i; \theta)$ are uniquely determined for $0 \leq i \leq n - t$. We will now show that

$$\sum_{X \in D_M(d_M; \theta); T \leq X} p(M.X; \theta) = A_{(M^*/T)^*}(d_M - t; \theta),$$

which will establish that $(E, D_M(d_M; \theta), f)$ is a weighted $t$-design over $\mathbb{F}_q$ with $f(X) := p(M.X; \theta)$.

We claim there is a one-to-one correspondence between the members of $D_M(d_M; \theta)$ that contain $T$ and the members of $D_{(M^*/T)^*}(d_M - t; \theta)$. Let $B$ be a circuit of $M^*$ that contains $T$ such that $\dim(B) = d_M$. From Lemma 15, $B/T$ is a circuit of $M^*/T$ and $\dim(B/T) = \dim(B) - t = d_M - t$. Conversely, if $A$ is a circuit of $M^*/T$ satisfying $\dim(A) = d_M - t$, then $A = B/T$ for a dependent space $B$ of $M^*$ of dimension $\dim(B) = d_M$, which is therefore a circuit of $M^*$, as it has minimal dimension. By Proposition 66, $D_M(d_M; \theta)$ is the set of all cocircuits of $M$ of dimension $d_M$ and hence there is a one-to-one correspondence between the members of $D_M(d_M; \theta)$ that contain $T$ and the circuits of $M^*/T$ of dimension $d_M - t$. By Equation (4), any dependent space of $M^*/T$ of dimension $d_M - t$ is a circuit of $M^*/T$ and hence is a member of $D_{(M^*/T)^*}(d_M - t; \theta)$. This establishes the claim.

From Corollary 33, for any circuit $X/T$ of $M^*/T$ we have

$$p((M^*/T)^*X/T; \theta) = \theta^{\ell(X^\perp)} - 1.$$ 

Therefore,

$$\sum_{X \in D_M(d_M; \theta); T \leq X} p(M.X; \theta) = \sum_{X \in D_M(d_M; \theta); T \leq X} (\theta^{\ell(X^\perp)} - 1),$$

$$= \sum_{X/T \in D_{(M^*/T)^*}(d_M - t; \theta)} (\theta^{\ell(X^\perp)} - 1),$$

$$= \sum_{X/T \leq E/T: \dim(X/T) = d_M - t} p((M^*/T)^*X/T; \theta),$$

$$= A_{(M^*/T)^*}(d_M - t; \theta),$$

which is independent of our choice of $T$ of dimension $t$. It follows that $(E, D_M(d_M; \theta), f)$ is a weighted $t$-design over $\mathbb{F}_q$ with $f(X) := p(M.X; \theta)$.

**Remark 68.** In the proof of Theorem 67, we saw that with the hypothesis of the theorem, that the $A_{(M^*/T)^*}(i; \theta)$ (and therefore the $A_{M^*/T}(i; \theta)$) are uniquely determined for $0 \leq i \leq n - t$. By Lemma 11, it follows that the $A_{M^*/T}(i; \theta)$ are uniquely determined for $0 \leq i \leq n - t$.

**Corollary 69.** Let $\theta \in \mathbb{F}$ such that $\theta^s \neq 1$ for any $s \in \{1, \ldots, r\}$. Let $t < d_M$ be a positive integer. Suppose that $\sigma^* := |R_M(t; \theta)| \leq d_M - t$ and suppose further that for each $t$-dimensional subspace $T$ and $j \in \{d_M, \ldots, n - t\}$, if $A_M(j; \theta) = 0$ then $A_{M^*/T}(j; \theta) = 0$. Then for each $j \in \{d_M, \ldots, n - t\}$, $(E, D_M(j; \theta), f)$ is a weighted $t$-design over $\mathbb{F}_q$ with $f(X) := p(M.X; \theta)$. 

Proof. We will prove by induction on \( w \in \{ d_M, \ldots, n - t \} \) that \((E, D_M(w; \theta), f)\) is a weighted \( t \)-design. The first step was proved in Theorem 67. Suppose now that \((E, D_M(j; \theta), f)\) is a weighted \( t \)-design for each \( j \in \{ d_M, \ldots, w - 1 \} \). We will show that \((E, D_M(w; \theta), f)\) is also a weighted \( t \)-design.

