Abstract
In our companion papers, we managed to derive a connection formulation of Lorentzian general relativity in $D + 1$ dimensions with compact gauge group $\text{SO}(D + 1)$ such that the connection is Poisson-commuting, which implies that loop quantum gravity quantization methods apply. We also provided the coupling to standard matter. In this paper, we extend our methods to derive a connection formulation of a large class of Lorentzian signature supergravity theories, in particular 11D SUGRA and 4D, $N = 8$ SUGRA, which was in fact the motivation to consider higher dimensions. Starting from a Hamiltonian formulation in the time gauge which yields a Spin($D$) theory, a major challenge is to extend the internal gauge group to Spin($D + 1$) in the presence of the Rarita–Schwinger field. This is non-trivial because SUSY typically requires the Rarita–Schwinger field to be a Majorana fermion for the Lorentzian Clifford algebra and Majorana representations of the Clifford algebra are not available in the same spacetime dimension for both Lorentzian and Euclidean signatures. We resolve the arising tension and provide a background-independent representation of the non-trivial Dirac antibracket $^*$-algebra for the Majorana field which significantly differs from the analogous construction for Dirac fields already available in the literature.

Note that choice (0.11) is always possible [1]. Furthermore, note that in a Majorana representation, the spinors will be real and then, from the Majorana condition (0.18) \( \gamma^0 = C \) follows.

1. Introduction

Over the years after the discovery of \( D + 1 = 3 + 1 \) supergravity by Freedman, Ferrara and van Nieuwenhuizen in 1976 [2], there has been a lot of activity in the newly formed field of supergravity, driven by the hope to construct a theory of quantum gravity without the shortcoming of perturbative non-renormalizability. Nahm classified in 1977 all possible supergravities, arriving at the result that, under certain assumptions, \( d = 11 \) was the maximal number of Minkowski signature spacetime dimensions in which supergravities could exist [3]. In the following year, \( d = 11 \) supergravity was constructed by Cremmer, Julia and Scherk [4] in order to obtain \( d = 4, N = 8 \) maximal supergravity by dimensional reduction. Various forms of supergravity were derived in dimensions \( d \leq 11 \) and relations among them were discovered in the subsequent years [5].

While the initial hope linked with perturbative supergravity was vanishing due to results suggesting its non-renormalizability [6] and the community turned to superstring theory, a new candidate theory for quantum gravity, loop quantum gravity (LQG), started to emerge after Ashtekar discovered his new variables in 1986 [7]. Over the next 10 years, the initially
complex variables were cast into a real form by Barbero [8], rigorous techniques for the construction of a Hilbert space were developed [9–14] and a representation of the constraint operators on the Hilbert space was defined [15]. The strengths of the theory are, among others, its entirely non-perturbative and background-independent formulation as well as the suggested appearance of a quantum geometry at the Planck scale. It is therefore in a sense dual to the perturbative descriptions coming from conventional quantum (super)gravities and superstring-/M-theory and it would be very interesting to compare and merge the results coming from these two different approaches to quantum gravity. The main conceptual obstacle in comparing these two methods of quantization has been the spacetime they are formulated in. While the Ashtekar–Barbero variables are only defined in $3 + 1$ dimensions, where also an extension to supersymmetry exists, superstring-/M-theory favours $9 + 1/10 + 1$ dimensions and is regarded as a quantization of the respective supergravities. It is therefore interesting to study quantum supergravity as a means of probing the low-energy limit of superstring/M-theory with different quantization techniques, both perturbative and non-perturbative. A somewhat different approach has been taken in [16], where the closed bosonic string has been quantized using rigorous background-independent techniques, resulting in a new solution of the representation problem which differs from standard String theory. Also, the Hamiltonian formulation of the algebraic first-order bosonic string and its relation to self-dual gravity have recently been investigated in [17, 18].

Apart from contact with superstring-/M-theory, new results from perturbative $d = 4, N = 8$ supergravity [19–21] suggest that the theory might be renormalizable, contrary to prior believes. It is therefore interesting in its own right to study the loop-quantized $d = 4, N = 8$ theory and compare the results with the perturbative expansion.

The main obstacle in the connection formulation of general relativity with or without SUSY is represented by the gravitational variables. Starting from the plain Einstein–Hilbert term in a (super)gravity action, one obtains the ADM variables $q_{ab}$ and $P_{ab}$ [22]. In order to incorporate fermions, it is mandatory to use tetrads and their higher dimensional analogues (vielbeins) to construct a representation of the curved spacetime Dirac (Clifford) algebra. At this point, it is convenient to use the time gauge [23] to obtain a densitized $D$-bein $E_a^i$ and its canonically conjugate momentum $K_a^i$ as canonical variables. Since the time gauge fixes the boost part of the internal gauge group $SO(1, D)$, we are left with a $SO(D)$ gauge theory. The problem however is that the Gauß constraint generating the internal rotations transforms $E_a^i$ and $K_a^i$ as internal vectors, and thus not as a connection and a vector. It was shown in [24, 25] that starting from this formulation, one can construct a canonical transformation which leads to a formulation in terms of a $SO(D + 1)$ connection $A_{aIJ}$ and its canonically conjugate momentum $\pi^{aIJ}$, where it was necessary to enlarge the dimension of the internal space by one space-like dimension.

The purpose of this paper is to generalize this transformation to supergravity theories. The problems arising in these generalizations are not so much linked to the appearance of additional tensor fields and spin-$1/2$ fermions, but to the Rarita–Schwinger field which obeys a Majorana condition. It is well known [26] that in order to have simple and metric-independent Poisson brackets for the Rarita–Schwinger field $\psi_a^\alpha$, one should use half-densitized internally projected fields $\phi_a^\alpha := \sqrt{q}e_a^i\psi_i^\alpha$. This field redefinition has to be changed in order to work in the new internal space; more specifically, we have to ensure that the number of degrees of freedom still matches by imposing suitable constraints. Also, the Majorana conditions are sensitive to the dimensionality and signature of spacetime. We thus have to ensure that no inconsistencies arise when using $SO(D + 1)$ instead of $SO(1, D)$ as the internal gauge group. Concretely, this will be achieved in dimensions where Majorana representation for the $\gamma$-matrices exists, which covers many interesting supergravity theories ($d = 4, 8, 9, 10, 11$).
The presence of additional tensors, vectors, scalars and spin-1/2 fermions in various SUGRA theories does not pose any problems for this classical canonical transformation. However, we must provide background-independent representations for these fields in the quantum theory which, to the best of our knowledge, has not been done yet for all of them. As an example, in our companion paper [27] we consider the quantization of Abelian p-form fields such as the three-index photon present in 11 D SUGRA with Chern–Simons term. Scalars, fermions and connections of compact, possibly non-Abelian, gauge groups have already been treated in [28].

The paper is organized as follows.

Section 2 is subdivided into two parts. In the first part, we review prior work on canonical supergravity theories in various dimensions and identify their common structural elements. We also mention the basic difficulties in our goal to match these canonical formulations to the reformulations [24, 29] of the graviton sector. In the second part, we display canonical supergravity explicitly in the time gauge paying special attention to the Rarita–Schwinger sector.

Section 3 is also subdivided into two parts. In the first one, we display the symplectic structure of the Rarita–Schwinger field in the time gauge in convenient variables which will be crucial for a later quantization of the theory. In the second one, following the strategy in [24, 25] we perform an extension of the phase space subject to additional second-class constraints ensuring that we are dealing with the same theory while the internal gauge group can be extended from SO(D) to SO(D + 1).

In section 4, we construct a representation of the Dirac antibracket geared to Majorana spinor fields rather than Dirac spinor fields.

