THE BEAUVILLE-NARASIMHAN-RAMANAN CORRESPONDENCE FOR TWISTED HIGGS V-BUNDLES AND COMPONENTS OF PARABOLIC SP(2n, R)-HIGGS MODULI

GEORGIOS KYDONAKIS, HAO SUN AND LUTIAN ZHAO

ABSTRACT. We generalize the classical Beauville-Narasimhan-Ramanan correspondence to the case of parabolic Higgs bundles with regular singularities and Higgs V-bundles. Using this correspondence along with Bott-Morse theoretic techniques we provide an exact component count for moduli spaces of maximal parabolic Sp(2n, R)-Higgs bundles with fixed parabolic structure.

1. INTRODUCTION

Let X be a smooth, irreducible, projective curve of genus g ≥ 2 over C and let η ∈ A = ⊕ i=1 H0(X, Ki), where K denotes the canonical line bundle over X. The Beauville-Narasimhan-Ramanan correspondence (Proposition 3.6 in [2]) in its simplest form provides a bijective correspondence between isomorphism classes of twisted Higgs bundles over X and line bundles over the spectral curve Xη, defined by the point η ∈ A. Under this correspondence, fibers of the Hitchin fibration are Jacobians of Xη.

Considering a set D = {x1, ..., xs} of finitely many points on X, a version of the correspondence for parabolic Higgs bundles with Higgs fields having (possibly) irregular singularities at the points in D was proven by S. Szabó in [20]. On the other hand, for local systems on a smooth Deligne-Mumford stack, the Beauville-Narasimhan-Ramanan correspondence provides the existence of a canonical morphism from the stack of flat connections M_{dR} to the Frobenius twist A(1), called the twisted Hitchin morphism (see [12]).

In this article, the focus is on parabolic Higgs bundles with regular (tame) singularities and we prove the following version of this correspondence:

**Proposition.** 5.2 Fix a parabolic structure α for a rank n parabolic bundle over X and a tuple of sections η = (ηi), where ηi is a section of K(D)i for 1 ≤ i ≤ n. Assume that the surface Xη is nonsingular and the intersection of the branch points B and the given divisor D is empty. For a fixed order for the preimage π−1(x) = {x1, ..., xn} of each x ∈ D, then there is a bijective correspondence between isomorphism classes of strictly compatible parabolic line bundles (L, α) on Xη and isomorphism classes of pairs (E, Φ), where E is a parabolic bundle of rank n with parabolic structure α and Φ : E → E ⊗ K(D) a parabolic Higgs field with characteristic coefficients ηi.

In the case when the weights in the parabolic structure are rational numbers, there is a bijection between moduli of semistable parabolic Higgs bundles over X and semistable Higgs bundles over an orbifold M (called a V-surface) with underlying manifold the Riemann surface X. In the construction of the orbifold surface the denominator of the weights is describing the cyclic group action around the marked points of D (see [7], [10], [18] for the detailed construction). For our purposes, we provide here an L-twisted version of this correspondence (Proposition 5.4), for L a line V-bundle over M. Let η = (ηi) ∈ A be a set of sections of L', for 1 ≤ i ≤ n. We construct a spectral covering π : Mη → M of a V-surface M by pulling back the spectral cover Xη → X and defining an atlas for the V-surface Mη over (Xη, π−1 (D)). The following corollary is then implied from this version of the correspondence:

**Corollary.** 5.7 Assume that the underlying surface of Mη is nonsingular and the intersection of the set of branch points B and the divisor D is empty. Then there is a bijective correspondence
between isomorphism classes of strictly compatible line $V$-bundles $L$ on $M_{\eta}$ and isomorphism classes of pairs $(E, \Phi)$, where $E$ is a $V$-bundle of rank $n$ over $M$ and $\Phi : E \to E \otimes L$ a homomorphism with characteristic coefficients $\eta_i$. For $\rho : M_{\eta} \to M$, it is $\rho_*(L) = E$.

In order to provide a complete description of the Beauville-Narasimhan-Ramanan correspondence and the correspondence among parabolic Higgs bundles, Higgs $V$-bundles and Higgs bundles over a root stack, we have one-to-one correspondences between the following six categories:

- $\mathcal{L}$-twisted Higgs $V$-bundles over $M$
- line $V$-bundles over $M_{\eta}$
- parabolic $\mathcal{L}$-twisted Higgs bundles
- parabolic line bundles over $X_{\eta}$
- $\mathcal{L}$-twisted Higgs bundles over stack $X$
- line bundles over $X_{\eta}$

The fiber of the parabolic Hitchin map

$$\mathcal{M}_{par}(X, D, n, m) \to \bigoplus_i H^0(X, K(D)^i)$$

over a regular point $\eta \in \bigoplus_i H^0(X, K(D)^i)$ is isomorphic to the $V$-Picard group of the spectral covering $M_{\eta}$ of $M$, where $M$ is uniquely determined by the data $(X, D, m)$.

In the special case of parabolic Higgs bundles with rank 2 and rational weights with denominator 2, the parabolic Hitchin fibration of a regular point $\eta \in H^0(X, K(D)^2)$ is precisely the Prym variety

$$\text{Prym}(M_{\eta}, M) = \{ L \in \text{Pic}_V(M_{\eta}) | \tau^* L = L^{-1} \}$$

of the spectral covering $M_{\eta} \to M$, where $M$ and $M_{\eta}$ are the corresponding $V$-surfaces of $X$ and $X_{\eta}$, and $\tau : M_{\eta} \to M_{\eta}$ is the involution of $M_{\eta}$. Namely, we show:

**Proposition 5.10** The fiber of the parabolic Hitchin map

$$\mathcal{M}_{par}(X, D, 2, 2) \to H^0(X, K(D)^2)$$

is a finite number of copies of the Prym variety $\text{Prym}(M_{\eta}, M)$. This number of copies only depends on the parabolic structure $\alpha$.

We next focus on the problem of providing an exact component count for moduli spaces of maximal parabolic $Sp(2n, \mathbb{R})$-Higgs bundles $(E, \Phi)$ over $(X, D)$. In this direction, we employ Bott-Morse theoretic techniques, first developed for parabolic Higgs bundles in [6], [8] to study spaces of minima of the positive functional

$$f ([(E, \Phi)]) = \frac{1}{2} \| \Phi \|^2$$
This map is non-negative and proper, thus a subspace $N$ of this moduli space is connected, if the subspace of local minima of $f$ in $N$ is. The subspaces of local minima coincide with the critical subvarieties, thus correspond to variations of Hodge structures. We compute the Morse indices of $f$ and show that particular subvarieties of the moduli space defined by appropriate topological invariants are connected. The method is parallel to the non-parabolic version studied by P. Gothen in [11]. We prove accordingly:

**Theorem.** 7.7 The moduli space $\mathcal{M}_{\text{par}}^{\text{max}}(\text{Sp}(4, \mathbb{R}))$ of parabolic maximal $\text{Sp}(4, \mathbb{R})$-Higgs bundles with all weights rational having denominator 2 over a compact Riemann surface $X$ of genus $g$ with a divisor of $s$-many distinct points on $X$, such that $2g - 2 + s > 0$, has $(2^s + 1)2^{2g+s-1} + (2g - 3 + s)2^s$ many connected components.

**Theorem.** 7.8 For $n \geq 3$, the moduli space $\mathcal{M}_{\text{par}}^{\text{max}}(\text{Sp}(2n, \mathbb{R}))$ of parabolic maximal $\text{Sp}(2n, \mathbb{R})$-Higgs bundles with all weights rational having denominator 2 over a compact Riemann surface $X$ of genus $g$ with a divisor of $s$-many distinct points on $X$, such that $2g - 2 + s > 0$, has $(2^s + 1)2^{2g+s-1}$ many connected components.

For points $(V, \beta, \gamma)$ in the moduli space $\mathcal{M}_{\text{par}}^{\text{max}}(\text{Sp}(2n, \mathbb{R}))$ for any $n \geq 2$, we further fix the parabolic structure on the parabolic bundle $V$ and study the connected component count problem for different values of rational weights. Among other results, we verify the prediction made in [16] on the number of components when the flag $\alpha$ on $V$ is trivial with weight $\frac{1}{2}$:

**Corollary.** 8.1 The number of connected components of the moduli space $\mathcal{M}_{\text{par}}^{\text{max}}(\text{Sp}(4, \mathbb{R}), \alpha)$ with fixed trivial filtration and weight $\frac{1}{2}$ is

$$(2^s + 1)2^{2g+s-1} + (2g - 2 + s) - 2^s.$$ 

In the final section of this paper, we generalize our approach to count the connected components of $\mathcal{M}_{\text{par},(m_1,...,m_s)}^{\text{max}}(\text{Sp}(2n, \mathbb{R}))$, where $\mathcal{M}_{\text{par},(m_1,...,m_s)}^{\text{max}}(\text{Sp}(2n, \mathbb{R}))$ denotes the moduli space of polystable maximal $\text{Sp}(2n, \mathbb{R})$-Higgs bundles with weight type of $(m_i)_{1 \leq i \leq s}$; by the latter, we mean that the weight $\alpha$ at each point $x_i \in D$ in the parabolic structure of the bundle is an integral multiple of $\frac{1}{m_i}$ for $1 \leq i \leq s$ and $1 \leq j \leq n$. When $m_1 = \cdots = m_s = 2$, $\mathcal{M}_{\text{par},(2,...,2)}^{\text{max}}(\text{Sp}(2n, \mathbb{R}))$ is exactly the moduli space $\mathcal{M}_{\text{par}}^{\text{max}}(\text{Sp}(2n, \mathbb{R}))$ considered above for $n \geq 2$. The following results describe a count of the number of connected components:

**Theorem.** 9.3 Let $X$ be a compact Riemann surface of genus $g$ with a divisor $D$ of $s$-many distinct points on $X$, such that $2g - 2 + s > 0$. Then, the moduli space of polystable maximal parabolic $\text{Sp}(4, \mathbb{R})$-Higgs bundles on $(X, D)$ with weight type $(m_i)_{1 \leq i \leq s}$ has

$$(2^{s_0} + 1)2^{2g+s_0-1} - 2^{s_0} + (2g - 2 + s) \prod_{i=1}^{s} m_i$$

connected components, where $s_0$ is the number of the even $m_i$ in the collection $(m_i)_{1 \leq i \leq s}$.

**Theorem.** 9.4 Let $X$ be a compact Riemann surface of genus $g$ with a divisor $D$ of $s$-many distinct points on $X$, such that $2g - 2 + s > 0$. Then, the moduli space of polystable maximal parabolic $\text{Sp}(2n, \mathbb{R})$-Higgs bundles $(n \geq 3)$ on $(X, D)$ with weight type $(m_i)_{1 \leq i \leq s}$ has

$$(2^{s_0} + 1)2^{2g+s_0-1}$$

connected components, where $s_0$ is the number of the even $m_i$ in the collection $(m_i)_{1 \leq i \leq s}$.

Let $\alpha_{ij} = \frac{k_{ij}}{m_i}$ be the weights over the puncture $x_i \in D$ with the same denominator $m_i$, where $k_{ij}$ is a positive integer, for $1 \leq i \leq s$ and $1 \leq j \leq n$. We call the parabolic structure $\alpha$ irreducible, if there is at least one enumerator $k_{ij}$ such that $k_{ij}$ and $m_i$ are coprime, for any $1 \leq i \leq s$. Using the same arguments as in the preceding two theorems, we finally obtain:
Corollary. 9.5 Let $X$ be a compact Riemann surface of genus $g$ with a divisor $D$ of $s$-many distinct points on $X$, such that $2g - 2 + s > 0$. Then, the moduli space of polystable maximal parabolic $Sp(4,\mathbb{R})$-Higgs bundles on $(X, D)$ with any irreducible parabolic structure $\alpha$ has 

$$(2^{s_0} + 1)2^{2s + s_0 - 1} - 2^{s_0} + (2g - 2 + s)$$

connected components, where $s_0$ is the number of the even $m_i$ in the collection $(m_i)_{1 \leq i \leq s}$.

2. PARABOLIC $Sp(2n,\mathbb{R})$-HIGGS BUNDLES AND THEIR MODULI

In this section, we review basic facts about moduli spaces of parabolic Higgs bundles and set up notation.

2.1. Parabolic vector bundles. Let $X$ be a closed, connected, smooth Riemann surface of non-negative genus $g$ together with a finite collection of distinct points $x_1, \ldots, x_s$. Denote by $D$ the effective divisor

$$D = x_1 + \ldots + x_s$$

with $x_i \neq x_j$, for $i \neq j$. The pair $(X, D)$ will be kept fixed throughout.

**Definition 2.1.** A parabolic vector bundle $E$ of rank $n$ over $(X, D)$ is a holomorphic vector bundle together with a parabolic structure along $D$, that is, a collection of weighted flags on each fiber $E_x$ for $x \in D$:

$$E_x = E_{x,1} \supset E_{x,2} \supset \ldots \supset E_{x,r(x)+1} = \{0\}$$

$$0 \leq \alpha_1(x) < \ldots < \alpha_{r(x)}(x) < 1$$

where $r(x)$ is an integer between $1$ and $n$.

The real numbers $\alpha_i(x) \in [0, 1)$ for $1 \leq i \leq r(x)$ are called the weights of the subspaces $E_x$ and we usually write $(E, \alpha)$ to denote a parabolic vector bundle equipped with a parabolic structure determined by a system of weights $\alpha(x) = (\alpha_1(x), \ldots, \alpha_{r(x)}(x))$ at each $x \in D$; whenever the system of weights is not discussed in the context, we will be omitting the notation $\alpha$ to ease exposition. Moreover, let $k_i(x) = \dim (E_{x,i}/E_{x,i+1})$ denote the multiplicity of the weight $\alpha_i(x)$ and notice that $\sum_i k_i(x) = n$. A weighted flag shall be called full, if $k_i(x) = 1$ for every $1 \leq i \leq r(x)$ and every $x \in D$.