Let \( T \leq E \) have dimension \( t \). We will show that the following sum depends only on \( t \):

\[
\sum_{W \in D_M(w; \theta), T \leq W} p(M; W; \theta) = \sum_{W : T \leq W, \dim(W) = w} p(M; W; \theta).
\]

Note that since \( D_M(w; \theta) \) is the set of \( w \)-dimensional subspaces of \( E \) for which \( p(M; W; \theta) \neq 0 \), the above equality holds. From Lemma 34, for any \( T \leq W \leq E \) we have that

\[
p(M|T^\perp/W^\perp; \theta) = \sum_{A : A + T = W} p(M; A; \theta).
\]

Let \( \phi : \mathcal{L}(E/T) \rightarrow \mathcal{L}(T^\perp) \) be defined by \( \phi(A/T) = (A^\perp)^\perp(T^\perp) \), for each \( A \leq E \) such that \( T \leq A \). (This map was already used in Lemma 11.) Let \( X \) be such that \( \phi(W/T) = X \). Then \( (W^\perp)^\perp(T^\perp) = X \) and so \( X^\perp = W^\perp \). Therefore, \( M|T^\perp.X = (M|T^\perp)/W^\perp \). Clearly, \( \dim(W) = \dim(X) + \dim(T) \) and so if \( T \) is a \( t \)-dimensional space, then:

\[
A_{M|T^\perp}(j; z) = \sum_{X \leq T^\perp : \dim(X) = j} p(M|T^\perp.X; z) = \sum_{W \leq E : T \leq W, \dim(W) = j + t} p(M|T^\perp/W^\perp; z).
\]

Therefore we have

\[
A_{M|T^\perp}(w - t; \theta) = \sum_{W : t \leq W, \dim(W) = w} p(M|T^\perp/W^\perp; \theta) = \sum_{W : t \leq W, \dim(W) = w} \sum_{A : A + T = W} p(M; A; \theta).
\]

For any \( I \leq T \), we write \( I_T \) to denote an arbitrary fixed subspace of \( T \) satisfying \( I \oplus I_T = T \). Clearly, if \( I = A \cap T \) we have \( I \leq A \) and \( A \cap I_T = \{0\} \). Conversely, if \( I \leq A \) and \( I_T \cap A = \{0\} \) then \( A \cap T = A \cap (I + I_T) = I \). Moreover, if \( W \) is a \( w \)-dimensional subspace for which \( A + T = W \) and \( A \cap T = I \), then \( \dim(A) = w - t + \dim(I) \). Therefore, we can rewrite the double summation as follows:

\[
A_{M|T^\perp}(w - t; \theta) = \sum_{i = 0}^{t} \sum_{I : I \leq T, \dim(I) = i} \sum_{A : I \leq A, I_T \cap A = \{0\}, \dim(A) = w - t + i} p(M; A; \theta)
\]

\[= \sum_{A : I \leq A, I_T \cap A = \{0\}, \dim(A) = w - t + i} p(M; A; \theta) + \sum_{i = 0}^{t - 1} \sum_{I : I \leq T, \dim(I) = i} \sum_{A : I \leq A, I_T \cap A = \{0\}, \dim(A) = w - t + i} p(M; A; \theta).
\]

Let \( I \leq T \) such that \( \dim(I) = i < t \) and so \( d_M - t \leq w - t \leq w - t + i \leq w - 1 \). By hypothesis, for each \( 1 \leq j \leq w - 1 \), \((E, D_M(j; \theta), f)\) is a weighted \( t \)-design with \( f(X) := p(M; X; \theta) \), and so by Theorem 63,

\[
\sum_{A : I \leq A, I_T \cap A = \{0\}, \dim(A) = w - t + i} p(M; A; \theta) = \Lambda_{w,t-i}^w(M; \theta),
\]

for \( \Lambda_{w,t-i}^w(M; \theta) \) that depend only on \( t, w, i \). It follows that

\[
\sum_{W : T \leq W, \dim(W) = w} p(M; W; \theta) = A_{M|T^\perp}(w - t; \theta) - \sum_{i = 0}^{t - 1} \sum_{I : I \leq T, \dim(I) = i} \Lambda_{w,t-i}^w(M; \theta).
\]

By Remark 68, \( A_{M|T^\perp}(w - t; \theta) \) is independent of our choice of \( T \) of dimension \( t \) and so the result follows. \( \square \)
Corollary 70. Let $\theta \in \mathbb{F}$ such that $\theta^* \neq 1$. Let $t < d_M$ be a positive integer. Suppose that $\sigma^* := |R_M(t; \theta)| \leq d_M - t$ and suppose further that for each $t$-dimensional subspace $T$ and $j \leq n-t$, if $A_{M^*}(j; \theta) = 0$, then $A_{M^*,T}(j; \theta) = 0$. Then for each $j \in \{d_M, \ldots, n-t\}$, $(E, D_{M^*}(j; \theta), f^*)$ is a weighted $t$-design over $\mathbb{F}_q$ with $f^*(X) := p(M^*.X; \theta)$ for all subspaces $X \leq E$.