In section 5, we show that our formalism easily extends without additional complications to chiral supergravities (Majorana–Weyl spinors) and to spin-1/2 Majorana fields which are present in some supergravity theories.

In section 6, we summarize and conclude.

Finally, in the appendix, we supply the details of the formulation of higher dimensional connection general relativity with linear simplicity constraints in terms of a normal field $N^I$ which is convenient in order to resolve the aforementioned tension between SO(1, D) and SO(D + 1) Majorana spinors and we provide a Hilbert space representation of the normal field sector.

2. Review of canonical supergravity

In the first part of this section, we summarize the status of canonical supergravity and its quantization. In the second one, we display the details of the theory to the extent we need it which will settle the notation.

2.1. Status of canonical supergravity

Hamiltonian formulations of supergravity are a tedious business due to the complexity of the Lagrangians and the appearance of constraints. Nevertheless, the canonical structure emerging is very similar for the explicitly known Hamiltonian formulations. To the best of our knowledge, the $D + 1$ split for $D \geq 3$ has been explicitly performed for $D + 1 = 3 + 1, N = 1$ [26, 30–32], $D + 1 = 9 + 1, N = 1$ [33] and $D + 1 = 10 + 1, N = 1$ [34]. The algebra of constraints of $D + 1 = 3 + 1$ supergravity was first computed by Henneaux [35] up to terms quadratic in the constraints [36]. The same method was applied by Diaz [37] to $D + 1 = 10 + 1$ supergravity, also neglecting terms quadratic in the constraints. Sawaguchi performed an explicit calculation of
the constraint algebra of $D + 1 = 3 + 1$ supergravity in [38] where a term quadratic in the Gauß constraint appears in the Poisson bracket of two supersymmetry constraints. The constraint algebra for $D + 1 = 9 + 1$, $N = 1$ supergravity coupled to supersymmetric Yang–Mills theory was calculated by de Azeredo Campos and Fisch in [39].

Shortly after the introduction of the complex Ashtekar variables, Jacobson generalized the construction to $d = 4$, $N = 1$ supergravity [40]. In the following, different authors including Fülöp [41], Gorobey and Lukyanenko [42], as well as Matschull [43], explored the subject further. Armand–Ugon, Gambini, Oblégon and Pullin [44] formulated the theory in terms of a GSU(2) connection and thus unified bosonic and fermionic variables in a single connection. Building on these works, Ling and Smolin published a series of papers on the subject [45–47], where, among other topics, supersymmetric spin networks coming from the GSU(2) connection were studied in detail. In the above works, complex Ashtekar variables are employed for which the methods developed in [9–14] are not available. Also, the Ashtekar variables are restricted to four spacetime dimensions and thus not applicable to higher dimensional supergravities. Aiming at a unification of String theory and LQG, Smolin explored non-perturbative formulations of certain parts of eleven-dimensional supergravity [48, 49]. The generalization of the loop quantum gravity methods to antisymmetric tensors was considered by Arias, di Bartolo, Fustero, Gambini and Trias [50]. The full canonical analysis of $d = 4$, $N = 1$ supergravity was first performed by Sawaguchi [38]. Kaul and Sengupta [51] considered a Lagrangian derivation of this formulation using the Nieh–Yan topological density.

An attempt to construct Ashtekar-type variables for $d = 11$ supergravity has already been made by Melosch and Nicolai using an SO(1, 2) × SO(16) invariant reformulation of the original CJS theory [52]. In this formulation, the connection is not Poisson-commuting thus forbidding LQG techniques. In a paper on canonical supergravity in $2 + 1$ dimensions [53], Matschull and Nicolai discovered a similar noncommutativity property which they avoided by adding a purely imaginary fermionic bilinear to the connection, leading to a complexified gauge group. As was observed in [28], this problem can be avoided by using half-densitized fermions as canonical variables.

The general picture emerging is that the canonical decomposition $S = \int dt (p_\gamma - H)$ in the time gauge leads to

\[
S = \int d^Dx \int dt \left( \dot{E}^a_\gamma K^a_\gamma + i\sqrt{q}\bar{\psi}_a \gamma^{a,\lambda}b_\lambda + \text{tensors} + \text{vectors} + \text{spin } 1/2 + \text{scalars} - N\mathcal{H} - N^a\mathcal{H}_a - \lambda_{ij}G^{ij} - \bar{\psi}_a S - \text{tensor constraints} \right),
\]

where the Hamiltonian constraint $\mathcal{H}$, the spatial diffeomorphism constraint $\mathcal{H}_a$, the Spin(D) Gauß constraint $G^{ij}$, the supersymmetry constraint $S$ and the tensor constraints form a first-class algebra. $E^a_\gamma$ is the densitized vielbein and $K^a_\gamma$ is its canonical momentum. $\bar{\psi}_a$ denotes the Rarita–Schwinger field with suppressed spinor indices. $N$, $N^a$, $\lambda_{ij}$ and $\bar{\psi}_a$ are Lagrange multipliers for the respective constraints. With tensor constraints we mean constraints acting only on additional tensor fields such as the three-index photon of $D + 1 = 10 + 1$ supergravity. The remaining terms in the first line are kinetic terms appearing in the decomposition of the action. Since we will not deal with them in this paper, we refer to [33, 34] for details.

In order to apply the techniques developed for loop quantum gravity to this system, we have to turn it into a connection formulation in the spirit of the Ashtekar variables. Concerning the purely gravitational part, this has been achieved in [24, 25] and extended to the case of spin-1/2 fermions in [25]. The Rarita–Schwinger field turns out to be more difficult to deal with than the spin-1/2 fermions. On the one hand, it leads to second-class constraints [31], which encode the reality conditions, with a structure which is different from the case of Dirac
spacetime dimensions, the relations we will continue with the general treatment in the next section. We remark that in 3 potential derived in this context is exemplary for the supergravity theories of our interest and canonical decomposition. The resulting picture generalizes to all dimensions. The symplectic formalism and the conventional canonical analysis is discussed in [62] using the example of four-dimensional supergravity coupled to supersymmetric Yang–Mills theory.

2.2. Canonical supergravity in the time gauge

We will illustrate the 3 + 1 split of N = 1 supergravity in first-order formulation as performed by Sawaguchi [38] in order to give the reader a feeling for what is happening during the canonical decomposition. The resulting picture generalizes to all dimensions. The symplectic potential derived in this context is exemplary for the supergravity theories of our interest and we will continue with the general treatment in the next section. We remark that in 3 + 1 spacetime dimensions, the relations C\(T\) = \(-C\) and \(C'y^{-1} = -(y')^T\) hold, where C denotes the charge conjugation matrix.