We define parabolic degree and parabolic slope of a parabolic vector bundle over $(X, D)$ as follows

$$\text{par deg} (E) = \deg E + \sum_{x \in D} \sum_{i=1}^{r(x)} k_i(x) \alpha_i(x)$$

$$\text{par} \mu (E) = \frac{\text{par deg} (E)}{rk(E)}$$

In the sequel, we will be making frequent use of the notion of subbundle, dual, direct sum and tensor product of parabolic vector bundles. We review these constructions below:

**Parabolic subbundle.** Let $(E, \alpha)$ be a parabolic vector bundle over $(X, D)$. A parabolic subbundle $(V, \beta)$ of $(E, \alpha)$ is described by a holomorphic vector subbundle $V \subseteq E$ together with a parabolic structure along the divisor $D$ given by the flag

$$V_x = V_{x,1} \supset V_{x,2} \supset \ldots \supset V_{x,r(x)+1} = \{0\}$$

for $V_{x,i} = V_x \cap E_{x,i}$, and a system of weights $\beta(x) = (\beta_1(x), \ldots, \beta_{r(x)}(x))$ defined by

$$\beta_i(x) = \max_j \{ \alpha_j(x) | V_x \cap E_{x,j} = V_{x,i} \}$$

$$= \max_j \{ \alpha_j(x) | V_{x,i} \subseteq E_{x,j} \}$$

In other words, the weight for $V_{x,i}$ is the weight $\alpha_j(x)$ for which $V_{x,i} \subseteq E_{x,j}$ but $V_{x,i} \nsubseteq E_{x,j+1}$. 
Parabolic dual. Let \((E, \alpha)\) be a parabolic vector bundle over \((X, D)\). Consider the following filtration for each point \(x \in D\):
\[
E^\vee_x = E^\vee_{x,1} \supset \cdots \supset E^\vee_{x,r(x)} \supset 0
\]
\[
1 - \alpha_{r(x)}(x) < \cdots < 1 - \alpha_1(x)
\]
where \(E^\vee_{x,i} := \text{Hom}(E_x/E_{x,r(x)+1}, \mathcal{O}(-D)_x)\). It is easy to check that
\[
(E^\vee)^\vee = E \quad \text{and} \quad \text{par deg}(E^\vee) = -\text{par deg}(E).
\]
We call \(E^\vee\) the parabolic dual of \(E\).

Parabolic direct sum. Let \((E, \alpha)\) and \((E', \alpha')\) be two parabolic vector bundles over the pair \((X, D)\). Their parabolic direct sum \(\left(\tilde{E}, \tilde{\alpha}\right)\) is defined as the holomorphic vector bundle \(\tilde{E} := E \oplus E'\) together with a system of weights \(\tilde{\alpha}\) comprised of the ordered collection of the weights in \(\alpha\) and \(\alpha'\) corresponding to the filtration of \(\tilde{E}_{x,k} = E_{x,i} \oplus E'_{x,j}\), where \(i\) (resp. \(j\)) is the smallest integer such that \(\tilde{\alpha}_k(x) \leq \alpha_i(x)\) (resp. \(\tilde{\alpha}_k(x) \leq \alpha'_j(x)\)). Under this definition the parabolic degree now satisfies the relation
\[
\text{par deg}(E \oplus E') = \text{par deg}(E) + \text{par deg}(E').
\]

Parabolic tensor product. Let now \((E, \alpha)\) be a parabolic vector bundle and \((L, \beta)\) be a parabolic line bundle over \((X, D)\). Notice that \(L\) is a locally free sheaf of rank 1, thus the filtration of \(L\) at a point \(x \in D\) is always given by the trivial flag \(L_x \supset 0\) with weight \(\beta(x)\) for this filtration. The parabolic tensor product \(E \otimes L\) is defined as the kernel of the following map
\[
E \otimes L(D) \rightarrow \bigoplus_{x \in D} \left( (E_x/E_{x,i_x}) \otimes L(D)_x \right),
\]
where \(i_x = \min\{r(x) + 1, i(\alpha_i(x) + \beta(x) \geq 1)\}\), for \(x \in D\). The filtration is given by
\[
E_{x,i_x} \otimes L(D)_x \supset \cdots \supset E_{x,r(x)} \otimes L(D)_x \supset E_{x,1} \otimes L_x \supset \cdots \supset E_{x,i_x-1} \otimes L_x
\]
with weights
\[
\alpha_{i_x}(x) + \beta(x) - 1 < \cdots < \alpha_{r(x)}(x) + \beta(x) - 1 < \alpha_1(x) + \beta(x) < \cdots < \alpha_{i_x}(x) - 1 + \beta(x).
\]
This construction can be extended to vector bundles or locally free sheaves of any rank; details can be found in [22]. The parabolic tensor product of two parabolic vector bundles \(E\) and \(F\) now satisfies
\[
\text{par deg}(E \otimes F) = \text{rk}(F)\text{par deg}(E) + \text{rk}(E)\text{par deg}(F).
\]

**Definition 2.2.** For a pair of parabolic vector bundles \((E, \alpha), (E', \alpha')\) over the pair \((X, D)\) a holomorphic map \(f : E \rightarrow E'\) is called parabolic if \(\alpha_i(x) > \alpha'_j(x)\) implies \(f(E_{x,i}) \subset E'_{x,j+1}\) for every \(x \in D\). Furthermore, we call such map strongly parabolic if \(\alpha_i(x) \geq \alpha'_j(x)\) implies \(f(E_{x,i}) \subset E'_{x,j+1}\) for every \(x \in D\).

**Definition 2.3.** A parabolic vector bundle \((E, \alpha)\) over \((X, D)\) will be called stable (resp. semistable), if for every non-trivial proper parabolic subbundle \(V \leq E\) it is \(\text{par}_\mu(V) < \text{par}_\mu(E)\) (resp. \(\leq\)). A parabolic vector bundle is called poly-stable, if it is a direct sum of stable parabolic vector bundles of the same parabolic slope.

2.2. Moduli of parabolic Higgs bundles.

**Definition 2.4.** Let \((X, D)\) be a pair of a Riemann surface together with a divisor. Denote by \(K = \Omega^1_X\) the canonical line bundle over \(X\) and consider \(K(D) := K \otimes \mathcal{O}_X(D)\). A (strongly) parabolic Higgs bundle \((E, \Phi)\) is a pair of a parabolic vector bundle \(E\) and a (strongly) parabolic morphism \(\Phi : E \rightarrow E \otimes K(D)\) called a Higgs field.

**Remark 2.5.** For a strongly parabolic Higgs bundle \((E, \Phi)\) the Higgs field \(\Phi\) is a meromorphic endomorphism valued 1-form with at most simple poles along the divisor \(D\) and with Res\(_x\) \(\Phi\) nilpotent for each \(x \in D\). In other words, it is satisfied that \(\Phi(E_{x,i}) \subset E_{x,i+1} \otimes K(D)_x\) for every \(x \in D\).
Definition 2.6. A (strongly) parabolic Higgs bundle \((E, \Phi)\) will be called stable (resp. semistable), if for every non-trivial \(\Phi\)-invariant parabolic subbundle \(V \subseteq E\), it holds that \(\text{par}(V) < \text{par}(V)\) (resp. \(\leq\)); by \(\Phi\)-invariant it is meant here that \(\Phi(V) \subseteq V \otimes K(D)\).

For a given rank \(n\) and a given parabolic structure \(\alpha\) on the underlying parabolic vector bundle \(E\), a moduli space of semistable parabolic Higgs bundles \((E, \Phi)\) over \((X, D)\) was constructed by K. Yokogawa as a complex quasi-projective variety, which is smooth at the stable points (see [21], [22]). We prefer to consider the poly-stable objects in this moduli space. Let \(\mathcal{M}_{\text{par}}(X, D, \alpha, n)\) denote the moduli space of rank \(n\) poly-stable parabolic Higgs bundles over \((X, D)\) with parabolic structure \(\alpha\).

In this article, we wish to restrict to smaller moduli spaces than \(\mathcal{M}_{\text{par}}(X, D, \alpha, n)\). For a positive integer \(m \geq 2\), denote by \(\mathcal{M}_{\text{par}}(X, D, \alpha, n, m)\) the moduli space of parabolic Higgs bundles \((E, \Phi)\) such that the weights in the system \(\alpha\) can be written as rational numbers with denominator \(m\). Clearly,

\[
\mathcal{M}_{\text{par}}(X, D, \alpha, n) \subset \mathcal{M}_{\text{par}}(X, D, \alpha, n, m).
\]

Similarly, denote by \(\mathcal{M}_{\text{par}}(X, D, n)\) the moduli space of rank \(n\) poly-stable parabolic Higgs bundles \((E, \Phi)\) with arbitrary parabolic structure, and \(\mathcal{M}_{\text{par}}(X, D, n, m)\) the moduli space of rank \(n\) poly-stable parabolic Higgs bundles \((E, \Phi)\) equipped with a parabolic structure in which the weights can be written as rational numbers with denominator \(m\).

2.3. Parabolic \(\text{Sp}(2n, \mathbb{R})\)-Higgs bundles. In the sequel, we shall be considering parabolic Higgs bundles for structure group \(G = \text{Sp}(2n, \mathbb{R})\). A general theory of parabolic \(G\)-Higgs bundles for a real reductive group \(G\) was carried out in [3], where a Hitchin-Kobayashi correspondence was also established. For our purposes, we will consider here parabolic \(\text{Sp}(2n, \mathbb{R})\)-Higgs bundles as special parabolic Higgs bundles \((E, \Phi)\); one can check though that the general definition from [3] specializes when \(G = \text{Sp}(2n, \mathbb{R})\) to the definition we describe next.

Let \((X, D)\) and \(K(D)\) as defined in §2.1 and §2.2. A maximal compact subgroup of \(G = \text{Sp}(2n, \mathbb{R})\) is \(H \cong \text{U}(n)\) and \(H^\mathbb{C} = \text{GL}(n, \mathbb{C})\), thus the parabolic structure is defined on a \(\text{GL}(n, \mathbb{C})\)-principal bundle.

Definition 2.7. A parabolic \(\text{Sp}(2n, \mathbb{R})\)-Higgs bundle over \((X, D)\) is defined as a triple \((V, \beta, \gamma)\), where

- \(V\) is a holomorphic rank \(n\) parabolic bundle on \(X\) such that all of the weights have denominator 2.
- The maps \(\beta : V^\vee \rightarrow V \otimes K(D)\) and \(\gamma : V \rightarrow V^\vee \otimes K(D)\) are symmetric parabolic morphisms.

The parabolic structures on \(V\) and \(V^\vee\) now induce a parabolic structure on the parabolic direct sum \(E = V \oplus V^\vee\), for which \(\text{par deg} E = 0\). The definition of a parabolic \(\text{Sp}(2n, \mathbb{R})\)-Higgs bundle on \((X, D)\) is now reinterpretated as a pair \((E, \Phi)\) such that

\[
E = V \oplus V^\vee, \quad \Phi = \begin{pmatrix} 0 & \beta \\ \gamma & 0 \end{pmatrix} : E \rightarrow E \otimes K(D).
\]

The stability condition for such pairs \((E, \Phi)\) is given in Definition 2.6. In the rest of the paper, we shall denote by \(\mathcal{M}_{\text{par}}(\text{Sp}(2n, \mathbb{R}))\) the moduli space of the triples \((V, \beta, \gamma)\) defined above. Note that in Definition 2.7 the weights of the parabolic structure for \(V\) have denominator 2. Therefore, for us

\[
\mathcal{M}_{\text{par}}(\text{Sp}(2n, \mathbb{R})) = \mathcal{M}_{\text{par}}(X, D, n, 2),
\]

in the notation of §2.2.

Now we consider a special parabolic structure. Let \(V\) be a holomorphic rank \(m\) vector bundle defined over the compact Riemann surface \(X\). We fix a parabolic structure on \(V\) as follows. The parabolic structure is defined by a trivial flag \(V_x \supset \{0\}\) and weight \(\frac{1}{2}\) for each \(V_x\) and \(x \in D\). Then the parabolic symmetric power \(\text{Sym}^m(V)\) is equipped with the trivial flag and weight \(\frac{1}{2}\). Denote by \(V^\vee\) the parabolic dual of \(V\), which is defined as \((V^*) \otimes \mathcal{O}_X(D)^*\). The parabolic symmetric power for the parabolic dual \(\text{Sym}^m(V^\vee)\) is defined as the symmetric product of the bundle \((V^*) \otimes \mathcal{O}_X(D)^*\) equipped
with a parabolic structure given by the trivial flag and weight $\frac{1}{2}$. Denote this parabolic structure by $\hat{\alpha}$, and define
\[ \mathcal{M}_{\text{par}}(\text{Sp}(2n, \mathbb{R}), \hat{\alpha}) := \mathcal{M}_{\text{par}}(X, D, \hat{\alpha}, n, 2). \]
We will compute the number of connected components of this moduli space (with maximal parabolic degree) in §8.

**Remark 2.8.** In the definition of a parabolic $\text{Sp}(2n, \mathbb{R})$-Higgs bundle we could have considered any parabolic flag on the fiber $V_{x_i}$:
\[ V_{x_i} \supset V_{x_i,2} \supset \ldots \supset V_{x_i,n+1} = \{0\} \]
for each $x_i \in D$. The reason for fixing the trivial flag with weight $\frac{1}{2}$ will become clear later on in §3, where we use the data $(X, D, m = 2)$ in order to construct the corresponding $V$-surface $M$ and use the topological invariants of Higgs $V$-bundles to study the topology of the moduli space of parabolic Higgs bundles. These invariants will be defined as characteristic classes in $V$-cohomology groups with $\mathbb{Z}_2$-coefficients.