Proof. For each $d_M \leq j \leq n-t$, define the set $D_j := \{X^\perp : X \in D_{M^*}(j; \theta)\}$. Let $T$ be a $t$-dimensional subspace of $E$. Then for each $j$ we have:

$$\sum_{X \in D_{M^*}(j; \theta) : T \leq X^\perp} p(M^*.X; \theta) = \sum_{X : X^\perp \leq T^\perp, \dim(X) = j} p(M^*.X; \theta) = \sum_{X : X^\perp \leq T^\perp, \dim(X) = j} p(M^*/X^\perp; \theta).$$

Now for each $X \leq T^\perp$ we have $(E/T)/(X^\perp/T) \cong E/X^\perp$ and it is easy to see that the corresponding $q$-polymatroids are lattice-equivalent. Then, applying Lemma 11 and using the fact that $\phi(X^\perp/T)/(X^\perp/T) \cong X^\perp$, we get

$$M^*.X \cong (M^*/T)/(X^\perp/T) \cong (M|T^\perp)^* \phi(X^\perp/T) = (M|T^\perp)^* \phi(X^\perp/T | T^\perp) \cong (M|T^\perp)^*.X.$$

Therefore,

$$\sum_{X \in D_j : T \leq X} p(M^*.X; \theta) = \sum_{X : T \leq X, \dim(X) = n-j} p((M|T^\perp)^*.X; \theta) = A(M|T^\perp)^*(n-j; \theta).$$

From Remark 68, $A(M|T^\perp)^*(n-j; \theta)$ is independent of the choice of $T$ of dimension $t$. It follows that $(E, D_j, f^*)$ is a weighted subspace design with $f^*$ defined by $f^*(X) = p(M^*.X; \theta)$ for each $X \leq E$. The result now follows by Corollary 64: the required subspace design is the dual of $(E, D_j, f^*)$.

Remark 71. The results of Proposition 66, Theorem 67 and Corollaries 69 and 70 all hold with indeterminate $z$ in place of a specific choice of $\theta$ in $\mathbb{F}$. In particular, $p(M.X; z)$ is a non-zero polynomial in $\mathbb{Z}[x]$ for any cocircuit $X$ of $M$.

In general, a $(q, r)$-polymatroid $M$ may satisfy the hypothesis of Corollary 69 for one choice of $\theta$, but fail for another choice. However, if the hypothesis holds for indeterminate $z$, then a weighted $t$-design over $\mathbb{F}_q$ can be constructed for any choice of $\theta$ that doesn’t vanish on $p(M.X; z)$ for a cocircuit $X$ of $M$.

Example 72. Let $M = (E, \rho)$ be the uniform $q$-matroid $U_{k,n}$, as described in Example 16. We will show that this $q$-matroid satisfies the hypothesis of Corollary 69 with indeterminate $z$ in place of a specific choice of $\theta$ in some field $\mathbb{F}$.

The dual $q$-matroid $M^* = (E, \rho^*)$ is the uniform $q$-matroid $U_{n-k,n}$, whose independent spaces are exactly those of dimension $n-k$ or less, and for which all other spaces are dependent and have rank $n-k$. Therefore, every cocircuit of $M$ has dimension $d_M = n-k+1$. Now $p(M^*.X; z) = 0$ for all subspaces $X$ such that $1 \leq \dim(X) \leq k$, as these are the independent spaces of $M$ (see Lemma 29), and so $A_{M^*}(i; z) = 0$ for all $i \in \{1, \ldots, k\}$. Therefore for any $t \leq d_M - 1 = n - k$, we have $R_M(t; z) \subseteq \{k+1, \ldots, n-t\}$ and so $|R_M(t; z)| \leq n-t \leq d_M - t$.