The action for 3 + 1, N = 1 first-order supergravity is given by

\[
S = \int_M d^4x \left( \frac{\sqrt{-g}}{2} \bar{\psi} \gamma^{\mu\nu\sigma\tau} \nabla_{\mu} \psi_{\nu} \right).
\] (2.2)

Using the conventions introduced above and \(\gamma^{\mu\nu\sigma\tau} = \gamma^{JIK}\epsilon_{I}\epsilon_{J}\epsilon_{K}\), one can explicitly check that the action is real. The 3 + 1 decomposition is done like in the previous papers, and the notation used can be found there (if not above). We obtain

\[
S = \int_M d^4x \left( \frac{\sqrt{-g}}{2} \bar{\psi} \gamma^{\mu\nu\sigma\tau} \nabla_{\mu} \psi_{\nu} \right)
\]

\[
= \int_R \int_\sigma d^3x \left[ \frac{1}{2} \pi_{\mu\nu} \mathcal{L}_T A_{\mu\nu} - i \sqrt{g} \bar{\psi}_a \gamma^{\mu\nu\sigma\tau} \nabla_{\mu} \psi_b - \mathcal{N}_{\text{grav}}(\mathcal{H}^\text{grav} - i \sqrt{g} \bar{\psi}_a \gamma^{\mu\nu\sigma\tau} \nabla_{\mu} \psi_b) \right]
\]

\[
= i \bar{\psi}_a (\sqrt{g} \gamma^{\mu\nu\sigma\tau} \nabla_{\mu} \psi_b) \psi_a + \sqrt{g} \nabla_{\mu} (\gamma^{\mu\nu\sigma\tau} \psi_b).
\] (2.3)

From there, one can read off the constraints \(\mathcal{H}, \mathcal{H}_a, G^{IJ}\) and \(S\). We will choose the time gauge \(n^I = \delta^I_0\) at this point to simplify the further discussion. For the symplectic potential, we find

\[
\int_R \int_\sigma d^3x \left( \frac{1}{2} \pi_{\mu\nu} \mathcal{L}_T A_{\mu\nu} - i \sqrt{g} \bar{\psi}_a \gamma^{\mu\nu\sigma\tau} \nabla_{\mu} \psi_b \right)
\]

\[
= \int_R \int_\sigma d^3x \left( \bar{E}^{\mu}_{\alpha} K_{\alpha} - i \phi_{\alpha} \gamma^{\beta\gamma} \phi_{\beta} \right)
\]

\[
= \int_R \int_\sigma d^3x \left( \bar{E}^{\mu}_{\alpha} K_{\alpha} - i \phi_{\alpha} \gamma^{\beta\gamma} \left( \phi_{\beta} - (\bar{E}^\gamma) E^\gamma_{\beta} \phi_{\beta} \right) \right)
\]

\[
= \int_R \int_\sigma d^3x \left( \bar{E}^{\mu}_{\alpha} K_{\alpha} - \pi j \left( \phi_{\beta} - (\bar{E}^\gamma) E^\gamma_{\beta} \phi_{\beta} \right) \right)
\]

3 While for Dirac spinors, the second-class constraints are of the form \(\pi_{\chi} \propto \psi, \pi_{\chi} \propto \bar{\psi},\) in the Majorana case, we obtain an equation of the form \(\pi_{\chi} \propto \psi,\) where \(\pi_{\chi}\) denotes the momenta conjugate to \(x.\)

\[
\begin{aligned}
&= \int R d^3x \left( \hat{H}^{al}(K_{al} + \pi_i E^i a) - \pi^1 \phi_1 \right) \\
&= \int R d^3x \left( \hat{H}^{al} K_{al} - \pi^1 \phi_1 \right),
\end{aligned}
\]

where we successively defined

\[
\phi_a := \sqrt{q} \psi_a, \quad \phi^i := \frac{1}{\sqrt{q}} E^i a, \quad \pi^i := i \phi^i \gamma^i \quad \text{and} \quad K'_{al} := K_{al} + \pi_i E^i a \phi_1.
\]

In the second line, we chose time gauge and half-densities as fermionic variables [28]. Then, we transformed the spatial index of the fermions into an internal one using the vielbein, but preserving the fermionic density weight [26]. This second transformation also affects the extrinsic curvature and we have to define a new variable \(K'_{al}\). The Gauß constraint becomes under these changes of variables

\[
G^{ij} = 2K_{[l}^i E^{a]j} - \pi^k [i \Sigma^{ij}] \phi_k
\]

\[
= 2(K_{a[l}^{[i} - \pi^k E^a_k \phi_k) E^{a]j} - \pi^k [i \Sigma^{ij}] \phi_k
\]

\[
= 2K_{[l}^i E^{a]j} - 2 \pi^k [l \phi] - \pi^k [i \Sigma^{ij}] \phi_k.
\]

The generator of spatial diffeomorphisms \(\mathcal{H}_a\) is given by the following linear combination of constraints:

\[
\mathcal{H}_a := \mathcal{H}_a + \frac{1}{2} \Lambda_{aj} G^{ij} + i \dot{\psi}_a S.
\]

It becomes

\[
\mathcal{H}_a = E^{b[j} \partial_b (K_{bij} - \partial_b (E^{b[i} K_{bij}) - \pi^b \partial_b \phi_0 + \partial_b (\pi^b \phi_0))
\]

\[
= E^{b[j} \partial_b (K_{bij} - \pi^b E^b \phi_0) - \partial_b (E^{b[i} (K_{bij}^i + \pi_j E^j \phi_0))
\]

\[
- \frac{1}{\sqrt{q}} \pi^b E^b \partial_b (\sqrt{q} \phi^b E_{bij}) + \partial_b (\pi^b E^{b[i} E^{j]}_{bij})
\]

\[
= E^{b[j} \partial_b (K_{bij} - \partial_b (E^{b[i} K_{bij}) + \sqrt{q} \partial_b (1 \sqrt{q} \pi^i)) \phi^j
\]

\[
= E^{b[j} \partial_b (K_{bij} - \partial_b (E^{b[i} K_{bij}) + \frac{1}{2} \partial_b (\pi^i) \phi^j - \frac{1}{2} \pi i \partial_b \phi^i.
\]

For the last step, note that \(\pi^i \phi = 0\). Thus, these constraints exactly change as one would expect under the performed change of variables. The other constraints can also be rewritten in terms of the new variables, but this is less instructive and their explicit form is not important for what follows. We want only to remark that they depend on the contorsion \(K_{al}\), which is not dynamical and has to be solved for in terms of \(\phi_i\). This can be done explicitly.

3. Phase space extension

In this section, we focus on the symplectic structure of the Rarita–Schwinger sector. In the time gauge, this is a SO(D) theory which is the subject of the first part. In the second part, we will perform a phase space extension to a SO(D + 1) theory where special attention must be paid to the reality conditions.

3.1. Symplectic structure in the SO(D) theory

The 3 + 1 split described above generalizes directly to higher dimensions. We will always impose the time gauge \(n^i = \delta^t_0\) prior to the \(D + 1\) split and restrict to dimensions where a
Majorana representation of the $\gamma$-matrices exists, which we will use. This allows us to set $C = \gamma^0$ which simplifies the following analysis. The generic terms important for this paper appearing in supergravity theories are

\[
S_{\text{grav} + RS} = \int_M d^{D+1}X \left( \frac{S}{2} e^{\mu} \epsilon^{ij} F_{\mu ij}(A) + ix e \bar{\psi}_\mu \gamma^{\mu \rho \sigma} \nabla_\rho (A) \psi_\sigma \right)
\]

in the case of a first-order formulation and analogous terms for a second-order formulation. This difference in defining the theory will not be important in what follows, since as demonstrated above for the $(3 + 1)$-dimensional case, the symplectic potential of these actions in the time gauge turns out to be

\[
\int_{\mathbb{R}} dt \int d^D x (-E^a L_T K_{ab} - i \sqrt{q} \bar{\psi}_a \gamma^{\perp i ab} L_T \psi_b) = \int_{\mathbb{R}} dt \int d^3 x (E^a K_{ab} - \pi^i \phi_j),
\]

where we used the same definitions as in (2.5). From (3.2) we can read off the non-vanishing Poisson brackets\(^4\)

\[
\{E^a, K_{ij}^b\} = \delta^a_i \delta^b_j \quad \text{and} \quad \{\phi^a_i, \pi^b_j\} = -\delta^a_j \delta^b_i.
\]

Additionally, we have the following second-class constraints and reality conditions:

\[
\Omega^i := \pi^i + i \phi^a_i C \gamma^0 \gamma^i = 0 \quad \text{and} \quad \phi^i_j = -\phi^i_j C \gamma^0.
\]

In order to be able to introduce a connection variable along the lines of [24], we need to enlarge the internal space, i.e. replacing the gauge group $SO(D)$ by either $SO(1, D)$ or $SO(D + 1)$. In view of subsequent quantization, $SO(D + 1)$ is favoured because of its compactness and will be our choice in the following. This enlargement can be done consistently if also additional spinorial degrees of freedom are added as well as additional constraints which remove the newly introduced fermions. Finally, the extension has to be consistent with the reality conditions. All this turns out to be rather hard to achieve, and the final version of the theory looks rather different from what a ‘first guess’ might have been. To motivate it, we will review the whole process of finding the theory, showing where the straightforward ideas lead to dead ends, and how they can be modified to arrive at a consistent theory. We will only discuss the fermionic variables; the gravitational part is treated in the appendix.