### 3. Bott-Morse Theory on $\mathcal{M}_{\text{par}}(\text{Sp}(2n, \mathbb{R}))$

Bott-Morse theoretic techniques for the study of moduli spaces of parabolic Higgs bundles were developed in [6], [8] and have been applied in the case of the moduli space of parabolic $U(p, q)$-Higgs bundles in [9]. Similar to the non-parabolic case, there is a natural $\mathbb{C}^*$-action on the moduli space $\mathcal{M}_{\text{par}}(\text{Sp}(2n, \mathbb{R}))$ given by the map $\lambda \cdot (E, \Phi) = (E, \lambda \Phi)$. For finding solutions to the Hitchin equations, we restrict the action to $S^1 \subset \mathbb{C}^*$. With respect to the complex structure studied by H. Konno [15], this is a Hamiltonian action and the associated moment map is
\[ [(E, \Phi)] \rightarrow -\frac{1}{2} \| \Phi \|^2 = -i \int_X \text{Tr}(\Phi \Phi^*) . \]
We choose instead to consider the positive function
\[ f([(E, \Phi)]) = \frac{1}{2} \| \Phi \|^2 . \]
The map $f$ is non-negative and proper [4], as follows from the properness of the moment map associated to the circle action on $\mathcal{M}_{\text{par}}(\text{Sp}(2n, \mathbb{R}))$. Thus, a subspace $\mathcal{N}$ of $\mathcal{M}_{\text{par}}(\text{Sp}(2n, \mathbb{R}))$ is connected if the subspace of local minima of $f$ in $\mathcal{N}$ is connected. To find the local minima of $f$, we must first determine the critical points of $f$. The following theorem indicates that critical points of $f$ are exactly the fixed points under the circle action $S^1$ on $\mathcal{M}_{\text{par}}(\text{Sp}(2n, \mathbb{R}))$.

**Proposition 3.1** (Proposition 3.3 in [8]). The proper map $f$ is a prefect Bott-Morse function. The critical points of $f$ are exactly the fixed points of the circle action. Moreover, the eigenvalue $1$ subspace for the Hessian of $f$ is the same as the weight $-1$ subspace for the infinitesimal circle action on the tangent space. In particular, the Morse index of $f$ at a critical point equals the dimension of the positive weight space of the circle action on the tangent space.

#### 3.1. The deformation complex.

In [16], §3, we studied the deformation theory for parabolic G-Higgs bundles, when $G$ is a semisimple reductive Lie group. For $H \subset G$ a maximal compact subgroup and $\mathfrak{g} = \mathfrak{h} \oplus \mathfrak{m}$ a Cartan decomposition of the Lie algebra, the deformation complex of a parabolic $G$-Higgs bundle $(E, \Phi)$ over $(X, D)$ is defined as the complex of sheaves
\[ C^\bullet(E, \Phi) : E(\mathfrak{h}^C) \rightarrow E(\mathfrak{m}^C) \otimes K(D) . \]
Moreover, the space of infinitesimal deformations of a $G$-Higgs bundle $(E, \Phi)$ is naturally isomorphic to the hypercohomology group $\mathbb{H}^1(C^\bullet(E, \Phi))$. Now, an element $(E, \Phi)$ is a fixed point if and only if there is an infinitesimal gauge transformation $\psi \in H^0(X, E(\mathfrak{g}^C) \otimes K(D))$ such that
\[ d_E \psi = 0, \quad [\psi, \Phi] = i \Phi . \]
Then, \((E, \Phi)\) can be decomposed as the direct sum of eigenspaces of the gauge transformation \(\psi\). We have
\[
E(g^C) = \oplus U_m,
\]
where \(\psi|_{U_m} = im\). By the relation \([\psi, \Phi] = i\Phi\), we have \(\Phi : U_m \to U_{m+1} \otimes K(D)\), thus \(\Phi \in H^0(X, \mathbb{U}_1 \otimes K(D))\). However, since \(E(g^C) \cong E(h^C) \oplus E(m^C)\), and \(\Phi \in H^0(X, E(m^C) \otimes K(D))\), we conclude that \(\text{ad}\Phi\) interchanges \(E(h^C)\) and \(E(m^C)\), whereas
\[
E(h^C) = \oplus U_{2m}, \quad E(m^C) = \oplus U_{2m+1}.
\]

The following observation is made by N. Hitchin [13] in the non-parabolic case, while the parabolic version can be found in [8]. If \(\psi\) acts with weight \(m\) on an element in \(E(g^C) = \oplus U_m\), then the corresponding eigenvalue of the Hessian of \(f\) is \(-m\), while a weight \(m\) on \(E(g^C) \otimes K(D)\) gives the eigenvalue \(1 - m\). Let \(C^* (E, \Phi)_-\) be the restriction of the complex \(C^* (E, \Phi)\) to the positive weight part. The Hessian of \(f\) is negative definite on \(\mathbb{H}^1(C^* (E, \Phi)_-)\). The positive part of the complex can be written as
\[
C^* (E, \Phi)_- : \bigoplus_{m \geq 1} U_{2m} \xrightarrow{\text{ad}\Phi} \bigoplus_{m \geq 1} U_{2m+1} \otimes K(D).
\]

The next lemma will be very important in describing the connected components of \(\mathcal{M}_{\text{par}}(\text{Sp}(2n, \mathbb{R}))\). It is implied from §3 in [8], similarly to the classical case of non-parabolic Higgs bundles [11].

**Lemma 3.2.** The poly-stable Higgs bundle \((E, \Phi)\) represents a local minimum of \(f\) if and only if \(\dim \mathbb{H}^1(C^* (E, \Phi)_-) = 0\).

### 3.2. Local minima of \(f\)
We describe polystable parabolic \(\text{Sp}(2n, \mathbb{R})\)-Higgs bundles \((E, \Phi)\) representing local minima of the Hitchin functional \(f : \mathcal{M}_{\text{par}}(\text{Sp}(2n, \mathbb{R})) \to \mathbb{R}\) as defined earlier. The treatment is parallel to that by P. Gothen in the non-parabolic case [11].

**Proposition 3.3.** Let \((V, \beta, \gamma)\) be a poly-stable \(\text{Sp}(4, \mathbb{R})\)-Higgs bundle. \((V, \beta, \gamma)\) represents a local minimum of the parabolic Hitchin function if and only if one of the following holds

1. If \(\text{pardeg } V > 0\), then \(\beta = 0\).
2. If \(\text{pardeg } V = 2g - 2 + s\), we have a decomposition \(V = L_1 \oplus L_2\), and \(\beta = \begin{pmatrix} 0 & 0 \\ 0 & b \end{pmatrix}\), \(\gamma = \begin{pmatrix} 0 & c_1 \\ c_2 & 0 \end{pmatrix}\).

**Proof.** As we discussed, if \((E, \Phi)\) is a local minimum, then \(E(g^C) = \oplus U_m\) can be written as the direct sum of stable Higgs bundles \(U_m\) with respect to \(\psi \in H^0(X, E(g^C) \otimes K(D))\). Since we consider the Lie algebra \(g = \mathfrak{sp}(4, \mathbb{R})\), and the complexification of \(h\) appearing in the Cartan decomposition \(g = h \oplus m\) is \(h^C = \mathfrak{u}(2)\), thus for \(\text{deg } V \geq 0\) there are only the following two possibilities

(a) \(E = F_{-\frac{1}{2}} \oplus F_{\frac{1}{2}}, V = F_{-\frac{1}{2}}, V^\vee = F_{\frac{1}{2}}\)

(b) \(E = F_{-\frac{1}{2}} \oplus F_{\frac{1}{2}} \oplus F_{\frac{1}{2}} \oplus F_{\frac{3}{2}}, V = F_{-\frac{1}{2}} \oplus F_{\frac{1}{2}}, V^\vee = F_{\frac{3}{2}} \oplus F_{-\frac{1}{2}}\).

In Case (a), we have \(V = F_{-\frac{1}{2}}\) and \(V^\vee = F_{\frac{1}{2}}\) with Higgs field \(\Phi : V \to V^\vee \otimes K(D)\). Thus the morphism \(b = 0\). This gives us case (1) of the proposition.

In Case (b), \(\Phi \in H^0(X, E(m^C))\) and there is a decomposition
\[
E = F_{-\frac{1}{2}} \oplus F_{-\frac{1}{2}} \oplus F_{\frac{1}{2}} \oplus F_{\frac{3}{2}}
\]
with the Higgs field \(\Phi = \begin{pmatrix} 0 & \beta \\ \gamma & 0 \end{pmatrix}\), where \(\beta = \begin{pmatrix} 0 & 0 \\ 0 & b \end{pmatrix}\), \(\gamma = \begin{pmatrix} 0 & c_1 \\ c_2 & 0 \end{pmatrix}\), for
\[
b : F_{-\frac{1}{2}} \to F_{\frac{1}{2}} \otimes K(D), \quad c_1 : F_{\frac{1}{2}} \to F_{\frac{1}{2}} \otimes K(D), \quad c_2 : F_{-\frac{1}{2}} \to F_{-\frac{1}{2}} \otimes K(D).
\]
Based on the decomposition of $E$, $E(g_0^C) = U_{-3} \oplus \ldots \oplus U_3$, where

$$U_2 = \text{Hom}(F_{-\frac{1}{2}}, F_{\frac{3}{2}}) \oplus \text{Hom}(F_{-\frac{3}{2}}, F_{\frac{1}{2}}),$$

$$U_3 = \text{Hom}(F_{-\frac{3}{2}}, F_{\frac{1}{2}}).$$

By Proposition 3.1, we only have to focus on the positive weight spaces $U_2$ and $U_3$. We have

$$\dim \mathbb{H}^1(C^*_G(E, \Phi)_-) = 2g - 2 + s + \text{par deg } F_{\frac{3}{2}} - \text{par deg } F_{-\frac{3}{2}} - (\text{par deg } F_{\frac{1}{2}} - \text{par deg } F_{-\frac{1}{2}})$$

$$= 2g - 2 + s - (\text{par deg } F_{-\frac{3}{2}} + \text{par deg } F_{\frac{1}{2}})$$

$$= 2g - 2 + s - \text{par deg } V,$$

where $C^*_G(E, \Phi)_-$ is the restriction of the complex $C^*_G(E, \Phi)$ to the positive weight part. By Lemma 3.2, we get a minimum if and only if $\text{par deg } V = 2g - 2 + s$. This proves that $(E, \Phi)$ is of Case (b) if and only if $\text{par deg } V = 2g - 2 + s$. This finishes the proof of the proposition. \hfill \Box

The proof of the local minimum condition in the $\text{Sp}(2n, \mathbb{R})$ case for $n \geq 3$ is similar to the above discussion. We only give the result without a proof.

**Proposition 3.4.** Let $(V, \beta, \gamma)$ be a poly-stable $\text{Sp}(2n, \mathbb{R})$-Higgs bundle for $n \geq 3$. $(V, \beta, \gamma)$ represents a local minimum of the Hitchin functional if and only if one of the following holds

1. If $\text{par deg } V > 0$, then $\beta = 0$.
2. If $\text{par deg } V = n(g - 1 + \frac{2}{n})$ and $m$ is odd, then there is a square root $L$ of the bundle $K(D)$ and a decomposition

$$V = LK(D)^{-2[\frac{n}{2}]} \oplus LK(D)^{-2[\frac{n}{2}]+2} \oplus \cdots \oplus LK(D)^{2[\frac{n}{2}]}.$$

With respect to this decomposition, the morphisms $\beta$ and $\gamma$ have the following form

$$\beta = \begin{pmatrix} 0 & \cdots & 1 & 0 \\ \vdots & \ddots & \vdots & \vdots \\ 1 & \cdots & 1 & 0 \end{pmatrix}, \quad \gamma = \begin{pmatrix} 0 & \cdots & 1 \\ \vdots & \ddots & \vdots & \vdots \\ 1 & \cdots & 0 \end{pmatrix},$$

where $\gamma$ is an anti-diagonal matrix.
3. If $\text{par deg } V = n(g - 1 + \frac{2}{n})$ and $n$ is even, there is a square root $L$ of the bundle $K(D)$ and a decomposition

$$V = L^{-1}K(D)^{2-n} \oplus L^{-1}K(D)^{4-n} \oplus \cdots \oplus L^{-1}K(D)^n.$$

With respect to this decomposition, the morphisms $\beta$ and $\gamma$ have the same form as in case (2) above.

4. **Parabolic Higgs Bundles vs. Higgs $V$-Bundles**

In this section we review the correspondence between parabolic Higgs bundles and Higgs $V$-bundles. Further details may be found in [16] and the references therein.

4.1. **Background and Correspondence.** Let $X$ be a $k$-dimensional manifold with $s$-many marked points $x_1, \ldots, x_s$. For each marked point, there is a linear representation $\sigma_i : \Gamma_i \rightarrow \text{Aut}(\mathbb{R}^k)$ of a cyclic group $\Gamma_i = \langle \sigma_i \rangle$, $1 \leq i \leq s$, where $\Gamma_i$ acts freely on $\mathbb{R}^k \setminus \{0\}$ together with an atlas of coordinate charts

$$\phi_i : U_i \rightarrow D^k / \sigma_i, \quad 1 \leq i \leq s;$$

$$\phi_p : U_p \rightarrow D^k,$$

$p \in X \setminus \{x_1, \ldots, x_s\}$. We assume that $\Gamma_i$ is the cyclic group $\mathbb{Z}_{m_i}$, where $m_i$ is a positive integer. An orbifold $M$ is obtained by gluing the local coordinate charts above, while $X$ is the underlying manifold of $M$. In [7], M. Furuta and B. Steer consider this construction as a $V$-manifold. The case we are interested in is when $M = [Y/\Gamma]$, where $Y$ is a closed, connected, smooth Riemann surface and $\Gamma$ is a finite group acting effectively on $Y$. In this case, we say that $M$ is a $V$-surface. From the definition of the $V$-manifold,
we see that the $V$-manifold is an orbifold, therefore we prefer to use the notation $[Y/\Gamma]$ to emphasize its $V$-manifold or orbifold structure. The notation $Y/\Gamma$ is the usual quotient. In this paper, $Y/\Gamma$ gives the underlying surface $X$ of $M$.