We now show that for any indeterminate $z$ the condition holds that for all $j \leq n-t$, if $A_{M^*}(j; z) = 0$, then $A_{M^*,T}(j; z) = 0$. Let $T$ be a $t$-dimensional subspace of $E$ and recall $1 \leq t \leq n-k$. By Lemma 44 we have

$$A_{M^*,T}(j; z) = \sum_{X \leq T^\perp, \dim(X) = j} p(M^*.X; z).$$

Since $p(M^*.X; z) = 0$ for all subspaces $X$ such that $1 \leq \dim(X) \leq k$, we have that $A_{M^*}(j; z) = 0$ for all $j \in \{1, \ldots, k\}$.

Next, we consider the case $k+1 \leq j \leq n-t$. Let $X \leq E$ be a subspace of dimension at least $k+1$. We claim that the $q$-matroid $M^*.X$ has no loops, in which case by Lemma 39, $p(M^*.X; z)$ will be a monic polynomial of degree $n-k - \dim(X^\perp)$ and hence $A_{M^*}(j; z) \neq 0$.
for \( k+1 \leq j \leq n-1 \), i.e. the condition holds vacuously. Consider a subspace \( U \) that strictly contains \( X^\perp \). Since \( M^* = U_{n-k,n} \), we have \( \rho^*(X^\perp) = \dim(X^\perp) \) and so
\[
\rho_{M^*/X^\perp}(U/X^\perp) = \rho^*(U) - \rho^*(X^\perp)
\]
\[=
\rho^*(U) - \dim(X^\perp)
\]
\[= \dim U - \rho(E) + \rho(U^\perp) - \dim(X^\perp)
\]
\[= \dim U - \dim X^\perp + \rho(U^\perp) - k
\]
We have that \( \rho(U^\perp) = \min\{\dim U^\perp, k\} \). Substituting both cases in the equation above and using that \( \dim X - k \geq 1 \) and \( \dim U - \dim X^\perp \geq 1 \), respectively, we find that \( \rho_{M^*/X^\perp}(U/X^\perp) \geq 1 \).

This implies that the \( q \)-matroid \( M^* \).X has no loops.

We conclude that \( M = U_{k,n} \) satisfies the hypothesis of Corollary 69 for indeterminate \( z \).

Therefore for any \( \theta \in \mathbb{F} \) such that \( \theta^* \neq 1 \), \( 1 \leq s \leq r \). \((E,D_{U_{k,n}}(i;\theta),f)\) is a weighted \( t \)-design for \( 1 \leq i < n-k \), and \( f(X) = p(U_{k,n};X;\theta) \) for all \( X \in D_{U_{k,n}}(i;\theta) \).

6.3. Further Implications. We now obtain a weaker form of the Assmus-Mattson Theorem for matrix codes as a direct consequence of Theorem 67. Note that the result for subspace designs (those weighted designs for which \( f(B) = 1 \) for every block \( B \) obtained from rank-metric codes was shown in [10] with the further assumption that the number of codewords with a given support was dependent only on the dimension \( i \) of that space for some range of \( i \).

**Corollary 73.** Let \( C \) be an \( \mathbb{F}_q[n \times m,k,d] \) rank-metric code. Let \( t < d \) be a positive integer and let \( C^\perp \) have no more than \( d-t \) distinct rank weights in the set \( \{1,\ldots,n-t\} \). For each \( i \in \{d,\ldots,n-t\} \), let
\[
B(i) = \{U \leq E : \dim(U) = i,|C_{U^\perp}| \neq 0\}.
\]
Then for each \( i \in \{d,\ldots,n-t\} \), \((E,B(i),f)\) is a weighted \( t \)-design over \( \mathbb{F}_q \) with \( f(X) := |C_{X^\perp}| \).

**Proof.** Let \( M := M_C \). By Lemma 49, we have that \( M^* = M_{C^\perp} \) and for any \( i \in \{1,\ldots,n\} \), \( W_i(C^\perp) = A_{M^*}(i;q) \). Also, \( p(M.X;q) = |C_{X^\perp}| \) for any subspace \( X \leq E \). Now \( d_M = \min\{\dim X : X \) is a cocircuit of \( M \}, \) which by Proposition 66, is the minimum dimension of any subspace \( X \) such that \( p(M.X;q) = 0 \).