Before we enlarge the internal space, we will get rid of the second-class constraints. To this end, we calculate the Dirac matrix

\[
C^{ij} = \{\Omega^i, \Omega^j\} = -2iC \gamma^0 \gamma^{ij}, \quad (C^{-1})_{ij} = -\gamma^0 \frac{i}{2(D-1)}((2-D)\eta_{ij} + \gamma_{ij})C^{-1}.
\]

and thus find for the Dirac bracket

\[
\{\phi_i, \phi_j\}_{DB} = -\{\phi_i, \Omega^k\}(C^{-1})_{ki}(\Omega^l, \phi_j) = -(C^{-1})_{ij}.
\]

To simplify the subsequent discussion, in the following we will consider real representations of the Dirac matrices only, which implies $C = \gamma^0$. Then the above equations read

\[
C^{ij} = 2i\gamma^{ij}, \quad (C^{-1})_{ij} = -\frac{i}{2(D-1)}((2-D)\eta_{ij} + \gamma_{ij}), \quad \{\phi_i, \phi_j\}_{DB} = -(C^{-1})_{ij}.
\]

Now we can either (a) try to enlarge the internal space and afterwards choose new variables which have simpler brackets, or (b) we simplify the Dirac bracket before enlarging the internal space. (a) immediately leads to problems. The symmetry of the Poisson brackets

\[\text{More precisely, we should call them Poisson antibrackets which are symmetric under the exchange of the arguments and which are to be quantized by anticommutators. We will call them Poisson brackets anyway for notational simplicity in what follows with the usual rules for the interplay between the Poisson brackets for integral and half-integral spin, respectively. See e.g. [63, 64] for an account.}\]
\( \{ \phi^I, \phi^J \} \propto (C^{-1})_{IJI}^{\alpha\beta} \) implies that the matrix \( C^{-1} \) is symmetric under the exchange of \((I, \alpha) \leftrightarrow (J, \beta)\). The naive extension \((C^{-1})_{IJ} = -(2-D) \eta_{IJ} + \gamma_{IJ}\) however does not have this symmetry. Its symmetric part \( \tilde{C}^{-1} = (C^{-1})^{ij} \tilde{C}^{ji} \) is not invertible. Of course, one can extend \( C^{-1} \) in different, more ‘unnatural’ ways, e.g. containing terms like \( \gamma_j^I \gamma_I \) etc. and ‘cure’ this problem for a moment, but also the Gauß constraint will be problematic. The \( SO(D) \) constraint contains \( C^{ij} \) (since we used \( \pi^I = -\frac{1}{2} \phi^J C^{ij} \)) and this matrix should also be replaced by some \( \tilde{C}^{ij} \), such that \( \phi_i \) transforms covariantly and \( G_{ij} \) reduces correctly to \( G^{ij} \) if we choose time gauge and solve its boost part. This implies restrictions on \( C \) and further restrictions on \( \tilde{C}^{-1} \). We did not succeed in finding matrices which fulfil all these requirements. In the following, we therefore will follow the second route (b) and simplify the Dirac brackets before doing the enlargement of the internal space.

There are several possible ways of simplifying the Dirac brackets.

1. Note that the matrix \( C^{-1} \) on the right-hand side of the Dirac brackets is imaginary and symmetric; hence, there always exists a real, orthogonal matrix \( \Omega^I_j \) such that under the change of variables \( \phi^I \rightarrow \phi'^I := \Omega^I_j \phi^j \), the brackets become \( i \) times a real diagonal matrix. However, now the new fundamental degrees of freedom \( \phi'^I \) in general do not transform nicely under \( SO(D) \) gauge transformations, only \( (O^{-1})^T \phi^I \) do. More severely, it is unclear how the extension \( O^I_j \rightarrow \Omega^I_j \) should be done.

2. To assure that the fundamental degrees of freedom still transform nicely under \( SO(D) \) transformations, we can use the Ansatz \( \phi'^I := M^I_\nu \phi^\nu \) with \( M^I_\nu := (\alpha \delta^I_\nu + \beta \Sigma^I_\nu) \). Matrices of this form are in general invertible (cf point (3) below for two exceptions) and, since they are constructed from intertwining matrices, \( \phi'^I \) will transform nicely under gauge transformations. Moreover, now there is a chance to generalize the matrix to one dimension higher. For the Dirac brackets to become diagonal, \( \alpha \) and \( \beta \) have to be determined by solving \( M C^{-1} M^T = iI \). The problem is that there is no solution for both parameters being real, at least one is necessarily complex. More general Ansätze for \( M^I_\nu \) (e.g. involving \( \gamma_{\nu e} \) in even dimensions) share the same problem. Thus, we exchanged the problem of complicated brackets with complicated reality conditions, which again are hard to quantize.

3. The third route, which will lead to the consistent theory, in the end implies the introduction of additional fermionic degrees of freedom already before enlargement of the internal space. Given the difficulties just mentioned, the optimal approach in the desire to simplify the Poisson brackets is to find orthogonal projections onto subspaces of the real Graßmann vector space which are built from \( \delta_{ij} \) and \( \Sigma_{ij} \) such that the symplectic structure becomes block diagonal on those subspaces. One can then define simple Poisson brackets and add the projection constraints as secondary constraints which leads to corresponding Dirac brackets which will be proportional to those projectors. As we will see, the fact that these are projectors makes it possible to find a Hilbert space representation of the corresponding Dirac bracket.

We define in any dimension \( D \)

\[
\begin{align*}
\mathbb{P}^{ij}_{\alpha\beta} &:= \eta^{ij}\delta_{\alpha\beta} - \frac{1}{D} (\gamma^{i} \gamma^{j})_{\alpha\beta} = \frac{D-1}{D} \eta^{ij}\delta_{\alpha\beta} - \frac{2i}{D} \Sigma^{ij}_{\alpha\beta}, \\
\mathbb{Q}^{ij}_{\alpha\beta} &:= \frac{1}{D} (\gamma^{i} \gamma^{j})_{\alpha\beta} = \frac{1}{D} \eta^{ij}\delta_{\alpha\beta} + \frac{2i}{D} \Sigma^{ij}_{\alpha\beta}.
\end{align*}
\]  

Those matrices are both real (we are using Majorana representations) and built from intertwiners, but they are not invertible. It is easy to check that

\[
\mathbb{P}^{ij}_{\alpha\beta}\mathbb{Q}^{jk}_{\gamma\delta} = 0, \quad \mathbb{P}^{ij}_{\alpha\beta}\mathbb{P}^{jk}_{\gamma\delta} = \mathbb{P}^{ij}_{\alpha\beta}, \quad \mathbb{Q}^{ij}_{\alpha\beta}\mathbb{Q}^{jk}_{\gamma\delta} = \mathbb{Q}^{ij}_{\alpha\beta} \text{ and } \mathbb{P} + \mathbb{Q} = I \eta.
\]
When considering the free Rarita–Schwinger action, this decomposition also appears to isolate the physical degrees of freedom. Using these projectors, we can decompose the Rarita–Schwinger field as follows:

\[ \phi_i = P_{ij} \phi^j + Q_{ij} \phi^j =: \rho_i + \frac{1}{D} \gamma^i \sigma, \]