A holomorphic $V$-bundle $E$ of rank $n$ over $M$ is defined locally on the charts as above with a collection of isotropy representations $\tau_i : \Gamma_i \to Aut(C^n)$ and local trivializations $\theta_i : E|_{U_i} \to D^k \times C^n/\sigma_i \times \tau_i$, for $1 \leq i \leq s$. Let $m = m_i$ for all $i$. The local trivialization $\Theta$ is $\mathbb{Z}_m$-equivariant with respect to the action

$$ t(z; z_1, z_2, ..., z_n) = (tz; t^{k_1}z_1, t^{k_2}z_2, ..., t^{k_n}z_n), $$

We will define the $V$-Higgs field over the local chart $[U/\mathbb{Z}_m]$. The $V$-Higgs field defined on local charts can be glued naturally over the $V$-manifold $M$. We define $\Phi$ to be a Higgs field over the local chart $[U/\mathbb{Z}_m]$ as follows:

$$ \Phi = (\phi_{ij})_{1 \leq i,j \leq n}, $$

where

$$ \phi_{ij} = \begin{cases} 
  z^{k_i-k_j} \hat{\phi}_{ij}(z^m) \frac{dz}{z} & \text{if } k_i \geq k_j \\
  0 & \text{if } k_i < k_j,
\end{cases} $$

and $\hat{\phi}_{ij}$ are holomorphic functions on $\tilde{E}$.

**Definition 4.1.** A Higgs $V$-bundle over a $V$-surface $M$ is a pair $(E, \Phi)$, where $E$ is a holomorphic $V$-bundle and $\Phi$ is a $V$-Higgs field.

**Theorem 4.2 (Theorem 6.8 in [16]).** There is a bijective correspondence between isomorphism classes of holomorphic Higgs $V$-bundles with good trivialization $(E, \Theta, \Phi)$ and isomorphism classes of parabolic Higgs bundles $(F, \hat{\Theta}, \hat{\Phi})$.

**Remark 4.3.** In general, the $V$-Higgs field $\Phi = (\phi_{ij}) \in H^0(End_0(E) \otimes K)$ is $\mathbb{Z}_m$-equivariant, where $End_0(E)$ is the traceless homomorphism of $E$ and the action of $\mathbb{Z}_m$ on $End_0(E) \otimes K$ is conjugation. Under the conjugation action, we have

$$ \phi_{ij} = \begin{cases} 
  z^{k_i-k_j} \hat{\phi}_{ij}(z^m) \frac{dz}{z} & \text{if } k_i \geq k_j \\
  z^{k_i-k_j} \hat{\phi}_{ij}(z^m) \frac{dz}{z} & \text{if } k_i < k_j.
\end{cases} $$

Details can be found in [7]. In this paper, we slightly change the $V$-Higgs field and there are two reasons for doing so. The first reason is that if $k_i \leq k_j$, then $z^{k_i-k_j}$ possibly describes a meromorphic section, not holomorphic. The second reason is that if $\phi_{ij}$ is not trivial when $k_i < k_j$, then the corresponding Higgs field may not preserve the filtration.

Under this correspondence, we have

$$ \deg(E) = \par \deg(F). $$

In conclusion, the latter equality for the degree provides the correspondence of the moduli spaces:

**Proposition 4.4 (Proposition 5.9 in [7]).** There is a bijective correspondence between isomorphism classes of holomorphic semistable (resp. stable) $V$-Higgs bundles with good trivialization $(E, \Theta, \Phi)$ and isomorphism classes of semistable (resp. stable) parabolic Higgs bundles $(F, \hat{\Theta}, \hat{\Phi})$.

Indeed, we construct this special $V$-manifold from the data $(X, D, m = 2)$, where $X$ corresponds to the underlying surface, $D$ includes the punctures and $m = 2$ corresponds to the cyclic group action around the punctures. Therefore there is a one-to-one correspondence between the rank $n$ Higgs $V$-bundles over this special $V$-manifold and elements in $M_{par}(\text{Sp}(2n, \mathbb{R})) = M_{par}(X, D, n, 2)$ by Theorem 4.2. We use this correspondence to discuss the topological invariants of $\text{Sp}(2n, \mathbb{R})$-parabolic Higgs bundles over $(X, D)$ in §6.
4.2. **Line V-Bundle and V-Picard Group.** With the same notation as above, we have the following proposition about line V-bundles.

**Proposition 4.5 (Proposition 1.4 in [7])**. Isomorphism classes of line V-bundles on M with isotropy \( \sigma_1^{k_1}, \ldots, \sigma_s^{k_s} \) at \( x_1, \ldots, x_s \) are in bijective correspondence with the integers.

Proposition 4.5 gives us a general description about all line V-bundles over a V-surface \( M \). The degree of a line V-bundle \( L \) is given by the Riemann-Roch formula for line V-bundles over \( M \)

\[
\dim H^0(M, L) - \dim H^1(M, L) = 1 - g + c_1(L) - \sum_{i=1}^{s} \frac{k_i}{m_i},
\]

where \( c_1(L) \) is the degree for the line V-bundle \( L \). M. Furuta and B. Steer in [7] showed that tuples of the form \( (d, k_1, \ldots, k_s) \) classify the topological isomorphism classes of line V-bundles over \( M \), where \( d \) is an integer and \( 0 \leq k_i < m_i, 1 \leq i \leq s \). In other words, the tuple \( (d, k_1, \ldots, k_s) \) is a topological invariant for a line V-bundle \( L \). It is easy to check that the tensor product of line V-bundles is still a line V-bundle. Therefore, the collection of all line V-bundles has a natural group structure.

**Definition 4.6 (V-Picard Group).** Let \( \text{Pic}_V(M) \) denote the set (or group) of isomorphism classes of line V-bundles over \( M \).

**Corollary 4.7 (Corollary 1.6 in [7])**. We have a natural map

\[
\text{Pic}_V(M) \rightarrow \mathbb{Q} \oplus \left( \bigoplus_{i=1}^{s} \mathbb{Z}/m_i \right)
\]

\[
L \mapsto \left( c_1(L), \overline{k} \right),
\]

for \( \overline{k} = (k_1, \ldots, k_s) \) an injective homomorphism with image \( \{ c_1, (k_i \mod m_i) \} \), and where the first Chern class \( c_1 \equiv \sum \frac{k_i}{m_i} \mod \mathbb{Z} \).

In conclusion, Corollary 4.7 gives us the following exact sequence

\[
0 \rightarrow \text{Pic}(X) \rightarrow \text{Pic}_V(M) \rightarrow \bigoplus_{i=1}^{s} \mathbb{Z}/m_i \rightarrow 0.
\]

5. **The Beaville-Narasimhan-Ramanan Correspondence**

The Beaville-Narasimhan-Ramanan (BNR) correspondence (Proposition 3.6 in [2]) provides a very useful tool for studying the spectral curves constructed via the Hitchin fibration. It gives a one-to-one correspondence between the category of twisted Higgs bundles \( (E, \Phi) \) over a smooth Riemann surface and line bundles over the spectral curve. An application of the correspondence is that the regular Hitchin fiber is holomorphically equivalent to the Prym variety of the spectral covering (see [1], [2], [14]).

In this section, we study the BNR correspondence for twisted Higgs V-bundles and twisted parabolic Higgs bundles. We first fix notation. Let \( X \) be a Riemann surface, \( D = \{ x_1, \ldots, x_s \} \) a fixed set of \( s \)-many points on \( X \) and let \( m \) be a fixed positive integer. With respect to this integer \( m \), let \( M \) be the corresponding V-surface of \( X \) such that the local chart around \( x_i \) is isomorphic to \( \mathbb{C}/\mathbb{Z}_m \), where \( \mathbb{Z}_m \) the cyclic group. The V-surface \( M \) is uniquely determined by the data \( (X, D, m) \). In §4.1, we discussed a special case of this construction corresponding to \( (X, D, 2) \). Let \( L \) be a line V-bundle over \( M \), and \( L \) be the line bundle over \( X \) under the correspondence of Theorem 4.4.

5.1. **BNR Correspondence for Parabolic Higgs Bundles.** Let \( E \rightarrow X \) be a rank \( n \) parabolic vector bundle over \( X \). For each point \( x \in D \), we fix a weight tuple \( \alpha(x) = (\alpha_1(x), \ldots, \alpha_n(x)) \) such that \( 0 \leq \alpha_1(x) \leq \cdots \leq \alpha_n(x) < 1 \) and every \( \alpha_i(x) \) can be written as a fraction with denominator \( m \), \( 1 \leq i \leq n, x \in D \). Let \( \pi : \text{tot}(K(D)) \rightarrow X \) be the natural projection, where \( \text{tot}(K(D)) \) is the total
space of the line bundle. Denote by $\lambda$ the tautological section of $\pi^*K(D)$. Given $\eta = (\eta_i)$ a set of sections, where $\eta_i$ is a section of $K(D)^i$ for $1 \leq i \leq n$, we define $X_\eta$ as the zero set of the function

$$\lambda^n + \eta_1 \lambda^{n-1} + \eta_2 \lambda^{n-2} + \cdots + \eta_n.$$

We still denote by $\pi : X_\eta \to X$ the projection of the degree $n$ spectral covering. We also assume that the intersection of the set of branch points $B$ and the given divisor $D$ is empty.

**Definition 5.1.** A parabolic line bundle $(L, \tilde{\alpha})$ over $X_\eta$ is compatible with the given parabolic structure $\alpha$, if

$$\{\tilde{\alpha}(x), x \in \pi^{-1}(x)\} = \{\alpha_i(x), 1 \leq i \leq n\}.$$

Fix an order on the preimage $\pi^{-1}(x) = \{\tilde{x}_1, \ldots, \tilde{x}_n\}$ of each $x \in D$. A parabolic line bundle is strictly compatible with the given parabolic structure $\alpha$ and the given order of the preimage set, if

$$\tilde{\alpha}(\tilde{x}_i) = \alpha_i(x).$$

**Proposition 5.2.** Fix a parabolic structure $\alpha$ for a rank $n$ parabolic bundle over $X$ and a tuple of sections $\eta = (\eta_i)$, where $\eta_i$ is a section of $K(D)^i$ for $1 \leq i \leq n$. Assume that the surface $X_\eta$ is nonsingular and the intersection of the branch points $B$ and the given divisor $D$ is empty. For a fixed order for the preimage $\pi^{-1}(x) = \{\tilde{x}_1, \ldots, \tilde{x}_n\}$ of each $x \in D$, then there is a bijective correspondence between isomorphism classes of strictly compatible parabolic line bundles $(L, \tilde{\alpha})$ on $X_\eta$ and isomorphism classes of pairs $(E, \Phi)$, where $E$ is a parabolic bundle of rank $n$ with parabolic structure $\alpha$ and $\Phi : E \to E \otimes K(D)$ a parabolic Higgs field with characteristic coefficients $\eta_i$.

**Proof.** Let $E$ be a rank $n$ vector bundle over $X$ and $L$ the corresponding line bundle over $X_\eta$ under the classical BNR correspondence (Proposition 3.6 in [2]). Given $x \in D$, the parabolic structure over $x$ involves $n$-many rational numbers $\alpha_i(x)$, $1 \leq i \leq n$ corresponding to the weights. On the other hand, the preimage of $x$ contains $n$ points $\{\tilde{x}_1, \ldots, \tilde{x}_n\}$. Since $L$ is a line bundle, we can equip $L|_{\tilde{x}_i}$ with a parabolic structure given by

$$0 \leq L|_{\tilde{x}_i}, \quad 0 \leq \alpha_i(x).$$

This construction provides a parabolic structure $\tilde{\alpha}$ on $L$ such that $\tilde{\alpha}(\tilde{x}_i) = \alpha_i(x)$ and it is not hard to check that it is also a one-to-one correspondence for the parabolic structures.

**Remark 5.3.** If we do not fix an order for the preimage of $x \in D$ and only assume $L$ is compatible with the parabolic structure $\alpha$, then the correspondence may not be bijective. Assume $D$ only contains one point $x$. Consider two special cases:

(a) if $\alpha_i(x)$ are distinct rational numbers, then the correspondence is $n!$-to-one, which is the number of all possible orderings of the $n$ points in $\pi^{-1}(x)$;

(b) if $\alpha_i$ are all the same, then the correspondence is still one-to-one.

Now we consider the general case that we have $l$ distinct weights $\alpha_i(x), 1 \leq i \leq l$, and the weight $\alpha_i(x)$ appears $k_i$ times, $1 \leq i \leq l$. Then the correspondence is a $\binom{n}{k_1, \ldots, k_l}$-to-one correspondence.

The above correspondence can be easily extended to the case of $\mathbb{L}$-twisted parabolic Higgs bundles.

**Definition 5.4.** A pair $(E, \Phi)$ is an $\mathbb{L}$-twisted parabolic Higgs bundle over $(X, D)$, if $E$ is a parabolic Higgs bundle and $\Phi \in H^0(\text{End}(E) \otimes \mathbb{L})$ a holomorphic section preserving the filtration.

**Corollary 5.5.** Fix a parabolic structure $\alpha$ for a rank $n$ parabolic bundle over $X$ and a tuple of sections $\eta = (\eta_i)$, where $\eta_i$ is a section of $\mathbb{L}^i$ for $1 \leq i \leq n$. Assume that the surface $X_\eta$ is nonsingular and the intersection of the branch points $B$ and the given divisor $D$ is empty. For a fixed order for the preimage $\pi^{-1}(x) = \{\tilde{x}_1, \ldots, \tilde{x}_n\}$ of each $x \in D$, then there is a bijective correspondence between isomorphism classes of strictly compatible $\mathbb{L}$-twisted parabolic line bundles $(L, \tilde{\alpha})$ on $X_\eta$ and isomorphism classes of pairs $(E, \Phi)$, where $E$ is a parabolic bundle of rank $n$ with parabolic structure $\alpha$ and $\Phi : E \to E \otimes \mathbb{L}$ is an $\mathbb{L}$-twisted parabolic Higgs field with characteristic coefficients $\eta_i$. 

5.2. BNR Correspondence for $\mathcal{L}$-Twisted Higgs $V$-Bundle. To construct a version of the correspondence for $\mathcal{L}$-twisted Higgs $V$-bundles, we first generalize the correspondence between Higgs $V$-bundles and parabolic Higgs bundles described in §4 to the twisted case. Then, the BNR correspondence for the $\mathcal{L}$-twisted parabolic Higgs bundles directly provides a version for $\mathcal{L}$-twisted Higgs $V$-bundles.