Since \( C \) has minimum distance \( d \), by Lemma 49 (4) there exists a \( d \)-dimensional subspace \( X \leq E \) such that \( |C_{X^\perp}| = p(M.X;q) \neq 0 \), while \( p(M.U;q) = 0 \) for every subspace \( U \leq E \) with \( \dim(U) < d \). Therefore, \( d_M = d_H \). By hypothesis, at most \( d-t = d_M - t \) of the integers \( W_i(C^\perp) \) are non-zero for \( i \in \{1,\ldots,n-t\} \). By Lemma 49, if \( A_{M^*}(i;\theta) = 0 \), then \( A_{M^*}(i;\theta) = 0 \), for any \( t \)-dimensional subspace \( T \leq E \). Therefore \( M \) satisfies the hypothesis of Corollary 69 and so the result follows.

In the case of a \( q \)-matroid \( M \) satisfying the hypothesis of Theorem 67, with an extra assumption on the cocircuits of \( M \), our results imply the existence of a subspace design. These results form a direct \( q \)-analogue of the classical case (c.f. [5, Section 3]).

**Lemma 74.** Let \( M \) be a \( q \)-matroid, \( \theta \in \mathbb{F}, \theta \neq 1 \) and let \( p \) be the greatest integer such that any subspace \( X \leq E \) of dimension at most \( p \) contains at most one cocircuit of \( M \). Then, for each \( i \in \{d_M,\ldots,p\} \), we have \( D_M(i;\theta) = \{C \leq E : C \) is a cocircuit of \( M, \dim(C) = i\}. \)

**Proof.** If \( C \) is a cocircuit of \( M \), then \( p(M.C;\theta) = \theta - 1 \neq 0 \) and so \( C \in D_M(\dim(C);\theta) \). Now let \( X \in D_M(i;\theta) \) for some \( i \leq p \). Then \( p(M.X;\theta) \neq 0 \) and \( X \) is a dependent space of \( M^* \) of dimension at most \( p \), so \( X \) contains a unique circuit of \( M^* \). By Theorem 41, we have \( X = C \) and the result follows.

**Corollary 75.** Let \( M \) be a \( q \)-matroid that has at least one circuit and one cocircuit. Let \( t < d_M \) be a positive integer such that the hypothesis of Theorem 67 holds for some \( \theta \in \mathbb{F}, \theta \neq 1 \). Let \( p \) be the greatest integer such that any subspace \( X \leq E \) of dimension at most \( p \) contains at most one cocircuit (respectively, at most one circuit) of \( M \). Then for each \( i \in \{d_M,\ldots,p\} \) (respectively, \( \{d_M^*,\ldots,p\} \)) the set of cocircuits (respectively, the set of circuits) of \( M \) of dimension \( \min\{i,n-
\( t \) forms the blocks of a \( t \)-subspace design. Consequently, for each \( i \in \{d_M, \ldots, p\} \) (respectively, \( \{d_M^*, \ldots, p\} \)), the set of hyperplanes of \( M \) (respectively, of \( M^* \)) of dimension \( n - i \) forms the blocks of a \( t \)-subspace design.

Proof. From Corollary 74, for each \( i \in \{d_M, \ldots, p\} \) we have that \( C_i := D_M(i; \theta) \) is the set of cocircuits of \( M \) of dimension \( i \). Then by Corollary 69, for each \( i \in \{d_M, \ldots, p\} \), \( C_i \) is the set of blocks of a weighted \( t \)-subspace design with \( f(X) = p(M.X; \theta) = \theta - 1 \). Define a function \( \tilde{f} : D_M(i; \theta) \to \mathbb{F} \) by \( \tilde{f}(X) = (\theta - 1)^{-1} f(X) \). This yields a \( t \)-subspace design \( D_i \) whose blocks are \( C_i \). By [9, Corollary 71], for each \( i \)-dimensional cocircuit \( X \) of \( M \), \( X^\perp \) is a hyperplane of \( M \) and has dimension \( n - i \). By Corollary 64, the set of hyperplanes of \( M \) of dimension \( n - i \) form the blocks of a \( t \)-subspace design, i.e., the dual design of \( D_i \). With the same arguments as above, by Corollary 70 the analogous statements hold for the circuits of \( M \) and the hyperplanes of \( M^* \). \( \square \)

