Supporting Information

ABSTRACT: Phosphodiesterase 9 (PDE9) inhibitors have been studied as potential therapeutics for treatment of diabetes and Alzheimer’s disease. Here we report a potent PDE9 inhibitor 3r that has an IC50 of 0.6 nM and >150-fold selectivity over other PDEs. The HepG2 cell-based assay shows that 3r inhibits the mRNA expression of phosphoenolpyruvate carboxykinase and glucose 6-phosphatase. These activities of 3r, together with the reasonable pharmacokinetic properties and no acute toxicity at 1200 mg/kg dosage, suggest its potential as a hypoglycemic agent. The crystal structure of PDE9-3r reveals significantly different conformation and hydrogen bonding pattern of 3r from those of previously published 28s. Both 3r and 28s form a hydrogen bond with Tyr424, a unique PDE9 residue (except for PDE8), but 3r shows an additional hydrogen bond with Ala452. This structure information might be useful for design of PDE9 inhibitors.

INTRODUCTION

Diabetes mellitus (DM) is a group of metabolic diseases that feature high blood sugar levels in patients. There are three main types of DM: type I or insulin-dependent DM in which the body fails to produce insulin; type II or insulin resistant DM in which there is dysregulation of insulin production/secretion as well as decreased sensitivity of peripheral tissues to insulin; and gestational diabetes that is typically associated with pregnant women.1 DM affects 26 million Americans or 8.3% population in the United States (www.cdc.gov/diabetes/surveillance) and has become a worldwide threat to public health. Thus, discovery of hypoglycemic agents with strong potency and weak side effect is highly desirable.

Targeting at the signaling pathway of cyclic guanosine monophosphate (cGMP), which is a second messenger and plays critical roles in many physiological processes, appears to be a new promising direction to fight DM. An early study showed that the platelet cGMP concentration and the NO production were increased by insulin in dose-dependent manner.2 Later, the NO/cGMP signaling pathway was shown to attenuate vascular inflammation and insulin resistance,3,4 and delay oocyte aging in DM.5 Thus, regulation of cellular cGMP, which can be achieved via inhibition of phosphodiesterases (PDEs), would potentially be a strategy for treatment of DM. PDEs are a superfamily of enzymes that hydrolyze cGMP and cAMP and have been studied as drug targets for treatment of human diseases.6–9 Twenty-one human PDE genes are classified into 11 families and encode >100 isoforms of proteins. PDE5, PDE6, and PDE9 specifically recognize cGMP as their substrate, while PDE4, PDE7, and PDE8 are cAMP-specific. The remaining PDE families are capable of degrading both cGMP and cAMP.6–9

The idea of targets at cGMP signaling pathway for treatment of DM originated from an early study that the cGMP-inhibited PDE (PDE3) played a critical role in the antilipolytic action of insulin.10 Later, PDE3B was shown to mediate the inhibition of lipolysis by proinsulin C-peptide in diabetic rat adipose tissue11 and to play an important role in acquisition of brown fat characteristics by white adipose tissue in male mice.12 In addition, PDE5 inhibitors enhanced muscle microvascular blood flow and glucose uptake response to insulin13 and improved dysfunction of metabolic and inflammatory processes in diabetic nephropathy.14 Moreover, inhibition of PDE10A has been recently shown to protect mice from diet-induced obesity and insulin resistance.15 For the highest affinity of cGMP with PDE9,6 several PDE9 inhibitors were patented for the potential treatment of diabetes and cardiovascular diseases in early years.16–20 After publication of the first PDE9 selective inhibitor BAY73-6691,21 highly potent PDE9A inhibitors such as PF-04447943,22 PF-4181366,23 and 28s24 have been reported (Figure 1). However, interest in PDE9 inhibitors has shifted to their applications to CNS diseases such as Alzheimer’s disease.25–31 The most potent compound, PF-04447943, completed its phase II clinical trial for the treatment of mild Alzheimer’s disease in April 2013.

Received: June 1, 2014
Published: November 28, 2014
Our initial effort on structure-based inhibitor design led to the discovery of compound 28s that uniquely forms a hydrogen bond with Tyr424 and has high affinity with PDE9A (IC$_{50}$ = 21 nM) and good selectivity over other PDEs.$^{24}$ In this paper, we report an improved compound 3r that has IC$_{50}$ = 0.6 nM against PDE9A and at least 150-fold selectivity over other PDEs.