In order to extend Theorem 4.2 to the twisted case, we focus on the local chart $\mathbb{C}/\mathbb{Z}_m$. Consider $\mathcal{L}$ a line $V$-bundle over $M$ and $L$ the corresponding parabolic line bundle over $X$. The local trivialization of $L$ is $\mathbb{Z}_m$-equivariant with respect to the following action

\[ t(z; z_1) = (tz; tkz_1), \quad 0 \leq k < \alpha. \]

Let $s$ be a holomorphic section of $L$. Note that $s$ is $\mathbb{Z}_m$-equivariant. In other words, it means that $(t \cdot s)(tz) = s(z)$.

With respect to the above trivialization, the section $s$ can be written as

\[ s(z) = z^k \hat{s}(z^m), \]

where $\hat{s}$ is a holomorphic function of $L$.

Let $(E, \Phi)$ be an $\mathcal{L}$-twisted Higgs $V$-bundle over $M$. The $\mathcal{L}$-twisted $V$-Higgs field $\Phi = (\phi_{ij})$ can be locally written as

\[ \phi_{ij} = \begin{cases} z^{k_i - k_j} \hat{\phi}_{ij}(z^m)(z^k \hat{s}(z^m)) & \text{if } k_i \geq k_j \\ 0 & \text{if } k_i < k_j, \end{cases} \]

where the local trivialization is the same as the one considered in §4. Let $F$ be the corresponding parabolic bundle over $(X, D)$ under the correspondence of Theorem 4.2. The corresponding section for an $\mathbb{L}$-twisted parabolic Higgs bundle is $z^k \hat{\phi}_{ij}(z) \hat{s}(z^m)$. By gluing the local charts, the $\mathcal{L}$-twisted $V$-Higgs field $\Phi$ gives us an $\mathbb{L}$-twisted parabolic Higgs field $\tilde{\Phi}$. This implies the correspondence in the twisted case. We therefore obtain the following:

**Proposition 5.6.** There is a bijective correspondence between isomorphism classes of holomorphic semistable (resp. stable) $\mathcal{L}$-twisted Higgs $V$-bundles with good trivialization $(E, \Theta, \Phi)$ and isomorphism classes of semistable (resp. stable) $\mathbb{L}$-twisted parabolic Higgs bundles $(F, \tilde{\Theta}, \tilde{\Phi})$.
Such an atlas defines the $V$-surface $M_\eta$ over $(X_\eta, \pi^{-1}(D))$, and the underlying space of $M_\eta$ is $X_\eta$. We have a natural covering of the $V$-surface $\pi : M_\eta \rightarrow M$, which is the spectral covering. Under the correspondence between Higgs $V$-bundles and parabolic Higgs bundles, we have the following corollary.

**Corollary 5.7.** Assume that the underlying surface of $M_\eta$ is nonsingular and the intersection of the set of branch points $B$ and the divisor $D$ is empty. Then there is a bijective correspondence between $\text{Higgs } V$-bundles and parabolic $\text{Higgs } V$-bundles, where $E$ is a $V$-bundle of rank $n$ over $M$ and $\Phi : E \rightarrow E \otimes \mathcal{L}$ a homomorphism with characteristic coefficients $\eta_i$. For $\rho : M_\eta \rightarrow M$, it is $\rho_*(\mathcal{L}) = \mathcal{L}$.

**Proof.** The proof follows from Proposition 5.6 (also Theorem 4.2) and Proposition 5.2. The correspondence is obtained from the following diagram:

\[
\begin{array}{ccc}
\text{line } V\text{-bundles over } M_\eta & \xrightarrow{\text{Proposition 5.6}} & \mathcal{L}\text{-twisted } V\text{-bundles over } M \\
\downarrow \text{Proposition 5.6} & & \downarrow \text{Proposition 5.2} \\
\text{parabolic line bundles over } X_\eta & \rightarrow & \text{parabolic } \mathcal{L}\text{-twisted Higgs bundles over } X.
\end{array}
\]

For our purposes, we are particularly interested in the following two cases of $\mathcal{L}\text{-twisted } V\text{-bundles}:

1. $\mathcal{L} = K(D)$ with trivial monodromy around each puncture $x \in D$;
2. $\mathcal{L} = K$ with monodromy $\frac{1}{2}$ around each puncture $x \in D$.

In the first case, $\frac{dz}{z}$ is a local section of $K(D)$, which is $\mathbb{Z}_2$-equivariant. It is easy to check that the corresponding local section for the chart of $X$ is $\frac{dw}{w}$, where $w = z^2$. Therefore we use the same notation $K(D)$ for the corresponding parabolic line bundle over $(X, D)$, of which the parabolic structure is trivial over each point $x \in D$. In this case, the correspondence studied in Proposition 5.6 and Theorem 4.2 is exactly between $K(D)$-twisted Higgs $V$-bundles and parabolic Higgs bundles.

In the second case, $dz$ is a local section of $K$. Under the same calculations as in §4, the section $dz$ is also $\mathbb{Z}_2$-equivariant. Let $w = z^2$; then

$$dz = \frac{dw}{w}.$$  

The variable can be considered as the local coordinate of the corresponding chart of $X$. More precisely, we consider the local section $\phi f(z)dz$, where $\phi$ is some holomorphic section of a $V$-bundle $\text{End}(E)$. We have

$$\phi f(z)dz = \phi z \frac{dw}{w}.$$  

This formula implies that the corresponding parabolic Higgs field not only preserves the filtration, but also maps the filtration $F_j$ strictly to $F_{j+1} \otimes K(D)$. Therefore the corresponding twisted parabolic Higgs bundle in this case is a strongly parabolic Higgs bundle. Details of this correspondence can be found in [5].

In conclusion, we have

**Theorem 5.8.**

1. Let $\mathcal{L} = K(D)$ with trivial monodromy around each puncture $x \in D$. There is a one-to-one correspondence between $\mathcal{L}\text{-twisted } V\text{-bundles and parabolic } V\text{-bundles}$.
2. Let $\mathcal{L} = K$ with monodromy $\frac{1}{2}$ around each puncture $x \in D$. There is a one-to-one correspondence between $\mathcal{L}\text{-twisted } V\text{-bundles and strongly parabolic } V\text{-bundles}$. 
5.3. Hitchin Fibration. Analogously to the classical BNR correspondence, Proposition 5.9 and Corollary 5.7 provide a way to describe the fiber of the parabolic Hitchin map \((K(D)\text{-twisted})\). Let \(\text{tot}(K(D))\) be the total space of the line bundle \(K(D)\). It can be written as

\[
\text{tot}(K(D)) = \text{Spec}(\text{Sym}^*(((K(D))^{-1}))
\]

We have the canonical projection \(\pi : \text{tot}(K(D)) \to X\). Let \(\lambda \in H^0(\pi^*K(D))\) be the tautological section. The characteristic polynomial of the Higgs field

\[
det(\lambda \cdot \text{id} - \pi^*\Phi) = \lambda^n + \eta_1\lambda^{n-1} + \ldots + \eta_n \in H^0(\text{tot}(K(D)), \pi^*(K(D)^n))
\]

defines the sections \(\eta_i \in H^0(X, (K(D))^i)\). The parabolic Hitchin map

\[
h : \mathcal{M}_{par}(X, D, \alpha, n) \to \bigoplus_{i=1}^n H^0(X, (K(D))^i)
\]
sends \((E, \Phi)\) to \((\eta_1, \ldots, \eta_n)\), where \((\eta_1, \ldots, \eta_n)\) is the coefficient of the characteristic polynomial of \(\Phi\). If \(\Phi\) is strongly parabolic, then the eigenvalues of \(\Phi\) will vanish at the divisor. Therefore, \(\eta_i \in H^0(X, K^iD^i \otimes \mathcal{O}_X(-D))\), and the Hitchin fibration is the map

\[
h : \mathcal{M}_{par}^*(X, D, \alpha, n) \to H = \bigoplus_{i=1}^n H^0(X, (K(D))^i) \otimes \mathcal{O}_X(-D))
\]
sending \(E\) to \(\eta_i\), where \(\mathcal{M}_{par}^*(X, D, \alpha, n)\) denotes the moduli space of strongly parabolic Higgs bundles with parabolic structure \(\alpha\). More generally, we have

\[
\mathcal{M}_{par}(X, D, n) \to \bigoplus_{i=1}^n H^0(X, K(D)^i).
\]

The parabolic Hitchin map \(\mathcal{M}_{par}(X, D) \to \bigoplus_i H^0(X, K(D)^i)\) is blind with respect to the parabolic structure, in other words, the parabolic Hitchin fibration of a regular point \(\eta \in \bigoplus_i H^0(X, K(D)^i)\) may contain two elements \((E, \alpha, \Phi)\) and \((E, \alpha', \Phi)\) for different parabolic structures \(\alpha \neq \alpha'\).

Considering weights as rational numbers with denominator \(m\), for a fixed positive integer \(m \geq 2\), we want to describe the fiber of the parabolic Hitchin map \(\mathcal{M}_{par}(X, D, n, m) \to \bigoplus_i H^0(X, K(D)^i)\). Note that we can construct the \(V\)-surface \(M\) over \((X, D)\) such that the action around each \(x \in D\) is the cyclic group \(Z_m\) of order \(m\). Then any point in \(\mathcal{M}_{par}(X, D, n, m)\) corresponds to a \(V\)-bundle over \(M\). This correspondence is bijective by Theorem 5.9, thus providing the following:

**Proposition 5.9.** The moduli space \(\mathcal{M}_{par}(X, D, n, m)\) is isomorphic to the moduli space of rank \(n\) \(V\)-bundles over \(M\), where \(M\) is the \(V\)-surface uniquely determined by the data \((X, D, m)\).

The Beauville-Narasimhan-Ramanan correspondence for \(V\)-surfaces provides now the following description of the fibers:

**Proposition 5.10.** The fiber of the parabolic Hitchin map

\[
\mathcal{M}_{par}(X, D, n, m) \to \bigoplus_{i=1}^n H^0(X, K(D)^i)
\]

over a regular point \(\eta \in \bigoplus_i H^0(X, K(D)^i)\) is isomorphic to the \(V\)-Picard group of the spectral covering \(M_\eta\) of \(M\), where \(M\) is uniquely determined by the data \((X, D, m)\).

Now let us consider a special case: \(n = 2\). For the moduli space of \(\text{SL}(2, \mathbb{R})\)-Higgs bundles (resp. \(\text{GL}(2, \mathbb{R})\)-Higgs bundles), N. Hitchin [14] proved that the fiber of the Hitchin fibration of a regular
point $\eta \in H^0(X, K^2)$ with a given determinant is biholomorphic to the Prym variety of the spectral covering $X_\eta \to X$. The Prym variety $\text{Prym}(X_\eta, X)$ is defined as

$$\text{Prym}(X_\eta, X) = \{ L \in \text{Jac}(X_\eta) | \tau^* L = L^{-1} \},$$

where $\tau : X_\eta \to X$ is the involution of the double covering $X_\eta \to X$.

On the moduli space of parabolic $\text{SL}(2, \mathbb{R})$-Higgs bundles $\mathcal{M}_{\text{par}}(\text{SL}(2, \mathbb{R}), X, D, n)$ (resp. $\text{GL}(2, \mathbb{R})$-Higgs bundles $\mathcal{M}_{\text{par}}(\text{GL}(2, \mathbb{R}), X, D, n)$), the parabolic Hitchin fibration of a regular point $\eta$ in the Hitchin base $H^0(X, K(D)^2)$ is exactly the Prym variety

$$\text{Prym}(M_\eta, M) = \{ L \in \text{Pic}_V(M_\eta) | \tau^* L = L^{-1} \},$$

of the spectral covering $M_\eta \to M$, where $M$ and $M_\eta$ are the corresponding $V$-surfaces of $X$ and $X_\eta$, and $\tau : M_\eta \to M_\eta$ is the involution of $M_\eta$.

Recall that we have the following short exact sequences for the $V$-Picard groups $\text{Pic}_V(M)$ and $\text{Pic}_V(M_\eta)$

$$0 \to \text{Pic}(X) \to \text{Pic}_V(M) \to \bigoplus_{i=1}^s \mathbb{Z}_2 \to 0,$$

$$0 \to \text{Pic}(X_\eta) \to \text{Pic}_V(M_\eta) \to \bigoplus_{i=1}^{2s} \mathbb{Z}_2 \to 0.$$

These exact sequences together with the $\Gamma$-equivariant condition give us the following short exact sequence for $\text{Prym}_V(M_\eta, M)$:

$$0 \to \text{Prym}(X_\eta, X) \to \text{Prym}_V(M_\eta, M) \to \bigoplus_{i=1}^s \mathbb{Z}_2 \to 0.$$

Summarizing the results of this section, we imply the following:

**Proposition 5.11.** The fiber of the parabolic Hitchin map

$$\mathcal{M}_{\text{par}}(X, D, 2, 2) \to H^0(X, K(D)^2)$$

is a finite number of copies of the Prym variety $\text{Prym}(M_\eta, M)$. This number of copies only depends on the parabolic structure $\alpha$.

5.4. **BNR Correspondence for $\mathcal{L}$-Twisted Higgs Bundles over a Root Stack.** In this subsection, we discuss the BNR correspondence for $\mathcal{L}$-twisted Higgs bundles over a root stack. Although we do not use this version of the correspondence in this paper, we include it here for completeness. In fact, the $V$-manifold has a natural structure as a root stack, thus the correspondence for $V$-bundles implies the correspondence for bundles over a root stack.