An element \( c \) of an \( \mathbb{F}_{q^m} \cdot [n, k, d] \) vector rank-metric code \( C \) is called minimal if for any \( c' \in C \), \( \sigma(c') \leq \sigma(c) \implies c' \in \langle c \rangle_{\mathbb{F}_{q^m}} := \{uv : u \in \mathbb{F}_{q^m}\} \). In this case, for \( U = \sigma(c) \), we have \( p(M.X; q^m) = |C = U| = q^m - 1 \). If every codeword of rank \( i \) in \( C \) is minimal, then \( A_{M^*}(i; \theta) = W_{i}(C^\perp) = (q^m - 1) |D_M(i; q^m)| \). If we apply this with Corollary 75, we retrieve the Assmus-Mattson Theorem for \( \mathbb{F}_{q^m} \cdot [n, k, d] \) codes (c.f. [10]).

Corollary 76. Let \( C \) be an \( \mathbb{F}_{q^m} \cdot [n, k, d] \) code. Let \( t < d \) be a positive integer and let \( C^\perp \) be an \( \mathbb{F}_{q^m} \cdot [n, n-k, d^\perp] \) code having no more than \( d - t \) distinct rank weights in the set \( \{1, \ldots, n-t\} \). Let \( p \) be the greatest integer such that every codeword of \( C \) of rank at most \( p \) is minimal.

1. The supports of the words of rank \( d \) in \( C \) (respectively \( d^\perp \) in \( C^\perp \)) form the blocks of a \( t \)-design over \( \mathbb{F}_q \).
2. For each \( i \in \{d, \ldots, p\} \) (respectively, \( \{d^\perp, \ldots, p\} \)) the supports of the minimal codewords of \( C \) (respectively \( C^\perp \)) of dimension \( \min\{i, n-t\} \) form the blocks of a \( t \)-design over \( \mathbb{F}_q \).

Example 77. In [27, Theorem 12], it is shown that any non-degenerate \( \mathbb{F}_{q^m} \cdot [N, k > 1] \) rank-metric code with constant weight \( d \) satisfies \( N = km \), \( d = m \) and is generated by a matrix \( G \in \mathbb{F}_{q^m}^{k \times N} \) whose columns form a basis of \( \mathbb{F}_{q^m}^k \) as an \( \mathbb{F}_q \)-vector space. Moreover, the dual code has minimum distance 2. Let \( C^\perp \) be an \( \mathbb{F}_{q^m} \cdot [km, k, m] \) constant weight code constructed as above. Let \( M = M_C \), so that \( M^* = M_{C^\perp} \). For any \( X \leq \mathbb{F}_{q^m}^k \), we have \( p(M.X; q^m) = 0 \) unless \( X \) is the support of a codeword of \( C^\perp \), in which case \( \dim(X) = m \). Therefore, \( A_{M^*}(m; q^m) = 0 

\[ q^{km} - 1 \], \( A_{M^*}(0; q^m) = 1 \) and \( A_{M^*}(i; q^m) = 0 \) for \( i \neq 0, m \). Then \( d_M = d = 2 \) and \( R_M(2; \theta) = \{m\} \). Therefore, by Corollary 76 the cocircuits of \( M \) of dimension 2, which are the supports of codewords of rank 2, form a 1-design over \( \mathbb{F}_q \). Similarly, the supports of the words of rank \( m \) in \( C^\perp \) form the blocks of a 1-design over \( \mathbb{F}_q \), in fact a 1-(\( km, m, 1; q \)) design, which is a \( q \)-Steiner system, whose blocks form a spread in \( \mathbb{F}_{q^m}^{km} \).

While Theorem 67 has considerable potential for constructing weighted subspace designs, utilizing it requires constructions of a \( q \)-polymatroid \( M \) whose weight enumerator takes few non-zero values and whose cocircuits have large enough dimension. Most \( q \)-matroids and \( q \)-polymatroids are not representable, however those that are, i.e. those that can be represented by rank metric codes, offer more tangible constructions.

In order to search for examples of rank-metric codes satisfying the conditions in Corollary 76 we implemented in Magma [3] a search through random \( \mathbb{F}_{q^m} \cdot [n, k, d] \) rank metric codes, for different values of \( m, n, k \) and \( t = 2 \). We make some remarks on the parameters of potentially interesting codes.