The crystal structure of PDE9A-3r reveals significant differences in conformation and hydrogen bonding pattern between 3r from 28s. A cell-based assay shows that 3r inhibits the mRNA expression of phosphoenolpyruvate carboxykinase (PEPCK) and glucose 6-phosphatase (G-6-Pase), implying its potential as a hypoglycemic agent.

### RESULTS

#### Design of New PDE9A Inhibitors

We have previously reported a potent PDE9 inhibitor 28s that has an IC$_{50}$ of 21 nM against PDE9A and an 860-fold selectivity over PDE1B.$^{24}$ This compound directly forms a hydrogen bond with Tyr424 that is unique for PDE9 and PDE8 (phenylalanine in other PDE families) and may significantly contribute to selective binding of 28s to PDE9 over other PDE families. However, since 28s contains an $\alpha$-Ala block (Figure 1) that is predicted to be sensitive to stomach proteases, its in vivo stability would be a potential problem. Thus, we chose the pyrazolopyrimidinone ring of 28s as the scaffold and took the crystal structure of PDE9-28s$^{24}$ as the template to design new PDE9 inhibitors, in hopes of improvement on binding affinity and in vivo stability. Specifically, substitutions at the R$_1$ and R$_3$ positions and enantiomers at the R$_2$ position of 28s (Scheme 1) were optimized to obtain stable and potent PDE9 inhibitors.

#### Structure–Activity Relationships

For the substitution at the R$_1$ position, the cyclopentyl group had better affinity for PDE9A than the isopropyl, isobutyl, or chlorophenyl group, as shown by the IC$_{50}$ values of 3r (0.6 nM), 6r (1.0 nM), 7r (17.6 nM), and 28r (6.4 nM, Table 1). For the R$_2$ substitution, the methyl group was better than both hydrogen (28r/28s $\sim$ 1, 3r/3s $\sim$ 2, 6r $\sim$ 5, Table 1) and the isobutyl group (3r/3s $\sim$ 4r). The replacement of the methoxyl group with fluorine at the R$_3$ position produced similar affinity of the inhibitors against PDE9 ($3r \sim 8r$). Among the studied compounds, 3r showed the best potency with an IC$_{50}$ of 0.6 nM against the PDE9A catalytic domain (Table 1), which is 35-fold better than 28s. This affinity improvement appears to be dominantly contributed by the replacement of chlorophenyl ring of 28s with cyclopentyl group of 3r.

The (R)-enantiomers of 28r and 3r showed 3- to 5-fold better affinity with PDE9 than their (S)-enantiomeric counterparts (Table 1). This result agrees with the early report that the (R)-enantiomer of BAY73-6691 has about 4-fold better affinity than its (S)-enantiomer.$^{32}$ Explanation of this consistency is not clear, but it might mean that the binding pocket of PDE9 has a special shape for better fitting of the (R)-enantiomers than the (S)-enantiomers.

To investigate (R)/(S)-enantiomers’ impact on selectivity, inhibitions of both (R)/(S)-enantiomers of 3 and 28 were assayed against other PDE families (Table 2). Overall, all four compounds of 3 and 28 predominantly inhibit PDE9 with...
moderate selectivity over PDE5A1 (22- to 150-fold, Table 2). (R)-Enantiomers of 3r and 28r showed better affinity than their (S)-enantiomers against PDE1B2, PDE5A1, PDE7A1, and PDE10A2, but no consistent trend was observed for PDE4D2 (Table 2). Both enantiomers of 3 and 28 barely inhibit PDE8 (IC₅₀ of ∼100 μM, Table 2), which also contains a tyrosine at the corresponding position of Tyr424 of PDE9A2, implying that the inhibitory selectivity is jointly determined by multiple residues at the active sites of the PDE families.