We first review the definition of a Higgs bundle over an algebraic stack $\mathfrak{X}$. A coherent sheaf $\mathcal{F}$ on $\mathfrak{X}$ is defined as follows. Let $U, V$ be two schemes, and let

$$f_U : U \to \mathfrak{X}, \quad f_V : V \to \mathfrak{X}$$

be two etale morphisms. Let $h : U \to V$ be a morphism of schemes such that the following diagram commutes

$$\begin{array}{ccc}
U & \xrightarrow{h} & V \\
\downarrow{f_U} & & \downarrow{f_V} \\
\mathfrak{X} & \xleftarrow{f_V} & \mathfrak{X}
\end{array}$$

A coherent sheaf $\mathcal{F}$ on $\mathfrak{X}$ consists of a collection of coherent sheaves $\mathcal{F}_U$ for each etale morphism $f_U : U \to \mathfrak{X}$ along with isomorphisms $a_h : \mathcal{F}_U \to h^\ast \mathcal{F}_V$. The coherent sheaf $\mathcal{F}$ is locally free if $\mathcal{F}_U$ is locally free for any etale morphism $U \to \mathfrak{X}$. If $\mathcal{F}$ is a locally free sheaf, we say $\mathcal{F}$ is a bundle over $\mathfrak{X}$. Let $X$ be the coarse moduli space of $\mathfrak{X}$. If $X$ is a Riemann surface, denote by $\omega_X$ the canonical bundle over the stack $\mathfrak{X}$, which is locally defined as $\omega_{X_U} := \omega_{U/X}$. 
Let $\mathcal{F}$ be a locally free sheaf on $\mathcal{X}$. A Higgs field $\Phi$ on $\mathcal{F}$ is a homomorphism $\Phi : \mathcal{F} \to \mathcal{F} \otimes \omega_{\mathcal{X}}$. Locally, $\Phi_U : \mathcal{F}_U \to \mathcal{F}_U \otimes \omega_U$ and the following diagram is commutative:

\[
\begin{array}{ccc}
\mathcal{F}_U & \xrightarrow{\Phi_U} & \mathcal{F}_U \otimes \omega_U \\
\downarrow^{a_h} & & \downarrow^{a_h \otimes a_{\mathcal{X}}^\omega} \\
\mathcal{h}^*\mathcal{F}_V & \xrightarrow{\Phi_V} & \mathcal{h}^*\mathcal{F}_V \otimes \mathcal{h}^*\omega_V.
\end{array}
\]

Now we consider the root stack. Let $\mathcal{X}$ be an algebraic stack and let $L$ be an invertible sheaf over $\mathcal{X}$. We fix a positive integer $r$ and take a section $s \in \Gamma(\mathcal{X}, L)$. The pair $(L, s)$ provides a morphism $\mathcal{X} \to [\mathbb{A}^1/\mathbb{G}_m]$. Denote by $\theta_r : [\mathbb{A}^1/\mathbb{G}_m] \to [\mathbb{A}^1/\mathbb{G}_m]$ the morphism induced by the $r$-th power maps on both $\mathbb{A}^1$ and $\mathbb{G}_m$. Clearly, the map $\theta_r$ sends a pair $(L, s)$ to its $r$-th tensor product $(L^r, s^r)$. The root stack $\mathcal{X}_{(L, s, r)}$ is defined as follows

\[ \mathcal{X}_{(L, s, r)} := \mathcal{X} \times [\mathbb{A}^1/\mathbb{G}_m], \theta_r [\mathbb{A}^1/\mathbb{G}_m]. \]

As a special case, let $\mathcal{X} = X$ be a scheme. Then the objects of $X_{(L, s, r)}$ over a scheme $S$ are quadruples $(f, M, t, \varpi)$, where $f : S \to X$ is a morphism, $M$ is an invertible sheaf on $S$, $t$ is a section in $\Gamma(S, M)$, and $\varpi : M^r \to f^*L$ is an isomorphism such that $\varpi(t^r) = f^*s$. If $X = \mathbb{A}^1$ with coordinate $x$, then we have

\[ X_{O_X, x, r} \cong [\mathbb{A}^1/\mu_r]. \]

I. Biswas, S. Majumder and M. L. Wong proved an equivalence of categories of Higgs bundles on $\mathcal{X}$ and strongly parabolic Higgs bundles on $X$, where $\mathcal{X} = X_{O_X(D), s, r}$ (Theorem 4.7 in [5]). Their approach can be easily extended to the $L$-twisted case. Let $L$ be a line bundle over $\mathcal{X}$, and let $\mathcal{L}$ be the parabolic line bundle over $(X, D)$ corresponding to $L$. With respect to the above notation, we have the following proposition.

**Proposition 5.12.** There is a one-to-one correspondence between $L$-twisted Higgs bundles over $\mathcal{X}$ and $L$-twisted parabolic Higgs bundles over $(X, D)$.

The idea in the proof of this proposition is similar to the one for Theorem 5.12 and Proposition 5.6. Let $\eta = (\eta_1, \ldots, \eta_n) \in \sum_{i=1}^n H^0(\mathcal{X}, \mathcal{L}^i)$ be an element in the Hitchin base for the stack $\mathcal{X}$. We can define the spectral covering $\mathcal{X}_\eta$ as the zero locus of

\[ \lambda^n + \eta_1 \lambda^{n-1} + \cdots + \eta_n. \]

Since $\mathcal{X}$ is a root stack, it is easy to check that $\mathcal{X}_\eta$ is also a root stack. The version of the correspondence for a root stack is then given in the following:

**Corollary 5.13 (BNR Correspondence for Stack).** There is a one-to-one correspondence between line bundles over $\mathcal{X}_\eta$ and $L$-twisted Higgs bundles over $\mathcal{X}$.

**Proof.** Similar to the proof of Corollary 5.7, this Corollary is directly implied by Proposition 5.10 and Proposition 5.12. \qed

### 5.5. Conclusion

With respect to the discussion in §4 and §5, we have one-to-one correspondences among the following six categories:

\[
\begin{array}{ccc}
L$-twisted Higgs V-bundles over $M & \xrightarrow{\text{Corollary 5.7}} & \text{line V-bundles over } M_n \\
\downarrow \text{Proposition 5.9} & & \downarrow \text{Proposition 5.10} \\
\text{parabolic } L$-twisted Higgs bundles & \xrightarrow{\text{Proposition 5.11}} & \text{parabolic line bundles over } X_n \\
\downarrow \text{Proposition 5.12} & & \downarrow \text{Proposition 5.12} \\
L$-twisted Higgs bundles over stack $\mathcal{X} & \xrightarrow{\text{Corollary 5.13}} & \text{line bundles over } \mathcal{X}_\eta.
\end{array}
\]

In §7 later on, we will use the BNR correspondence and the $V$-Prym variety to prove the connectedness of the components of the moduli space $\mathcal{M}_{\text{par}}(\text{Sp}(2n, \mathbb{R}))$ under several considerations for the parabolic structure.
6. Topological Invariants of the Moduli Space of Parabolic Sp($2n,\mathbb{R}$)-Higgs Bundles

**Definition 6.1.** Let $(V, \beta, \gamma)$ be a parabolic Sp$(2n, \mathbb{R})$-Higgs bundle over $(X, D)$. The parabolic Toledo invariant of $(V, \beta, \gamma)$ is defined as the rational number $\tau = \text{par deg}(V)$.

In [16] it is shown that for a semistable parabolic Sp$(2n, \mathbb{R})$-Higgs bundle, the parabolic Toledo invariant satisfies the inequality

$$|\tau| \leq n \left( g - 1 + \frac{s}{2} \right),$$

where $s$ is the number of points in the divisor $D$. We call maximal the parabolic Sp$(2n, \mathbb{R})$-Higgs bundles for which $\tau = n \left( g - 1 + \frac{s}{2} \right)$ and denote the components containing those by

$$\mathcal{M}^\text{max}_{\text{par}}(\text{Sp}(2n, \mathbb{R})) := \mathcal{M}^n_{\text{par}}(g - 1 + \frac{1}{2})(\text{Sp}(2n, \mathbb{R})).$$

In this maximal case and for a fixed square root $L_0$ of $K(D)$ there is a one-to-one correspondence, called the parabolic Cayley correspondence, which maps every maximal triple $(V, \beta, \gamma)$ to a triple $(W, \phi, c)$ for $W := V \otimes L_0^{-1}$ and for $\phi, c$ defined by

$$\phi = (\beta \otimes 1_{L_0}) \circ (\gamma \otimes 1_{L_0^{-1}}) : W = V \otimes L_0^{-1} \to V \otimes L_0^{\frac{s}{2}} = W \otimes K(D)^2,$$

$$c = \gamma \otimes 1_{L_0^{-1}} : W = V \otimes L_0^{-1} \to V^\vee \otimes K(D) \otimes L_0^{-1} = W^\vee.$$

Note also that the map $\gamma$ is an isomorphism in the maximal case, implying that $c$ is also an isomorphism and $\phi : W \to W \otimes K(D)^2$ is a $K(D)^2$-twisted parabolic Higgs field for $W$. Moreover, the parabolic structure on the bundle $V$ provides the construction of the corresponding $V$-surface $M$, where $M$ is the $V$-manifold with $s$-many marked points $p_1, ..., p_s$, around which the isotropy group is $\mathbb{Z}_2$, and $X$ is the underlying surface of $M$. Let us use the same notation $(V, \Phi)$ or $(V, \beta, \gamma)$ for the corresponding $V$-Higgs bundle over $M$. On the other hand, since the parabolic degree is equal to the degree as a $V$-bundle, we use the notation par deg($L$) to also mean the degree of $L$ as a $V$-bundle, while deg($L$) is the degree of $L$ over the underlying surface $X = |M|$. As a $V$-bundle morphism, the isomorphism $c$ induces a quadratic form on $W$. Hence, the structure group of $W$ is $O(n, \mathbb{C})$.

### 6.1. Topological Invariants of $\mathcal{M}^\text{max}_{\text{par}}(\text{Sp}(2n, \mathbb{R}))$

Topological invariants for maximal parabolic Sp$(2n,\mathbb{R})$-Higgs bundles are apprehended on the cohomology group $H^*_V(M, \mathbb{Z}_2)$. These cohomology groups were discussed in [16], §7, where we computed that

$$\text{rk}(H^1(M_V)) = 2g + s - 1,$$

$$\text{rk}(H^2(M_V)) = s.$$

For the Sp$(4,\mathbb{R})$-case we see the following:

1. If $\Lambda^2 W \neq 0$, the structure group of $W$ is $O(2, \mathbb{C})$ and every pair $(u, v)$ is a topological invariant for $W$, where $0 \neq u \in H^1_V(M, \mathbb{Z}_2)$ and $v \in H^2_V(M, \mathbb{Z}_2)$. Thus, there are clearly $2^{\text{rk}(H^2_V(M, \mathbb{Z}_2))(2^{2g+s-1} - 1)}$ many distinct pairs $(u, v)$. Denote by $\mathcal{M}^{u,v}_{\text{par}}$ the moduli space corresponding to $(u, v)$.

2. If $\Lambda^2 W = 0$, then the structure group can be reduced to $SO(2, \mathbb{C}) \subset O(2, \mathbb{C})$. From the identification $SO(2, \mathbb{C}) \cong \mathbb{C}^*$, $W$ can be decomposed as a direct sum $W = L \oplus L^\vee$, where $L$ is a line $V$-bundle and $L^\vee$ is the dual of $L$. Now, stability for the map $\phi : W \to W \otimes K(D)^2$, provides the existence of a non-trivial holomorphic map $L \to L^\vee \otimes K(D)^2$, therefore it holds necessarily that $\text{par deg}(L) \leq 2g - 2 + s$.

   a. If $\text{par deg}(L) \neq 2g - 2 + s$, then every possible value of the degree gives at least one topological invariant, thus providing at least $2g - 2 + s$ different non-negative values.

   Now we want to describe all possible topological invariants for line $V$-bundles with degree smaller than $2g - 2 + s$. Recall from §4.2 that the $V$-Picard group $\text{Pic}_V(M)$ classifies all
line $V$-bundles over $M$. The $V$-Picard group has the following short exact sequence

$$0 \to \text{Pic}(X) \to \text{Pic}_V(M) \to \bigoplus_{x \in D} \mathbb{Z}_2 \to 0.$$ 

By definition, the parabolic degree is the sum of the classical degree and the weights

$$\text{par} \text{deg} = \text{deg} + \text{weights}.$$ 

In fact, we can understand this definition from the above exact sequence about $\text{Pic}_V(M)$. The classical deg comes from $\text{Pic}(X)$ and the weights come from $\bigoplus_{x \in D} \mathbb{Z}_2$. From the exact sequence, it is also clear that $\text{Pic}_V(X)$ is not necessarily connected. Then every pair $(d, w)$, where $d \in \text{Pic}(X)$ the classical degree and $w \in \bigoplus_{x \in D} \mathbb{Z}_2$ the weight, describes a topological invariant for the line $V$-bundles. Although different pairs $(d, w)$ may have the same parabolic degree, they provide different topological invariants for line $V$-bundles. Denote by $\mathcal{M}^{(d, w)}_{\text{par}}$ the moduli space in this case.

b. If $\text{par} \text{deg}(L) = 2g - 2 + s$, we have $L^2 \cong K(D)^2$. This describes parabolic $\text{Sp}(4, \mathbb{R})$-Higgs bundles $(E = V \oplus V^\vee, \Phi)$ with $V = N \oplus N^\vee K(D)$, for a line bundle $N = K(D)^{\frac{g}{2}}$. Thus, square roots of $K(D)$ parameterize components containing such Higgs bundles, and this contributes to $2^{2g+s-1}$ topological invariants. Denote by $\mathcal{M}^{0,2g-2+s,L}_{\text{par}}$ the moduli space in this case.

The investigation of the $\text{Sp}(2n, \mathbb{R})$ case, $n \geq 3$, is analogous to the one for $\text{Sp}(4, \mathbb{R})$. We define the Cayley partner $(W, c, \phi)$ similarly and describe the topological invariants for all possible Cayley partners. By Proposition 3.3, we can discuss this problem in two cases: $\beta = 0$ and $\beta \neq 0$.