(3.11)

with \( \rho_i := P_{ij} \phi^j \) and \( \sigma := \gamma^i \phi^i \). Using the reality conditions (3.4) for \( \phi_i \), we find

\[ \bar{\rho}_i = \rho_i^T C \quad \text{and} \quad \bar{\sigma} = \sigma^T C. \]

(3.12)

Moreover, using

\[ \gamma^{ij} = -i \rho^{ij} + (D - 1) Q^{ij}, \]

(3.13)

the symplectic potential becomes

\[ -\pi^i \phi_i = -i \phi^i \gamma^{ij} \phi_j \]

\[ = -i \phi^i ( -P^i \mu + (D - 1) Q^{ij} ) \phi_j \]

\[ = -i \phi^i ( -P^i \mu + (D - 1) Q^{ij} Q_{ij}^k ) \phi_j \]

\[ = i (P_k^i \phi_j) (P_k^j \phi_i) - i (D - 1) (Q_k^i \phi_j) (Q^{ij} \phi_i) \]

\[ = i \rho^i \bar{\rho}^j - i \frac{D - 1}{D} \sigma^T \bar{\sigma} \]

\[ = -i \rho^i C \gamma^0 \bar{\rho}^j + i \frac{D - 1}{D} \sigma^T C \gamma^0 \bar{\sigma} \]

\[ = i \rho^i \bar{\rho} \bar{\rho}^j - i \frac{D - 1}{D} \sigma^T \bar{\sigma}, \]

(3.14)

where in the second to last line we used the reality conditions (3.12) and in the last line we restricted to a real representation, \( C = \gamma^0 \).

This motivates the definition of the brackets

\[ \{ \rho_i, \rho^j \} = -\frac{i}{2} \delta^i_j \quad \text{and} \quad \{ \sigma, \sigma \} = i \frac{D}{2(D - 1)} \],

(3.15)

together with the reality conditions \( \rho_i^* = \rho_i \), \( \sigma^* = \sigma \) (cf (3.12)) and additionally introduced constraints to account for the superfluous fermionic degrees of freedom,

\[ \Lambda_\alpha := \gamma^0_{\alpha\beta} \rho^\beta \approx 0. \]

(3.16)

We need to check that the extension is valid, i.e. that the Poisson brackets of the \( \phi_i \), considered as functions on the extended phase space, are equal to the Dirac brackets (3.6) of the system before we did the extension. Using \( \phi_i = P_{ij} \rho^j + \frac{1}{D} \gamma^i \) \( \sigma \) (cf (3.11)) and the Poisson brackets (3.15), this can be checked explicitly (this calculation shows why the factors of \( \frac{1}{2} \) in (3.15) are needed). Using this, we can express the constraints \( \mathcal{H} \) and \( \mathcal{S} \) in terms of the new variables in the obvious way and know that their algebra is unchanged. In particular, since the projectors are built from intertwiners, we find for the fermionic part of the Gauß constraint

\[ G^{ij} = \cdots + (i \rho^T \left[ 2 \eta^i_{\eta^j} + i \Sigma^{ij} \eta^i \right] ) \rho^j + \left( -i \frac{D - 1}{D} \right) \left[ i \Sigma^{ij} \right] \sigma, \]

(3.17)

which allows for an easy generalization to \( \text{SO}(D + 1) \) or \( \text{SO}(1, D) \) as a gauge group. Furthermore, since \( \rho^j \) in the other constraints only appear in the combination \( P_{ij} \rho^j \), they automatically Poisson-commute with \( \Lambda_\alpha \).

\(^5\) When considering the free Rarita–Schwinger action, this decomposition also appears to isolate the physical degrees of freedom, cf e.g. [26]. The ‘trace part’ \( \sigma \) is unphysical for the free field.
Note that if we now would calculate the Dirac bracket, we would obtain \(\{\rho_i, \rho_j\}_D = -\frac{i}{2} [\tilde{\rho}]_{ij}\), which again is non-trivial. Instead, we directly enlarge the phase space from \(\{\rho', \sigma\}\) to \(\{\rho', \sigma\}\), with, as a first guess, the brackets \(\{\rho_i, \rho_j\} = -\frac{i}{2} \eta_{ij}\), \([\sigma, \sigma] = \frac{D}{2D-1}\), the reality conditions \(\rho_i^* = \rho_i, \sigma^* = \sigma\) and the constraints
\[
N^i \rho_i \approx 0 \quad \text{and} \quad \gamma^i \rho_i \approx 0. \quad (3.18)
\]
Unfortunately, this immediately leads to an inconsistency in the case of the compact gauge group \(SO(D+1)\), since for our choice of Dirac matrices, \(\gamma^i\) necessarily is complex in the Euclidean case. Therefore, the reality conditions again are not \(SO(D+1)\) covariant and constraints (3.18) only are consistent in the time gauge \(N^i = \delta^i_0\). With a more elaborate choice of reality condition, it is possible to define a consistent theory, which will be the subject of the following section.

3.2. \(SO(D+1)\) gauge supergravity theory

As we just have seen, the remaining obstacle on our road to extending the internal gauge group from \(SO(D)\) to \(SO(D+1)\) is that the real vector space \(V\) of real \(SO(1,D)\) Majorana spinors is not preserved under \(SO(D+1)\) whose spinor representations are necessarily on complex vector spaces. Let \(V_C\) be the complexification of \(V\). Now \(SO(D+1)\) acts on \(V_C\) but the theory we started from is not \(V_C\) but rather the \(SO(D+1)\) orbit of \(V\). This is the real vector subspace
\[
V_R = \{ \theta \in V_C; \exists \rho \in V, g \in SO(D+1) \ni \theta = g \cdot \rho \}, \quad (3.19)
\]
where \(g\) denotes the respective representation of \(SO(D+1)\). This defines a reality structure on \(V_C\), that is, \(V_C = V_R \oplus iV_R\). The mathematical problem left is therefore to add the reality condition that we are dealing with \(V_R\) rather than \(V_C\).

In order to implement this, recall that any \(g \in SO(D+1)\) can be written as \(g = BR\) where \(B\) is a ‘Euclidean boost’ in the \(0j\) planes and \(R\) a rotation that preserves the internal vector \(n^0_0 := \delta_0^0\). The spinor representation of \(R\) just needs \(\gamma_j\) which is real valued. It follows that (3.19) can be replaced by
\[
V_R = \{ \theta \in V_C; \exists \rho \in V, B \in SO(D+1) \ni \theta = B \cdot \rho \}. \quad (3.20)
\]
The problem boils down to extracting from a given \(\theta \in V_R\) the boost \(B\) and the element \(\rho \in V\), that is, we need a kind of polar decomposition. If \(V_C\) would be just a vector subspace of some \(\mathbb{C}^n\), we could do this by standard methods. But this involves squaring of and dividing by complex numbers and these operations are ill defined for our \(V_C\) since Grassmann numbers are nilpotent. Thus, we need to achieve this by different methods.