We further tested the impact of the substitutions and enantiomers on the plasma protein binding (PPB) to see how much of the inhibitors are freely available for their binding to PDE9. The PPB assay was conducted using human plasma for compounds 3r, 3s, and 28s at concentrations of 1 and 5 μM (Supporting Information S1). In short, these compounds strongly interact with plasma proteins, as shown by the bound percentage of >94.3%. The enantiomers and substitutions at the R₁ position do not significantly impact the binding of these compounds to plasma proteins. Although a large percentile for plasma protein binding implies reduced availability of inhibitors for their targets,34 remaining free 3r in blood plasma might be sufficient for blocking the PDE9-cGMP signaling because of its high affinity with PDE9 (IC₅₀ of 0.6 nM).

**Binding of 3r to PDE9.** The X-ray structure of PDE9-3r, which was prepared by soaking of the PDE9-IBMX crystal in 2 mM 3r, shows definite 3r binding to the active site of PDE9A2 (Figure 2). The electron density in (2Fₒ − Fₑ) and (Fₒ − Fₑ) maps clearly revealed the unique conformation of 3r. The pyrazolopyrimidinone ring of 3r forms two hydrogen

Figure 2. Binding of 3r to PDE9A. (A) Surface presentation of the 3r binding to the active site pocket of PDE9A2. Atoms of carbon, nitrogen, and oxygen of PDE9A are presented in colors of white, blue, and red, respectively. Inhibitor 3r is shown as yellow sticks. Dotted lines represent hydrogen bonds. The blue mesh is the electron density of the difference (Fo − Fc) map that was calculated from the structure with omission of 3r and contoured at 3σ.

Figure 3. Comparison on binding of several PDE9 inhibitors. (A) Superposition between the crystal structures of PDE9-3r (yellow sticks) and PDE9-28s (cyan). PDE9 is presented in the surface mode. (B) Superposition between the crystal structures of PDE9-3r (cyan and yellow sticks) and PDE9-(R)-BAY73-6691 (salmon and green sticks).

However, the tails of 3r and 28s show significantly different conformations and interactions (Figure 3), although they have the similar chemical components and occupy the same locations. The replacement of the L-Ala block of 28s by a D-Ala unit of 3r causes significant changes of hydrogen-bonding pattern. Tyr424 forms a hydrogen bond with the amide oxygen of L-Ala of 28s in the structure of PDE9-28s34 but switches to the nitrogen adjacent to D-Ala of 3r (Figure 3A). Interestingly, the nitrogen atom of D-Ala of 3r forms a hydrogen bond (2.9 Å) with the carbonyl oxygen of Ala452, in contrast to the very weak contact (4.0 Å) in the PDE9-28s structure. This difference in hydrogen bond pattern might explain the 35-fold better affinity of 3r than 28s.

Significant Improvement of the in Vivo Properties of 3r over 28s. A preliminary pharmacokinetic analysis revealed that 3r has Cmax of 217 ng/mL, bioavailability of 9.8%, and T1/2 of 1.7 h in the oral administration mode (Table 3). These parameters show a significant improvement over those of 28s (Cmax of 16 ng/mL, T1/2 of 0.3 h, and bioavailability of 1.3%). The pharmacokinetic parameters of 3r from the intravenous administration, such as C0 = 24 mg/L and T1/2 = 5.3 h (Table 3), appear to be promising, but further studies are required for usability of 3r in intravenous administration mode. On the other hand, 8r shows reasonable pharmacokinetic properties of 18% bioavailability and T1/2 of 4.1 h in the oral administration mode (Table 3).

To further characterize properties of the compounds, solubility of 3r, 3s, and 28s was measured in simulated gastric/intestinal fluids. All the three compounds were more soluble in the simulated intestinal fluid (31, 31, and 13 µg/mL at pH 6.8 for 3r, 3s, and 28s) than in the simulated gastric fluid (26, 23, and 8 µg/mL at pH 1.4, Table 4). Comparable solubility of 3r and 3s in the simulated gastric and intestinal fluids implies no strong effect of the chirality on the solubility. However, the replacement of the chloral-phenyl group of 28s by the cyclic pentanyl ring of 3r (Figure 1), which is the only chemical difference between 3r/3s and 28s, appears to significantly contribute to the solubility.