1. If $\beta = 0$, it means that the corresponding morphism $\phi$ in the Cayley partner is also trivial. Therefore the Cayley partner reduces to $(W, c)$, where $c$ is an isomorphism of the parabolic $\text{GL}(n, \mathbb{R})$-bundle $W$, or equivalently the $V$-bundle $W$. Thus the $V$-cohomology groups $H^1_V(M, \mathbb{Z}_2)$, $H^2_V(M, \mathbb{Z}_2)$ are topological invariants for such bundle $W$. In this case, we have $2^s \cdot 2^{2g+s-1}$ many topological invariants. Denote by $\mathcal{M}^{u,v}_{\text{par}}(\text{Sp}(2n, \mathbb{R}))$ the component of $V$-Higgs bundle $(E, \Phi)$ such that the topological invariants of its Cayley partner $(W, \phi, c)$ are $u \in H^1_V(M, \mathbb{Z}_2)$ and $v \in H^2_V(M, \mathbb{Z}_2)$.

2. If $\beta \neq 0$, in either Case (2) or Case (3) of Proposition 3.3 one needs to fix a square root $L$ of the bundle $K(D)$. Note that we are taking the square root of a $V$-bundle. Denote by $\mathcal{M}^{0,2g-2+s,L}_{\text{par}}(\text{Sp}(2n, \mathbb{R}))$ the moduli space in this case and there are $2^{2g+s-1}$ many such choices for the square root $L$.

7. Connected Components of $\mathcal{M}^{\text{max}}_{\text{par}}(\text{Sp}(2n, \mathbb{R}))$

Based on the previous two sections, we will now prove that the moduli spaces $\mathcal{M}^{u,v}_{\text{par}}$, $\mathcal{M}^{0,(d,w)}_{\text{par}}$ and $\mathcal{M}^{0,2g-2+s,L}_{\text{par}}$ for each possible value of the corresponding topological invariants are connected. As explained in §3, it is enough to prove that the subspace of local minima $\mathcal{N}$ for each of those components is connected. The proofs below are for the case $G = \text{Sp}(4, \mathbb{R})$; for the case $G = \text{Sp}(2n, \mathbb{R})$ when $n \geq 3$ the proofs are no different, thus we state directly the analogous results.

**Proposition 7.1.** $\mathcal{M}^{u,v}_{\text{par}}$ is connected, where $u \neq 0$.

**Proof.** As seen in Proposition 3.3 $u = w_1(W) \neq 0$ only for triples $(V, \beta, \gamma)$ of the type (1), that is, for those which $\beta = 0$. This implies that the Higgs field $\phi$ in the Cayley partner vanishes, hence we consider the moduli space for the pairs $(W, c)$.

Notice that the first $V$-cohomology group is isomorphic to $\text{Hom}(\pi^1_V(M), \mathbb{Z}_2)$. Moreover,

$$\text{Hom}(\pi_V^1(M), \mathbb{Z}_2) \cong \text{Hom}(\pi_1(X/D), \mathbb{Z}_2).$$
Thus, given an element \( u \in H^1_1(M, \mathbb{Z}_2) \), we can construct a degree two etale covering over the underlying surface with punctures

\[
\pi_u : X_u / \pi_u^{-1}(D) \to X/D,
\]

where \( X_u \) is a compact surface. The existence of \( X_u \) is provided by Theorem 1.1 in [7]. Clearly,

\[
\pi_u^* W|_{X/D} = L|_{X/D} \bigoplus L^{-1}|_{X/D},
\]

where \( L \) is a line bundle over \( X_u \), with \( \pi^* W \) an isomorphism of \( \pi_u^* W \). A \( V \)-surface \( M_{\pi_u} \) with underlying surface \( \pi_u \) can be constructed with local charts given by

\[
\begin{align*}
\phi_y : U_y & \to D^k / \mathbb{Z}_2, \\
\phi_p : U_p & \to D^k,
\end{align*}
\]

\( y \in \pi_u^{-1}(D); \quad p \in M \backslash \pi_u^{-1}(D). \)

There is also a natural covering of \( V \)-surface \( \pi_u : M_{\pi_u} \to M \), thus there are three covering morphisms summarized below

- etale: \( X_u / \pi_u^{-1}(D) \to X/D \),
- ramified: \( X_u \to X \),
- \( V \)-surface: \( M_{\pi_u} \to M \).

We shall use the same notation \( \pi_u \) for all these coverings.

\[
\begin{array}{ccc}
X_u / \pi_u^{-1}(D) & \xrightarrow{\pi_u} & X_u \\
\downarrow & & \downarrow \\
X/D & \xleftarrow{\pi_u} & M
\end{array}
\]

The direct sum

\[
\pi_u^* W|_{X/D} = L|_{X/D} \oplus L^{-1}|_{X/D}
\]

can be extended to the \( V \)-surface \( M_{\pi_u} \). Let \( \tau : M_{\pi_u} \to M_{\pi_u} \) be the involution interchanging the coverings and clearly \( \tau^* L = L^{-1} \). From the discussion following Proposition [5,10] \( L \) is a well-defined element in the Prym variety \( \text{Prym}(M_{\pi_u}, M) \) of \( V \)-surfaces.

We now turn to these line \( V \)-bundles \( L \) in the Prym variety \( \text{Prym}(M_{\pi_u}, M) \). In our case, the monodromy group is \( \mathbb{Z}_2 \), hence there are only two possible monodromy actions around \( p \in \pi_u^{-1}(D) \), namely 0 and \( \frac{1}{2} \). If \( p_1, p_2 \in \pi_u^{-1}(D) \) and \( \pi_u(p_1) = \pi_u(p_2) \), then the monodromy action around these two points should be the same described by the condition \( \tau^* L = L^{-1} \). The short exact sequence

\[
0 \to \text{Pic}(X_u) \to \text{Pic}(M_{\pi_u}) \to \bigoplus_{i=1}^s \mathbb{Z}_2 \to 0
\]

implies the following sequence for the Prym variety

\[
0 \to \text{Prym}(X_u, X) \to \text{Prym}(M_{\pi_u}, M) \to \bigoplus_{i=1}^s \mathbb{Z}_2 \to 0.
\]

Since the covering \( X_u \to X \) is a ramified covering, \( \text{Prym}(X_u, X) \) is connected. Therefore, each element in \( \bigoplus_{i=1}^s \mathbb{Z}_2 \) provides a connected component of the Prym variety \( \text{Prym}(M_{\pi_u}, M) \).

The above argument implies that given a weight \( w \) and an element in the first \( V \)-cohomology group \( u \in \text{Hom}(\pi_1(X), \mathbb{Z}_2) \), the space of all such pairs \( (W, c) \) is connected. Now we only have to show that we can use the second \( V \)-cohomology \( H^2_1(M, \mathbb{Z}_2) \) to describe all possible weights in \( \bigoplus_{i=1}^s \mathbb{Z}_2 \).

For the \( V \)-manifold \( M \), the exact sequence

\[
0 \to \mathbb{Z} \to O_{M_v} \to O_{M_v}^* \to 0
\]
provides that
\[ H^1_V(M, O_{M_V}) \to H^1_V(M, O^*_{M_V}) \xrightarrow{=} H^2_V(M, \mathbb{Z}). \]
The first cohomology group \( H^1_V(M, O^*_{M_V}) \) is exactly the \( V \)-Picard group \( \text{Pic}_V(M) \). Therefore, there is a morphism
\[ \varpi : \text{Pic}_V(M) \to H^2_V(M, \mathbb{Z}). \]
By taking the \( \mathbb{Z}_2 \) coefficient, it is easy to see that the morphism \( \varpi \) induces the isomorphism
\[ \bigoplus_{i=1}^s \mathbb{Z}_2 \cong H^2_V(M, \mathbb{Z}). \]

**Corollary 7.2.** The number of all the connected components of the form \( \mathcal{M}^{u,v}_{\text{par}} \) is \( 2^s (2g+s-1) \).

**Proof.** Follows from the fact that \( \text{rk}(H^1(M_V)) = 2g + s - 1 \) and \( \text{rk}(H^2(M_V)) = s \).

**Proposition 7.3.** \( \mathcal{M}^{0,(d,w)}_{\text{par}} \) is connected.

**Proof.** Denote by \( \mathcal{N}^{0,(d,w)}_{\text{par}} \) the subspace of local minima of \( \mathcal{M}^{0,(d,w)}_{\text{par}} \). We show that \( \mathcal{N}^{0,(d,w)}_{\text{par}} \) is connected. From the discussion in §4.2 and §5.3, we know the \( V \)-Picard group \( \text{Pic}_V(M) \) is not necessarily connected. If we consider the subgroup \( \text{Pic}_w(M) \), which consists of all line \( V \)-bundles with a given fixed weight \( w \), this subgroup \( \text{Pic}_w(M) \) is isomorphic to the classical Picard group \( \text{Pic}(X) \) and so \( \text{Pic}_w(M) \) is connected. Denote by \( \text{Pic}^d_w(X) \) the subvariety of \( \text{Pic}_w(X) \) with fixed degree \( d \). It is clear that any line \( V \)-bundle in \( \text{Pic}^d_w(X) \) has the same parabolic degree; denote by \( l \) the corresponding parabolic degree. We shall prove the statement in two cases, namely when \( d = 0 \) and when \( d > 0 \).

When \( d = 0 \), we claim that the parabolic Higgs field \( \Phi \) is zero. In other words, the parabolic Higgs field of any point in \( \mathcal{N}^{0,(0,w)}_{\text{par}} \) is zero. By Proposition 5.3, the moduli space \( \mathcal{N}^{0,(0,w)}_{\text{par}} \) of local minima is isomorphic to the moduli space of pairs \((W,c)\), where \( W = L \oplus L' \), \( L \) is a degree 0 line bundle, and \( c = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \) with respect to the above decomposition. There is a surjective continuous map \( P \text{ic}^0_w(X) \to \mathcal{N}^{0,(0,w)}_{\text{par}} \) given by taking \( L \) to the pairs \((W,c)\). Hence, the moduli space \( \mathcal{N}^{0,(0,w)}_{\text{par}} \) of local minima is connected. Now we claim that the parabolic Higgs field \( \Phi \) is zero. If \( \Phi \) is not zero, then \( L' \) is a \( \Phi \)-invariant sub-line bundle of \( W \). This means that \( W \) is semistable, but not stable, and thus finishes the proof for the first case \( d = 0 \).

In the second case \( d > 0 \), the parabolic Higgs field \( \Phi \) cannot be zero, otherwise the subbundle \( L \) will violate the stability condition. Therefore, critical points should be as described in case (2) of Proposition 5.3. The parabolic Higgs field \( \Phi \) of a critical point can be written in the following form \( \Phi = \begin{pmatrix} 0 & 0 \\ \gamma & 0 \end{pmatrix} \), where \( \gamma \in H^0(X, (L'K(D))^2) \). Thus, the subvariety \( \mathcal{N}^{0,(d,w)}_{\text{par}} \) fits into the following pull-pack diagram
\[
\begin{array}{ccc}
\text{Pic}^d_w(X) & \xrightarrow{\cong} & \mathcal{N}^{0,(d,w)}_{\text{par}} \\
\downarrow \pi & & \downarrow L \rightarrow (L'K(D))^2 \\
S^{4g-4+2s-2l}(X) & \xrightarrow{\text{D}} & \text{Pic}^{4g-4+2s-2l}(X)
\end{array}
\]
where \( \pi(W,C,\Phi) = (\Phi) \). This shows that \( \mathcal{N}^{0,(d,w)}_{\text{par}} \) is connected also when \( d > 0 \).

**Corollary 7.4.** The number of all the connected components of the form \( \mathcal{M}^{0,(d,w)}_{\text{par}} \) is \( (2g-2+s)2^s \).
Proof. We calculate the number of all possible pairs \((d, w)\), where \(d \in \text{Pic}(X)\) is the classical degree of the parabolic line bundle and \(w\) is an element in \(\bigoplus_{i=1}^{s} \mathbb{Z}/2\); it is a combinatorial problem to determine the number of all pairs \((d, w)\). Let \(k(w)\) be the corresponding weight of \(w\) which is a rational number with denominator 2. In general,

\[ k(w) = \frac{\text{the number of 1 in } w}{2}. \]

Given an integer \(0 \leq k \leq s\), there are \(\binom{s}{k}\) many choices for the weight \(w\) such that \(2k(w) = k\).

Now we fix a weight \(w \in \bigoplus_{i=1}^{s} \mathbb{Z}/2\). We calculate the number of all possible degrees \(d\) depending on the parity of \(2k(w)\). By the definition of parabolic degree, we have

\[ 0 \leq d + k(w) < 2g - 2 + s. \]

Therefore, the range for \(d\) is

\[ -k(w) \leq d < 2g - 2 + s - k(w). \]

Fixing \(k(w)\), the number of all possible values for \(d\) is \(2g - 2 + s\). Based on the above discussion, the number of all possible pairs \((d, w)\) is

\[ \sum_{2k(w)=0}^{s} \binom{s}{2k(w)} (2g - 2 + s)^{2}. \]

\( \square \)

Proposition 7.5. \(\mathcal{M}_{\text{par}}^{0, 2g-2+s, L}\) is connected.

Proof. In this case, the bundle \(W\) is completely determined by \(L\). Thus the moduli space \(\mathcal{M}_{\text{par}}^{0, 2g-2+s, L}\) is isomorphic to the moduli space of parabolic Higgs fields \(\Phi \in H^0(\text{End}(W) \otimes K(D))\), where \(\Phi\) is symmetric with respect to the matrix \(\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}\). Therefore, the Higgs field \(\Phi\) (more precisely the map \(\gamma\)) is of the following form

\[ \Phi = \begin{pmatrix} \phi_{11} & \phi_{12} \\ \phi_{12} & \phi_{22} \end{pmatrix}. \]

Hence, the moduli space \(\mathcal{M}_{\text{par}}^{0, 2g-2+s, L}\) is isomorphic to the connected space

\[ H^0(X, (K(D))^2) \bigoplus H^0(X, (K(D))^4) \bigoplus H^0(X, (K(D))^2). \]

\( \square \)

Corollary 7.6. The number of all the connected components of the form \(\mathcal{M}_{\text{par}}^{0, 2g-2+s, L}\) is \(2^{2g+s-1}\).