The natural solution lies in the observation that if we use the linear simplicity constraint, then the \(D\) boost parameters can be extracted from the \(D\) rotation angles in the normal \(N^i = B_{ij} n^0_j\) to which we have access because \(N\) is part of the extended phase space. To be explicit, let \(\epsilon^{(A)}\) be the standard base of \(\mathbb{R}^{D+1}\), that is, \(\epsilon_{j}^{(A)} = \delta_j^A\). We construct another orthonormal basis \(\hat{b}_j^{(A)}\) of \(\mathbb{R}^{D+1}\) as follows.

Let \(b_0^{(0)} := N\) and
\[
b_j^{(0)} = \sin(\phi_1) \ldots \sin(\phi_{D-1}) \sin(\phi_D), \quad b_j^{(0)} = \sin(\phi_1) \ldots \sin(\phi_{D-j}) \cos(\phi_{D+1-j}); \quad j = 1 \ldots D,
\]
with \(\phi_1, \ldots, \phi_{D-1} \in [0, \pi]\) and \(\phi_D \in [0, 2\pi]\) modulo usual identifications and singularities of polar coordinates. Define
\[
b_j^{(i)} = \frac{\partial b_j^{(0)}}{\partial \phi_j} / \|\partial b^{(0)} / \partial \phi_j\|, \quad (3.22)
\]
\(\gamma^i \rho_i \approx 0\) is a complex constraint and thus equal to two real constraints. Only in time gauge, its imaginary part is already solved by demanding \(N^i \rho_i \approx 0\).
where the denominator denotes the Euclidean norm of the numerator. Then it may be checked by straightforward computation that
\[ \delta^{IJ} b_j^{(A)} b_j^{(B)} = \delta^{AB}. \] (3.23)

We consider now the SO\((D + 1)\) matrix
\[ (A(N)^{-1})_{IJ} := \sum_{A=0}^{D} b_j^{(A)} e_j^{(A)}, \] (3.24)
which has the property that \(A(N)^{-1} \cdot e^{(0)} = N\).

Now starting from the time gauge, \(g \in SO(D + 1)\) acts on \(V\) and produces \(N = g \cdot e^{(0)}\) and \(\theta = g \cdot \rho\). We decompose \(g = A(N)^{-1}R(N)\) where \(A(N)^{-1}\) is the boost defined above and \(R \cdot e^{(0)} = e^{(0)}\) is a rotation preserving \(e^{(0)}\). It follows that we may parametrize any pair \((N, \theta)\) with \(||N|| = 1\) and \(\theta \in V_\mathbb{R}\) as \(A(N)^{-1} \cdot (e^{(0)}, \rho)\) where \(\rho \in V\). We need to investigate how \(SO(D + 1)\) acts on this parametrization. On the one hand, we have
\[ [g A(N)^{-1}]_{IJ} = \sum_A (gb_j^{(A)})_I e_j^{(A)}. \] (3.25)

On the other hand, we can construct \(A(g \cdot N)^{-1}\) by following the above procedure, that is, computing the polar coordinates \(\theta_{ij}\) of \(g \cdot N\) and defining the \(b_j^{(A)}(g \cdot N)\) via the derivatives with respect to the \(\theta_{ij}\). The common element of both bases is \(g \cdot N = g \cdot b^{(0)}\). Therefore, there exists an element \(R(g, N) \in SO(D)\) such that
\[ g \cdot b^A(N) = R_{\delta j}(g, N)b_j^{(A)}(g \cdot N), \] (3.26)
or with \(R_{00} = 1, R_{0i} = R_{i0} = 0\),
\[ g \cdot b^A(N) = R_{\delta j}(g, N)b_j^{(A)}(g \cdot N) \] (3.27)
defines a rotation in \(SO(D + 1)\) preserving \(e^{(0)}\). Putting these findings together, we obtain
\[ [g \cdot A(N)^{-1}]_{IJ} = \sum_{A,B} R_{\delta A}(g, N) b_j^{(B)}(g \cdot N) e_j^{(A)} = \sum_A R_{\delta j}(g, N) b_j^{(A)}(g \cdot N) \]
\[ = \sum_{A} R_{\delta j}(g, N) b_j^{(A)}(g \cdot N) \delta_k^{(A)} = [A(g \cdot N)^{-1}R(g, N)]_{IJ}. \] (3.28)

Hence, the matrix \(A(N)^{-1}\) plays the role of a filter in the sense that the action of \(SO(D + 1)\) on \(A(N)^{-1} \cdot \rho\) can be absorbed into the matrix \(A^{-1}\) parametrized by \(g \cdot N\) modulo a rotation that preserves \(V\) and thus altogether the decomposition of \(V_\mathbb{R} = [A(N)^{-1} \cdot V; ||N|| = 1]\) is preserved with the expected covariant action of \(SO(D + 1)\) on \(N\). It therefore makes sense to impose the reality condition that \(A(N)\theta\) is a real spinor. In the subsequent construction, this idea will be implemented together with an extension of the phase space \(\rho_j \rightarrow \rho_k\) subject to the constraint \(N^l \rho_l = 0\). All these constraints and the reality conditions are second class and we will show explicitly that the symplectic structure reduces to the time gauge theory. Despite the fact that we end up with a non-trivial Dirac (anti) bracket, it can nevertheless be quantized and non-trivial Hilbert space representations can be found as we will demonstrate in the next section.

We define \(A(N) \in SO(D + 1)\) quite generally\(^7\) in the spin-1 representation by the equation
\[ A_{IA}^J N^J = \delta^I_0. \] (3.29)

\(^7\) There exist other possible choices apart from the construction using polar coordinates which might be better suited for certain problems. In \(D = 3\), we can, e.g., construct \(A(N)\) as a linear function of the components of \(N^l\) by using \(A_{0i} = N_i\) and subsequently interchanging the components of \(N^l\) with appropriate signs for the remaining columns of \(A(N)\).
It is determined up to SO($D$) rotations. From the above equation, it follows that

$$A_{0l} = N_l$$ and $$A_{ lj} \bar{X}^l = \delta^l_j A_{ lj} \bar{X}^l$$

(3.30)

for $$\bar{X}^l$$ arbitrary. The corresponding rotation on spinors will be denoted by $$A$$. This matrix rotates the normal $$N^l$$ into its time gauge value $$\delta^l_j$$ without imposing time gauge explicitly, which we will use to circumvent the reality problems of the SO($D + 1$) theory mentioned above appearing if we do not choose time gauge. We introduce the set of variables $$(A_{aIJ}, \pi^{bKL}, N^l, P_l, \rho, \theta, \sigma, \sigma^*)$$ together with the following non-vanishing Poisson brackets:

$$\{A_{aIJ}(x), \pi^{bKL}(y)\} = 2\eta_{a}^{[b} \eta_{J}^{c]} \delta^{D}(x-y), \quad \{N^l(x), P_j(y)\} = \delta^l_j \delta^{D}(x-y),$$

(3.31)

$$\{\rho_l(x), \rho^*_j(y)\} = -i\eta_{lj} \delta^{D}(x-y),$$

$$\{\sigma(x), \sigma^*(y)\} = i\frac{D}{D-1} \delta^D(x-y),$$

and the reality conditions

$$\chi_l := A_{l0} - (A_{0l})^* = 0, \quad \chi := A\sigma - (A^* \sigma)^* = 0,$$

(3.32)

which just say that the fermionic variables are real as soon as the normal $$N^l$$ gets rotated into time gauge. Note that before imposing the constraints, $$\rho, \theta$$ are complex Graßmann variables and only the Poisson brackets between these and their complex conjugates are non-vanishing. The non-vanishing brackets between themselves of the previous section will be recovered when replacing the above Poisson bracket by the corresponding Dirac bracket.