The solubility data imply that the moderate 9.8% bioavailability of 3r may be due to its metabolic instability. Thus, we test the 3r stability in the mouse liver microsomes. The results showed that 3r was not very stable in the mouse liver microsomes, as shown by T1/2 of 23 min and E0 of 73% (Table 5). However, 3r is significantly better than the positive control

*Dose: 5 mg/kg. po = oral administration. iv = intravenous administration.*
compounds of testosterone and propranolol, which have $T_{1/2}$ of $\sim 2$ min and $E_{ih}$ of $\sim 97\%$ (Table 5).

**Inhibitor 3r Does Not Show Acute Toxicity.** Compound 3r was evaluated for acute toxicity. Twenty-four mice were randomly divided into three groups and given in single oral doses of 0, 600, or 1200 mg/kg 3r on the first day. The animals treated with 3r did not show any poisoned symptoms and mortality immediately or during the post-treatment period of 2 weeks. In addition, no abnormal behaviors and significant changes of water/food consumption and body weight were observed during the period of the experiments. Therefore, 3r was well tolerated up to a dose of 1200 mg/kg and has no acute toxicity.

**Inhibition on mRNA Expression of PEPCK and G-6-Pase in HepG2 Cell by 3r.** Upon stimulation by 8-Br-cAMP/dexamethasone, the mRNA expression of two key hepatic gluconeogenic genes of the HepG2 cell, PEPCK and G-6-Pase, was enhanced respectively by 233% and 194% relative to the basal level of the mRNA expression (Figure 4). As a positive control, 300 nM insulin reduced the mRNA expression of PEPCK and G-6-Pase to the basal level in HepG2 cell in the presence of stimulation of cAMP/dexamethasone. As shown in Figure 4, 3r at 10 nM sufficiently reduced the 8-Br-cAMP/dexamethasone-induced expression of PEPCK and G-6-Pase back to the basal level in HepG2 cells, implying that our inhibitor 3r is a potential hypoglycemic agent.

**DISCUSSION**

**Hints for Improvement of PDE9 Inhibitors.** Compound 28s effectively inhibits PDE9 at enzymatic level, but its in vivo stability needs to be improved. Although the cause of instability is not clear, three weak chemical links in 28s are possibly the candidates: the amide bond of the L-Ala unit, the methoxyl group, and the N-link between nitrogen and pyrazolopyrimidinone (Figure 1). The L-Ala unit appears to be mostly unstable and would be easily hydrolyzed by stomach proteases. Because d-amino acids are in general more stable than l-amino acids in stomach, the replacement of L-Ala with D-Ala may be a major factor for the prolonged $T_{1/2}$ values (0.85, 1.7, and 4.1 h for 28s, 3r, and 8r in the oral administration mode and 0.32, 5.34, and 1.01 h for 28s, 3r, and 8r in the intravenous administration mode, Table 3 and unpublished data for 28s). The longer $T_{1/2}$ value of 8r ($4.1$ h) than 3r ($1.7$ h) in the po mode might imply slower absorption of 8r by intestinal. However, the shorter $T_{1/2}$ value of 8r ($\sim 1$ h) than 3r ($\sim 5$ h) in the iv mode might imply that 8r is unstable and decomposable in liver. In short, the explanation of the data of metabolic stability and bioavailability could not be firmly concluded, and further improvement of the compounds is desirable.

The crystal structure of PDE9-3r shows that the methyl side chain of D-Ala of 3r points toward a hydrophobic subpocket that is composed of Leu420, Leu421, Phe441, Ala452, and Val457 (Figure 3A). This, however, is not a stereo-obstacle to protect the N-link and amide bond of the compounds from decomposition in vivo by live enzymes. Following this assumption, compound 4r that contains D-isoleucine in the place of D-Ala of 3r was synthesized.

"Testosterone, propranolol, and warfarin are the positive controls."
Unfortunately, the enzymatic assay shows slightly reduced potency of 4r (IC_{50} = 8.1 nM) in comparison to 0.6 nM of 3r. A molecular docking suggests that 4r binds to PDE9 in a similar pattern to 3r with slight position shift of the whole molecule, but the side chain of d-Leu did not penetrate into the small hydrophobic pocket. It remains to be elucidated if d-Leu could serve as a stereo-obstacle so as to improve the in vivo stability and if other replacements such as a straight propanyl group could penetrate the hydrophobic pocket and thus improve the affinity and stability.