A matrix code is called maximum rank distance (MRD) if it has parameters \( \mathbb{F}_{q} \cdot [n \times m, k, d] \) with \( k = \max\{m, n\} \min\{n, m\} - d + 1 \). The MRD \( \mathbb{F}_{q^m} \)-linear codes have parameters \( \mathbb{F}_{q^m} \cdot [n, n - d + 1, k] \). MRD codes do satisfy the criteria of Corollaries 73 and 76 and there are several constructions of them. However, the corresponding subspace designs associated with these codes are trivial. We therefore would exclude them from our search space. Note that, as
either $m$ or $q$ grow asymptotically, the $\mathbb{F}_{q^m}$-linear MRD codes are dense in the space of linear codes (see for example [11, 25]), just as MDS codes are dense as $q$ becomes large. However, for small values of $q$ and $m$, we do not necessarily have a high probability of a random code being MRD, and this was checked and confirmed for all sets of parameters chosen for experiments. We also have modest constraints on the sizes of $m, n$ to exclude trivialities. For example with $t = 2$, we require that $d \geq 3$. If $m \leq 4$ and $d = 3$, then to find a suitable code $C$, we would require $C^\perp$ to be a one-weight code. However, by [10, Proposition 4.6], the dual code of a constant weight $\mathbb{F}_{q^m}[n \times m, k]$ code has minimum distance at most 2. If $m = 4 = d$, then $C$ must be a one-weight code and so $C^\perp$ has weight at most 2, which would not yield interesting results. We therefore set $m > 4$ in order to meet the criteria of Corollary 76. This means that we search for linear codes over alphabets of size at least $2^5$. In most experiments, we chose $m = n - 1$ or $m = n$ to increase the probability of satisfying the criteria.

Each code is given by a generator matrix in standard form for a linear code, i.e. $(I_k | A)$, where $A$ goes through the space of $k \times (n - k)$-matrices with entries in $\mathbb{F}_2^m$, up to equivalence under the action of the Galois group $\text{Gal}(\mathbb{F}_{2^m}/\mathbb{F}_2)$. This yields a search space of size $2^{m(k(n-k)-1)}$ matrices, which is quickly out of reach of a computer, even for small values of $k$ and $n$. Ideally, a single representative in each equivalence class for the underlying $q$-polymatroids should be computed, but it is not clear to us how to pre-compute these representatives such that running the search would be more time effective.

In our algorithm, we first compute the weight distribution of the rank metric code by going through all code words (up to a scalar) and then we deduce the weight distribution of the dual code by using the MacWilliams identities. The code is publicly available [7]. For each set of parameters, we ran the code on a different core of an 40GHz Intel Xeon E5-2640 processor, and we set a timeout of 16 days for each run. The number of codes that we were able to check in this way are given in the fifth column of Table 1.

| $m$ | $n$ | $k$ | no. of codes checked | % of search space |
|-----|-----|-----|----------------------|------------------|
| 5   | 6   | 2   | 405,285,656          | 0.125            |
| 6   | 6   | 2   | 146,666,189          | 3.334 $\times 10^{-3}$ |
| 6   | 6   | 3   | 442,349              | 1.572 $\times 10^{-9}$ |
| 6   | 8   | 2   | 44,700,000           | 6.058 $\times 10^{-13}$ |
| 7   | 8   | 2   | 13,800,000           | 9.132 $\times 10^{-17}$ |
| 8   | 8   | 2   | 3,800,000            | 1.228 $\times 10^{-20}$ |

Table 1. Random search through $\mathbb{F}_{q^m}[n, k, d]$ random rank metric codes

While a complete search is far from complete, these numbers suggest that a more systematic search for higher parameter values would be needed to effectively construct examples of rank metric codes yielding weighted subspace designs. More generally, what is really required is a theoretical approach to construct rank-metric codes and $q$-(poly)matroids with prescribed weight distributions.

7. Acknowledgements

The authors would like to say thanks to Elif Saçıkara for many useful discussions in the preparation of this work. The authors are grateful to Heide Gluesing-Luerssen and Benjamin Jany for their helpful remarks on $q$-polymatroid equivalence. This paper stems from a collaboration that was initiated at the Women in Numbers Europe (WIN-E3) conference, held in Rennes, August 26-30, 2019. The authors are very grateful to the organisers: Sorina Ionica, Holly Krieger, and Elisa Lorenzo García, for facilitating their participation at this workshop, which was supported by the Henri Lebesgue Center, the Association for Women in Mathematics (AWM) and the Clay Mathematics Institute (CMI).