Additionally, we want that the variables transform nicely under spatial diffeomorphisms and gauge transformations; thus, we add

$$G^{ij} := D_a \pi^{aIJ} + 2\pi^{[ij} N^{j]} + 2i\rho^{[ij} \rho^{j]} + i\rho^i_k [i\Sigma^{lj}] \rho^j_k - i \left( \frac{D-1}{D} \sigma^* \right) [i\Sigma^{lj}] \sigma + \cdots$$

(3.33)

The old variables are expressed in terms of the new ones by

$$E^{ai} := \xi \Lambda^{ij} \tilde{\eta}_{iK} \pi^{aKL} N_i, \quad K_{ai} = \xi A^i_{aKL} (A_{aKL} - \Gamma_{aKL}(\pi)) N^l,$$

$$\rho_i = \frac{1}{2} A_{ij} \tilde{\eta}^{ij} (A \rho^i_K + A^* \rho^i_K), \quad \sigma = \frac{1}{2} (A\sigma + A^* \sigma^*),$$

(3.35)

where the bar here means rotational components w.r.t. $$N^l, \tilde{\eta}^{ij} := \eta_{ij} - \eta N_i N_j$$. To remove unnecessary degrees of freedom, we need the constraints

$$S^a_{ijkl} := \epsilon_{ijklm} N^j \pi^{aKL}, \quad N^l := N^l N_i - \zeta,$$

$$\Lambda := \gamma^l A_{ij} \tilde{\eta}^{ik} (A \rho^j K + A^* \rho^j K) = A_{ij} \tilde{\eta}^{ik} (\rho^j K + A^{-1} A^* \rho^j K),$$

$$\Theta := N^l (A \rho^i K + A^* \rho^i K),$$

(3.36)

together with the Hamilton and supersymmetry constraints, where we replace the old by the new variables as shown above. To prove that this theory is equivalent to supergravity and can possibly be quantized, we have to answer the following questions.

- Are the reality conditions (3.32) consistent? That is, do they transform under gauge transformations in a sensible way and do they (weakly) Poisson-commute with the other constraints?
Are the Poisson brackets of the old variables when expressed in terms of the new ones (3.35) equal to those on the old phase space? Does the constraint algebra close, i.e. do the newly introduced constraints (3.36) fit ‘nicely’ in the set of the old constraints? If not, do at least the constraints which were of the first class before the enlargement of the gauge group retain this property?

Do the constraints, especially the Gauß and spatial diffeomorphism constraints, reduce correctly?

Which Dirac brackets arise from the reality conditions? In view of a later quantization, we can find variables such that the Dirac brackets become simple?

Concerning all other constraints, note that they, by construction, depend only on newly introduced constraints (3.36). Is there a way of putting them in a ‘nice’ way under SO(1 + 3) gauge transformations (we will discuss \( \rho \) in the following; \( \sigma \) can be treated analogously). For \( g \in SO(D + 1) \), the reality condition transforms as follows:

\[
A(N)\rho^I = A(N)^* \rho^{I*} \rightarrow g^{JK} A(g \cdot N) g \rho_K = g^{JK} A(g \cdot N)^* g^{* \rho_K^*}. \tag{3.37}
\]

Since \( g^{IJ} \) is real, it is sufficient to consider the transformation behaviour of the spinor \( A \rho I \), so we will skip the action on internal indices in the following. Note that every rotation can be split up in a part which leaves \( N^I \) invariant and a ‘Euclidean boost’ changing \( N^0 \). For the rotations, \( A \) is invariant and we find using \( A \tilde{g} \tilde{g}^{-1} = \tilde{g}^{-1} A \tilde{g}^0 K \) and \( \Sigma^{ij} = -\Sigma^{ji} \)

\[
\delta \hat{\lambda}_I \rho_I = i \hat{\lambda}_{JK} A \Sigma^{JK} \rho_I = i \hat{\lambda}_{JK} A \Sigma^{JK} A^{-1} \rho_I = i \hat{\lambda}_{JK} A^{-1} \rho_I = i \hat{\lambda}_{JK} \Sigma^{LM} A \rho_I = i A_{[L} A_{M[K]} \hat{\lambda}_{JK} \Sigma^{LM} A \rho_I = i A_{[L} A_{M[K]} \hat{\lambda}_{JK} \Sigma^{LM} A \rho_I = i A_{[L} A_{M[K]} \hat{\lambda}_{JK} \Sigma^{LM} A \rho_I = i A_{[L} A_{M[K]} \hat{\lambda}_{JK} \Sigma^{LM} A \rho_I.
\]

For finite transformations \( \tilde{g} \in SO(D)_N \) stabilizing \( N^I \), we thus have \( A \rho_I \rightarrow \tilde{A} \tilde{g} \rho_I = g_0 A \rho_I \), where \( g_0 \in SO(D)_{b_0} \) stabilizes the zeroth component and thus is, with our choice of representation, a real matrix. Hence, reality conditions transform again into reality conditions under rotations. For a boost \( b \), the situation is a bit more complicated. Under a boost, \( A \) will transform intricately, but we know that (a) the matrix remains orthogonal by construction, and (b) that \( A_{0K} = N_K \rightarrow A_{K} N_L = -A_{K}A_{L} \). The most general transformation compatible with the above is \( A_{IJ} \rightarrow (g_0)_{IK} A_{KL} (\tilde{g}^{-1})_{LN} (b^{-1})_{NJ} (\tilde{g}^{-1})_{MJ} \)

where \( g_0 \in SO(D)_{0} \) is some group element which does not change the zeroth component, \( \tilde{g} \in SO(D)_N \) is in the stabilizer of \( N^I \) and \( b \tilde{g} \in SO(D)_{bN} \). Since we have \( SO(D)_N = b^{-1} SO(D)_{bN} b \), we can eliminate \( b \tilde{g} \) by a redefinition of \( b \). By definition of a representation, we then also have \( A \rightarrow g_0 A \tilde{g}^{-1} b^{-1} \) and thus

\[
A \rho_I \rightarrow g_0 A \tilde{g}^{-1} b^{-1} \rho_I = g_0 A \tilde{g}^{-1} \rho_I = \tilde{g}_0 A \rho_I. \tag{3.40}
\]

where in the last step we used the result we obtained for rotations above. Since \( \tilde{g}_0 \in SO(D)_0 \) is real, we see that under a ‘Euclidean boost’ the reality condition can only get rotated. What remains to be checked is that the reality condition Poisson-commutes with all other constraints. It transforms covariantly under spatial diffeomorphisms by inspection and, as we have just proven, it forms a closed algebra with \( SO(D + 1) \) gauge transformations. Concerning all other constraints, note that they, by construction, depend only on \( \Im(A \rho_I) \)
Lagrange multiplier