**CONCLUSION**

Our structure-based design led to discovery of a PDE9 selective inhibitor 3r that is capable of inhibiting the mRNA expression of PEPCK and F-6-Pase and thus a potential hypoglycemic agent.

**EXPERIMENTAL SECTION**

**Molecular Docking.** Hydrogen atoms and charges were added to the PDE9A structure (PDB entry code 4G6E) by using the CHARMM force field and the Momany–Rone partial charge method as implemented in Accelrys Discovery Studio 2.5.S. All ionizable residues in the systems were set to their protonation states at a neutral pH. The zinc and magnesium ions were assigned with a charge of +2. Ligand 28a was used to define the active site of PDE9A and test docking by the CDocker Software and LigandFit protocols disclosed in Accelrys Discovery Studio 2.5.S. The radius of the input sphere was set as 10 Å from the center of the binding site, and the rest of the docking parameters were defined using the default values. Fifty random conformations were generated and optimized for each ligand. The output poses from docking were evaluated by the score of the program and also by visual inspection.

**Syntheses.** 1H NMR and 13C NMR spectra were recorded at room temperature on a Mercury-Plus 300 instrument or a Bruker AVANCE III 400 instrument with TMS as an internal reference. LC/MS was run on a LCMS-2010A. Thin-layer chromatography was performed on precoated silica gel F-254 plates (0.25 mm, E. Merck). Elemental analyses were carried out with a Vario EL series analyzer. Melting points were determined on a WRS-1B digital melting point apparatus and were not calibrated. IR spectra were recorded on a Thermo 330 FT-IR. All starting materials and reagents were purchased from commercial suppliers and used directly without further purification.

The syntheses of M0 and 28a were previously reported. Syntheses of intermediates M1–M3 and compounds 28a and 1–8r are shortly described as follows. The pyrazolopyrimidinones (M1–M3) and 2-amino-N-phenylacetamide derivatives with R0 and R1 substitutions (Scheme 1) were synthesized by the similar protocols in literature. Briefly, to a 10 mL of sealed vial were added i-PrOH (3 mL), pyrazolopyrimidinones (0.5 mmol), 2-amino-N-phenylacetamide derivatives (1.0 mmol), and Et3N (1.5 mmol). The reaction mixture was stirred in an oil bath preheated to 90 °C. After completion of the reaction as indicated by TLC, the reaction mixture was cooled to room temperature and concentrated in vacuo. The residue was purified by flash column chromatography on silica gel (eluted with DCM/MeOH = 25:1) to the targeted compounds. The following are the characterization of the compounds. The data of elemental analysis for all the new compounds are provided in the Supporting Information S2.

6-Chloro-1-isopropyl-1H-pyrazolo[3,4-d]pyrimidin-4-ol (M1) White solid, yield, 80%. Mp: 216–217 °C (95% MeOH). 

(3r) 6-Chloro-1-isopropyl-1H-pyrazolo[3,4-d]pyrimidin-4-ol (M1). 6-Chloro-1-isopropyl-1H-pyrazolo[3,4-d]pyrimidin-4-ol (M1). White solid, yield, 80%. Mp: 216–217 °C (95% MeOH). 

(3r) 6-Chloro-1-isopropyl-1H-pyrazolo[3,4-d]pyrimidin-4-ol (M1). 6-Chloro-1-isopropyl-1H-pyrazolo[3,4-d]pyrimidin-4-ol (M1). White solid, yield, 80%. Mp: 216–217 °C (95% MeOH).
(R)-2-(((Cyclopropyl-4-oxo-4,5-dihydro-1H-pyrazolo[3,4-d]pyrimidin-6-yl)amino)-N-(4-methoxyphenyl)-4-methylpentanamidine (4R). White solid, yield, 52%. Mp: 118–120 °C. MS (ESI), m/z: 439 ([M + H]+). H NMR (400 MHz, CDCl3) δ (ppm) 10.67 (s, 1H), 8.65 (s, 1H), 7.77 (s, 1H), 7.39 (d, J = 6.3 Hz, 2H), 6.77 (d, J = 6.8 Hz, 2H), 4.90 (s, 1H), 4.64 (s, 1H), 3.71 (s, 3H), 2.12 (1H), 0.91 (s, 6H). 13C NMR (101 MHz, CDCl3) δ (ppm) 171.0, 160.0, 156.7, 153.5, 152.4, 134.0, 130.4, 122.0, 114.1, 100.3, 31.5, 54.2, 54.1. IR (ATR, cm−1): 3425, 2927, 2850, 1678, 1608, 1543, 1453, 1345, 1121, 1042, 932, 781, 753. Purity >99.5%.