Combining the results of this section, we deduce an exact component count for the moduli space of maximal parabolic \(\text{Sp}(4, \mathbb{R})\)-Higgs bundles:

Theorem 7.7. The moduli space \(\mathcal{M}_{\text{par}}^{\text{max}}(\text{Sp}(4, \mathbb{R}))\) of parabolic maximal \(\text{Sp}(4, \mathbb{R})\)-Higgs bundles with all weights rational having denominator 2 over a compact Riemann surface \(X\) of genus \(g\) with a divisor of \(s\)-many distinct points on \(X\), such that \(2g - 2 + s > 0\), has \((2s + 1)^{2}2^{2g+s-1} + (2g - 3 + s)^{2}2^{s}\) many connected components.

The proof that the analogous subspaces of \(\mathcal{M}_{\text{par}}^{\text{max}}(\text{Sp}(2n, \mathbb{R}))\) for \(n \geq 3\) are connected is similar, thus providing the following:
Theorem 7.8. For \( n \geq 3 \), the moduli space \( \mathcal{M}_{\text{par}}^{\max}(\text{Sp}(2n, \mathbb{R})) \) of parabolic maximal \( \text{Sp}(2n, \mathbb{R}) \)-Higgs bundles with all weights rational having denominator 2 over a compact Riemann surface \( X \) of genus \( g \) with a divisor of \( s \)-many distinct points on \( X \), such that \( 2g - 2 + s > 0 \), has \( (2^s + 1)2^{2g+s-1} \) many connected components.

8. CONNECTED COMPONENTS OF \( \mathcal{M}_{\text{par}}^{\max}(\text{Sp}(2n, \mathbb{R})) \) WITH FIXED WEIGHT \( \frac{1}{2} \)

In this section we further restrict to the moduli space \( \mathcal{M}_{\text{par}}^{\max}(\text{Sp}(2n, \mathbb{R}), \hat{\alpha}) \) of maximal parabolic \( \text{Sp}(2n, \mathbb{R}) \)-Higgs bundles \( (V, \beta, \gamma) \) for a fixed parabolic structure \( \hat{\alpha} \) on the parabolic bundle \( V \) described by a trivial flag over each point \( x \in D \) and weight \( \frac{1}{2} \).

The maximality of \( (V, \beta, \gamma) \) defines a Cayley partner \( (W, c, \phi) \) with \( W \) having also a fixed parabolic structure induced by the one on \( V \). We now notice that among the three apparent cases (1), (2a) and (2b) from §6.1 there is a difference appearing only in Case (2a). In this case \( W = L \oplus L' \), however the parabolic degree of \( L \) is now also fixed satisfying

\[
0 \leq \text{par deg}(L) < 2g - 2 + s.
\]

The parabolic degree \( \text{par deg}(L) \) defines a topological invariant and with a similar proof as in Proposition 7.3 we can prove that the subspaces \( \mathcal{M}_{\text{par}}^{\max}(\text{Sp}(2n, \mathbb{R}), \hat{\alpha}) \) are all connected. We imply the following corollary, which verifies the prediction for the exact number of connected components from [10]:

Corollary 8.1. The number of connected components of the moduli space \( \mathcal{M}_{\text{par}}^{\max}(\text{Sp}(4, \mathbb{R}), \hat{\alpha}) \) with fixed trivial filtration and weight \( \frac{1}{2} \) is

\[
2^{2g+s-1}(2^s + 1) + (2g - 2 + s) - 2^s.
\]

Remark 8.2. The number of connected components is the same for any parabolic structure \( \alpha \) in which all the weights are rational numbers with denominator 2, in other words, the above component count does not depend on the fixed filtration of the parabolic bundle.

9. THE CASE OF RATIONAL Weights

We can analogously consider maximal \( \text{Sp}(2n, \mathbb{R}) \)-Higgs bundles for a more general choice of weights.

Definition 9.1. The parabolic \( \text{Sp}(2n, \mathbb{R}) \)-Higgs bundle \( (V, \beta, \gamma) \) with weight type of \( (m_i)_{1 \leq i \leq s} \) is defined to be the parabolic Higgs bundle with \( (\beta, \gamma) \) as in Definition 2.7, and the weight \( \alpha_{i,j} \) at each point \( x_i \in D \) in the parabolic structure of \( V \) is an integral multiple of \( \frac{2}{m_i} \), for \( 1 \leq i \leq s, 1 \leq j \leq n \).

Since the proof for maximality of the Toledo invariant does not depend on the parabolic structure, we still have \( |\text{par deg } V| \leq n \left( g - 1 + \frac{2}{m} \right) \). So when \( \text{par deg } V = n \left( g - 1 + \frac{2}{m} \right) \), we may still call \( V \) the maximal parabolic \( \text{Sp}(2n, \mathbb{R}) \)-Higgs bundle with weight type of \( (m_i)_{1 \leq i \leq s} \). The moduli space of polystable maximal parabolic \( \text{Sp}(2n, \mathbb{R}) \)-Higgs bundles with weight type of \( (m_i)_{1 \leq i \leq s} \) is denoted by

\[
\mathcal{M}_{\text{par},(m_1,...,m_s)}^{\max}(\text{Sp}(2n, \mathbb{R})).
\]

We can calculate the \( V \)-cohomology similarly on a local chart \([D/\mathbb{Z}_m]\), where \( D \) is the unit disk and let \( \mathbb{Z}_m \) act on \( D \) by multiplying the \( m \)-th root of unity \( e^{\frac{2\pi i}{m}} \). Then we can calculate the \( \mathbb{Z}_2 \) cohomology of \( D \times_{\mathbb{Z}_m} \mathbb{E}\mathbb{Z}_m \) following facts from the group cohomology of \( \mathbb{Z}_m \). Note that:

\[
H^2(D \times_{\mathbb{Z}_m} \mathbb{E}\mathbb{Z}_m, \mathbb{Z}_2) = \mathbb{Z}_2/m\mathbb{Z}_2 = \begin{cases} \mathbb{Z}_2 & \text{if } m \text{ is even} \\ 0 & \text{if } m \text{ is odd} \end{cases}
\]

\[
H^1(D \times_{\mathbb{Z}_m} \mathbb{E}\mathbb{Z}_m, \mathbb{Z}_2) = m - \text{torsion submodule of } \mathbb{Z}_2 = \begin{cases} \mathbb{Z}_2 & \text{if } m \text{ is even} \\ 0 & \text{if } m \text{ is odd} \end{cases}
\]

Remark 9.2. The coefficient \( \mathbb{Z}_2 \) in the cohomology is coming from the \( O(n, \mathbb{C}) \) structure in the Cayley partner, and it is not coming from the choice of weights at each point.
Denote by $s_0$ the number of the even $m_i$ in the collection $(m_i)_{1 \leq i \leq s}$ and by $s_1$ the number of the odd $m_i$, so clearly $s = s_0 + s_1$. From a similar Mayer-Vietoris sequence as the one considered in §7 of [16], it follows that the corresponding $V$-cohomology for the corresponding $V$-surface $M_V$ has rank

$$\text{rk}(H^1(M_V, \mathbb{Z}_2)) = 2g + s_0 - 1; \quad \text{rk}(H^2(M_V, \mathbb{Z}_2)) = s_0.$$ 

Topological invariants for elements in $\mathcal{M}^\text{max}_{\text{par}, (m_1, \ldots, m_s)}(\text{Sp}(2n, \mathbb{R}))$ can be similarly obtained, simply replacing $s$ by $s_0$ in §6.

For the case of $\mathcal{M}^\text{max}_{\text{par}, (m_1, \ldots, m_s)}(\text{Sp}(4, \mathbb{R}))$:

1. If $\wedge^2 W \neq 0$, the structure group is $O(2, \mathbb{C})$ and we still have $0 \neq u \in H^1_V(M, \mathbb{Z}_2)$ and $v \in H^2_V(M, \mathbb{Z}_2)$, thus giving $2^{s_0}(2^{2g+s_0-1}-1)$ many different pairs $(u, v)$. Denote by $\mathcal{M}^{(u,v)}_{\text{par}, (m_1, \ldots, m_s)}$ the moduli space of pairs with fixed $(u, v)$.

2. If $\wedge^2 W = 0$, then we still have $W = L \oplus L^\vee$ and $\text{par deg}(L) \leq 2g - 2 + s$.

   a. If $\text{par deg}(L) \neq 2g - 2 + s$, we need to describe all possible positive degrees less than $2g - 2 + s$. Note that now the exact sequence of the Picard $V$-group is

   $$0 \to \text{Pic}(X) \to \text{Pic}_V(M) \to \bigoplus_{i=1}^s \mathbb{Z}_{m_i} \to 0,$$

   while for each choice of an element $(w_i) \in \bigoplus_{i=1}^s \mathbb{Z}_{m_i}$, we have an integral degree $d$ such that $d + \sum \frac{k_i}{m_i} < 2g - 2 + s$. These form the moduli space $\mathcal{M}^{(d,w)}_{\text{par}, (m_1, \ldots, m_s)}$.

   b. If $\text{par deg}(L) = 2g - 2 + s$, then $L^2 = K(D)^2$, and the number of square roots of $K(D)$ is similarly the rank of 2-torsion in $H^1(M_V, \mathbb{Z})$, which is $2^{2g+s_0-1}$ as expected. Denote the pairs in this case by $\mathcal{M}^{0,2g-2+s_0,L}_{\text{par}, (m_1, \ldots, m_s)}$.

For the case of $\mathcal{M}^\text{max}_{\text{par}, (m_1, \ldots, m_s)}(\text{Sp}(2n, \mathbb{R}))$, we similarly get:

1. If $\beta = 0$, then our moduli spaces are parametrized by $u \in H^1_V(M, \mathbb{Z}_2)$ and $v \in H^2_V(M, \mathbb{Z}_2)$.

2. If $\beta \neq 0$ then there are $2^{2g+s_0-1}$ choices of square roots of $K(D)$.

The only case for which the weight with odd monodromy does contribute is that of $\text{Sp}(4, \mathbb{R})$, when $W = L \oplus L^\vee$, with $\text{deg} L \neq 2g - 2 + s$. In this situation, we can first choose the number $(k_1, \ldots, k_s)$, and $d$ must satisfy the inequality

$$-\sum_{i=1}^s \frac{k_i}{m_i} \leq d < 2g - 1 + s - \sum_{i=1}^s \frac{k_i}{m_i}.$$

Therefore, there are $2g - 1 + s$ choices for $d$, for any choice of $(k_1, \ldots, k_s)$. The total number of such components is thus

$$(2g - 1 + s) \prod_{i=1}^s m_i = (2g - 1 + s_0 + s_1) \prod_{i=1}^s m_i.$$ 

From Propositions 7.1, 7.3, 7.5, the components $\mathcal{M}^{(u,v)}_{\text{par}, (m_1, \ldots, m_s)}, \mathcal{M}^{(d,w)}_{\text{par}, (m_1, \ldots, m_s)}, \mathcal{M}^{0,2g-2+s_0,L}_{\text{par}, (m_1, \ldots, m_s)}$ are all connected.

In conclusion, we have the following theorems

**Theorem 9.3.** Let $X$ be a compact Riemann surface of genus $g$ with a divisor $D$ of $s$-many distinct points on $X$, such that $2g - 2 + s > 0$. Then, the moduli space of polystable maximal parabolic $\text{Sp}(4, \mathbb{R})$-Higgs bundles on $(X, D)$ with weight type $(m_i)_{1 \leq i \leq s}$ has

$$(2^{s_0} + 1)2^{2g+s_0-1} - 2^{s_0} + (2g - 2 + s) \prod_{i=1}^s m_i$$

connected components, where $s_0$ is the number of the even $m_i$ in the collection $(m_i)_{1 \leq i \leq s}$.

The case when $n \geq 3$ is simpler:
Theorem 9.4. Let $X$ be a compact Riemann surface of genus $g$ with a divisor $D$ of $s$-many distinct points on $X$, such that $2g - 2 + s > 0$. Then, for $n \geq 3$ the moduli space of polystable maximal parabolic $Sp(2n,\mathbb{R})$-Higgs bundles on $(X, D)$ with weight type $(m_i)_{1 \leq i \leq s}$ has

$$(2^{s_0} + 1)2^{2g+s_0-1}$$

connected components, where $s_0$ is the number of the even $m_i$ in the collection $(m_i)_{1 \leq i \leq s}$.

Before we move on to the next Corollary, we introduce the reducible and irreducible parabolic structure $\alpha$ with respect to the given weight type $(m_i)_{1 \leq i \leq s}$. By definition, the parabolic structure is uniquely determined by the weights over each puncture $x \in D$, thus let $\alpha = (\alpha_{ij})_{1 \leq i \leq s, 1 \leq j \leq n}$, where $(\alpha_{ij})_{1 \leq j \leq n}$ is the set of weights over the puncture $x_i$ with the same denominator $m_i$. Let $\alpha_{ij} = \frac{k_{ij}}{m_i}$, where $k_{ij}$ is a positive integer. For any $1 \leq i \leq s$, if there is at least one numerator $k_{ij}$ such that $k_{ij}$ and $m_i$ are coprime, the parabolic structure $\alpha$ is called irreducible. Otherwise, the parabolic structure $\alpha$ is called reducible.

By using the same arguments as in §8, we also obtain

Corollary 9.5. Let $X$ be a compact Riemann surface of genus $g$ with a divisor $D$ of $s$-many distinct points on $X$, such that $2g - 2 + s > 0$. Then, the moduli space of polystable maximal parabolic $Sp(4,\mathbb{R})$-Higgs bundles on $(X, D)$ with any irreducible parabolic structure $\alpha$ has

$$(2^{s_0} + 1)2^{2g+s_0-1} - 2^{s_0} + (2g - 2 + s)$$

connected components, where $s_0$ is the number of the even $m_i$ in the collection $(m_i)_{1 \leq i \leq s}$.

To deal with the reducible case, we can turn a reducible parabolic structure into an irreducible one by fraction reduction. Then, this goes back to the irreducible case as in Corollary 9.5.