Cytoskeletal Assay. The PDE9A2 catalytic domains were solubilized from the PDE9A2 cationic model by using 6 M urea and purified using immobilized metal affinity chromatography (IMAC) on Ni2+ agarose. The PDE9A2 catalytic domains were then loaded onto a Resource HiLoad 16/60 superdex 200 column (GE Healthcare) and further purified by HiPrep 16/60 Sephadex G-25 desalting columns (GE Healthcare). The final solution was dialyzed into 50 mM Tris-HCl, pH 8.0, 100 mM MgCl2, and 1 mM EDTA.

Protein Expression and Purification. The PDE9A2 catalytic domain purified using IMAC was loaded onto a HiPrep 16/60 Sephadex G-25 desalting column. The final solution was dialyzed into 50 mM Tris-HCl, pH 8.0, 100 mM MgCl2, and 1 mM EDTA.

Cell-Based Assay for Inhibition on the mRNA Expression of PEPPK and G-6-Pase. The cell-based assay was performed following the protocols described in literature.

Table 6. Statistics on Diffraction Data and Structure Refinement

| Parameter | PDE9 3r |
|-----------|---------|
| Space group | P43212 |
| Unit cell, a (Å) | 103.6 (3.1) |
| Resolution (Å) | 1.2 |
| Completeness (%) | 91.5 (71.8)% |
| Average 1/σReflections | 0.065 (0.258) |
| Structure Refinement | |
| R-factor | 0.241 |
| Rmerge | 0.268 |
| Resolution (Å) | 3.0–2.0 |
| Reflections | 91 122 |
| Rmerge | 0.241 |
| Reflections | 23.0 (3.1) |
| Average B-factor (Å²) | 36.8 (5306) |
| Protein | |
| Inhibitor 3r | |
| Zn | 31.2 (38) |
| Mg | 40.0 (ε) |
| Water | 28.6 (ε) |
| “The numbers in parentheses are for the highest resolution shell. The number of reflections omitted for calculation of Rmerge.” The number of atoms in the crystallographic asymmetric unit. | |

Table 6 continued...
serum at 37 °C in 5% CO₂ overnight and then grown in the absence of serum for starvation overnight. After starvation, 1 μM dexamethasone (20 mM stock in 100% DMSO) and 0.5 mM 8-Br-cAMP (100 mM stock in water) were added and further incubated for 30 h. Various concentrations of PDE9 inhibitor 3τ were then added into the culture medium and incubated for 12 h. The mRNAs were extracted from the treated HepG2 cell with Ultrapure RNA kit. The genes of G-6-Pase and PEPCK were instantly synthesized by addition of 100 ng of cDNA and detected by qPCR.

Pharmacokinetics Analysis. Pharmacokinetic properties of 3τ and 8τ were analyzed by HD Biosciences and Medicilon Companies, Shanghai, China. Fifteen male CD-1 mice that are 5 weeks old and have body weight of 17–20 g (Shanghai Laboratory Animal Center, China) were used for the pharmacokinetic experiments of 3τ. Six male SD rats with body weight of 230–260 g were purchased from Shanghai SIPPR-BK LAB Animal Ltd., Shanghai, China, and used for the pharmacokinetic analysis of 8τ. Compound 3τ was dissolved/suspended in 5% DMSO, 10% Cremophor, and 85% saline for intravenous administration (iv) and in 5% DMSO and 95% (26% SBE-β-CD) for oral administration (po). Compounds 28s and 8τ were formulated in 10% DMSO plus 40% HP-β-CD and 5% DMSO/95% (20% HP-β-CD) for the po and iv administrations. A final dosage of 5 mg/kg mouse/rat of the formulated compounds was administered, and the blood samples were taken at various time points in 24 h. The concentration of the compounds in blood was analyzed by LC–MS/MS (Shimadzu liquid chromatographic system and API4000 mass spectrometer, Applied Biosystems, Ontario, Canada).

Solubility of PDE9A Inhibitors in Simulated Gastric/Intestinal Fluids. The simulated gastric fluid was prepared by dissolving 1 g of pepsin (Aladdin) into diluted hydrochloric acid, pH 1.4. The simulated intestinal fluid was prepared by dissolving 1 g of trypsin (Aladdin) into a solution of KH₂PO₄, pH 6.8. Compounds 3τ, 8τ, and 28s were dissolved in acetonitrile (HPLC-grade, Honeywell Burdick & Jackson) and mixed with the internal standard 1,3-dimethyl-5-fluorouracil (Sigma) to generate the standard curve. The excess compounds 3τ, 8τ, and 28s were incubated with the simulated gastric/intestinal fluids (4 mL) for 24–48 h at 37 °C. After 24–48 h, the samples were passed through 0.22 μm filter (Millipore) and then loaded to the HPLC system. HPLC experiments were performed in a Shimadzu LC-20AT HPLC system, and wavelength of 254 nm was used for detection. A Thermo Hypersil MOS-2 C8 column (150 mm × 4.6 mm, 5 μm) was run at 37 °C with a mobile phase of 0.1% aqueous formic acid and 0.1% formic acid acetonitrile (60:40%, v/v) at flow rate of 1.0 mL/min. The retention time and peak area were determined for each compound. The average peak areas from the triplicate measurements were compared with the standard curve to calculate the mean solubility.

Stability of 3τ in the Mouse Liver Microsome. CD-1 mouse liver microsome was purchased from BD Gentest Corporation (Woburn, MA, USA). Compound 3τ was dissolved in 100% DMSO as 10 mM stock solution and diluted to a final concentration of 0.5 μM for the experiments. Warfarin (Sigma, St. Louis, MO, USA), testosterone (Acros, Belgium), and propranolol (TRC, Toronto, Canada) were used as the positive controls. Liver microsome incubations were conducted in duplicate in 96-well plates. Each well contains 30 μL of 0.1 M potassium phosphate buffer (pH 7.4), 3.0 mM MgCl₂, 0.75 mg/mL mouse liver microsome, and 0.75 μM 3τ or the positive controls. After 5 min of preincubation at 37 °C, 15 μL of 3 mM NADPH in 0.1 M potassium phosphate buffer was added to initiate the enzymatic reaction. Reactions were terminated at various time points (0, 5, 10, 20, 30 min) by adding 90 μL of ice-cold acetonitrile containing internal standard. A parallel incubation was performed using 0.1 M potassium phosphate buffer (pH 7.4) as the negative control, and reactions were terminated after 30 min incubation. A Shimadzu liquid chromatographic system and an API4000 mass spectrometer equipped with Turbo Ion Spray (ESI) interface ( Applied Biosystems, Concord, Ontario, Canada) were used for detection. Analyst 1.5 software packages (Applied Biosystems) were used for control of the LC–MS/MS system, as well as data acquisition and processing.

Acute Toxicity of 3τ. The acute toxicity was tested following the similar protocols described in our previous study.²⁰ Twenty-four KM mice (22 days, 18–20 g), purchased from the Laboratory Animal Center of Sun Yat-Sen University (Guangzhou, China), were used to evaluate the acute toxicity of 3τ. Mice were randomly divided into three groups, each of which was given in single oral dose of 0, 600, or 1200 mg/kg 3τ on the first day of the experiment. Mice were maintained on a 12 h light/dark cycle (light from 7:00 to 19:00) at room temperature and 60–70% relative humidity. Sterile food and water were given according to the institutional guidelines. Prior to each experiment, mice were fasted overnight and allowed free access to water. Compound 3τ was dissolved in 5% DMSO and 95% (26% SBE-β-CD) solution and orally administrated. Mice were observed for any abnormal behavior and mortality and weighed at the fourth hour of administration and then every 24 h for 14 days. Animals were sacrificed on the 14th day, and tissue samples of heart, liver, and kidney were macroscopically examined for possible damages.