Strictly speaking, this is true only for

Because of orthogonality, we trivially have

to the projector

This automatically implies that the algebra of \( \mathcal{H} \) and \( S \) remains unchanged if we replace the old variables by (3.35). From (3.35), it is also clear that \( \mathcal{H} \) and \( S \) Poisson-commute with \( S_{\overline{M}}^{\mu} \) and \( \mathcal{N} \). By inspection, all constraints transform covariant under spatial diffeomorphisms. More surprisingly, all constraints Poisson-commute with \( G^{ij} \). This can be seen quite easily for \( G^{ij}, \mathcal{H}, S_{\overline{M}}^{\mu}, \mathcal{N} \) and also for \( \Lambda \) and \( \Theta \) (note that \( A \) and \( \Lambda_{ij} \) are invertible and that \( (\rho_{ij} + A^{-1}A^{*}\rho_{ij}^{*}) \) transforms like \( \rho_{ij} \) which can be shown using the methods above). For \( \mathcal{H} \) and \( S \), this is, at first sight, a small miracle, since the replacement rules (3.35) of all old variables depend on \( A(N) \), which is known to transform oddly. But the matrices \( A \) are placed such that they, in fact, either (a) appear in the combinations \( (\rho_{ij} + A^{-1}A^{*}\rho_{ij}^{*}) \) and \( (\rho_{ij} + \rho_{ij}^{*}A^{T}A) \), which can easily be shown to transform like \( \rho^{ij} \) and \( \rho_{ij}^{*} \), respectively, with the methods above, or (b) all cancel out! The general situation is as follows: \( \rho_{ij} \) is replaced by \( \rho_{ij} = A^{T}\tilde{\eta}_{ij}(\rho_{ij} + A^{-1}A^{*}\rho_{ij}^{*}) \) and \( \rho_{ij}^{*} \) by \( \rho_{ij}^{*} = A^{T}\tilde{\eta}_{ij}(\rho_{ij} + \rho_{ij}^{*}A^{T}A)A^{-1} \), where the expression in the brackets transform sensibly (cf above). The free internal indices of \( E^{\mu} \), \( \Lambda_{ij} \) and \( \rho_{ij} \) are either contracted with each other, and then in the replacement the \( \Lambda_{ij} \)s will cancel because of orthogonality, or with \( \gamma^{i} \), which will be contracted from both sides with \( A(N) \) and all \( A \) cancel due to \( (A^{-1})_{ij}A^{-1}\gamma^{i}A = \gamma_{j} \). Cancelling the \( A \) makes \( \mathcal{H} \) gauge invariant and \( S \) gauge covariant by inspection, if we replace all \( \gamma^{0} \) by \( i\gamma^{1} \). Thus, we are left with \( \Theta \) and \( \Lambda \), which are their own second-class partners but Poisson-commute with everything else, which can be seen as follows. For \( \Theta \), note that \( \mathcal{H} \), \( S \) and \( \Lambda \) only depend on \( \tilde{\eta}^{\mu}(A_{\mu}^{i} + A^{*}\rho_{\mu}^{i}) \), which Poisson-commutes with \( \Theta \) due to the projector \( \tilde{\eta} \). For \( \Lambda \), the situation again is more complicated. Remember that \( \mathcal{H} \) and \( S \) in the time gauge only depended on \( X^{\mu}A_{\mu}^{i} \) for some \( X^{i} \). Whatever \( X^{i} \) may be, under (3.35) it will be replaced by something of the form \( \tilde{X}^{k}X_{i}^{j} \) and the whole expression will become \( \tilde{X}^{k}X_{i}^{j}P_{ijk}^{\mu}A_{\mu}^{i}(A_{\mu}^{i} + A^{*}\rho_{\mu}^{i}) \) with \( \tilde{P}_{ij} = \delta_{ij} - \frac{1}{2}\gamma_{i}\gamma_{j} \). Crucial for the

Because of orthogonality, we trivially have \( A_{ij}A_{jk} = \eta_{ik} \). Additionally, \( A_{ij}\tilde{\eta}_{ij} = A_{ij} \), which can be seen from \( A_{jk}N^{k} = 0 \). Therefore, \( A_{ij}\tilde{\eta}_{ij} = A_{ij} \tilde{\eta}_{ij} = \eta_{ij} \).

Strictly speaking, this is true only for \( \mathcal{H} \) since it has no free indices. For \( S \) we may change the definition of the Lagrange multiplier \( \psi_{i} \rightarrow \psi_{j}A \) to make it hold.
Note that the Dirac matrix is block diagonal. Therefore, we do not need to consider the full Dirac matrix at once.

For the Dirac matrix, we find

- By construction,
- Thus, the Dirac brackets of the \( \rho \) that the generic term is Poisson-commuting with \( \Lambda \),

\[
\{ \bar{\chi}^j A^{ijkl} \bar{\eta}^l M (A\rho_M + A^* \rho_M^*), \gamma^N A_{NO\eta^{OP}} (A\rho_P + A^* \rho_P^*) \} = -i \bar{\chi}^j A^{ijkl} \bar{\eta}^l M (\gamma^N)^T N_{MN} = -i \bar{\chi}^j A^{ijkl} \gamma^r A_{rl} = -i \bar{\chi}^j A^{ijkl} \gamma^k = 0.
\] (3.44)

The constraint algebra is summarized in table 1.

### Table 1. List of first- and second-class constraints.

| First-class constraints | Second-class constraints |
|-------------------------|-------------------------|
| \( G^{IJ}, \tilde{\eta}_{\mu\nu}, \mathcal{H}, S, S^\mu_{\gamma\mu} \) and \( \mathcal{N} \) | \( \Lambda, \Theta, \chi_l \) and \( \chi \) |

The following calculation is property (3.30), which will be used several times. Then we find that the generic term is Poisson-commuting with \( \Lambda \),

\[
\{ \bar{\chi}^j A^{ijkl} \bar{\eta}^l M (A\rho_M + A^* \rho_M^*), \gamma^N A_{NO\eta^{OP}} (A\rho_P + A^* \rho_P^*) \} = -i \bar{\chi}^j A^{ijkl} \bar{\eta}^l M (\gamma^N)^T N_{MN} = -i \bar{\chi}^j A^{ijkl} \gamma^r A_{rl} = -i \bar{\chi}^j A^{ijkl} \gamma^k = 0.
\] (3.44)

The constraint algebra is summarized in table 1.

- By construction, \( \mathcal{H} \) and \( S \) reduce correctly if we choose the time gauge \( N^I = \delta^I_0 \), which automatically implies \( A_{IJ} \rightarrow (g_0)_{IJ} \in SO(D)_0 \). Since the theory is \( SO(D)_0 \) invariant, a gauge transformation \( g_0 \rightarrow 1 \) can be performed, which implies \( \rho^I = \rho^I_0 \). From this, one easily deduces that \( G^{IJ} \) and \( \tilde{\eta}_{\mu\nu} \) also reduce correctly. Since the theory was \( SO(D + 1) \) invariant in the beginning, these results do not depend on the gauge choice.

- For the Dirac matrix, we find

\[
C_{IJ} = \left[ A\rho_I - (A\rho_I)^*, A\rho_J - (A\rho_J)^* \right] = -i \eta_{IJ} \left[ -AA^* - A^*A^T \right] = 2i \eta_{IJ}
\] (3.45)

\[
(C^{-1})^J = -\frac{1}{i} \eta^J
\] (3.46)

\[
\{ \rho_I, \rho_J \}_{DB} = -\{ \rho_I, A\rho_K - (A\rho_K)^* \} (C^{-1})^{KL} \{ A\rho_L - (A\rho_L)^*, \rho_J \}
\]

\[
= -\frac{i}{2} \eta_{IJ} A^* A^T.
\] (3.47)

and for \( \sigma \) analogously. We now can choose new variables which have simpler brackets. Motivated from the original replacement (3.35), we define

\[
\rho^I_0 := A^{IJ} \rho_J, \quad \sigma_r := A\sigma_r
\] (3.48)

\[
(\rho^I_0)^* = A^{IJ} A^* (A^*)^{-1} A\rho_I = \rho^I_0, \quad (\sigma_r)^* = \sigma_r
\] (3.49)

with the Dirac brackets

\[
\{ \rho^I_0, \rho^J_0 \}_{DB} = \{ A^{IK} A\rho_K, A^{IJ} A\rho_L \}_{DB} = -\frac{i}{2} \eta^{IJ} AA^T A^T = -\frac{i}{2} \eta^{IJ} 1
\] (3.50)

\[
\{ \sigma_r, \sigma_r \} = i \frac{D}{2(D - 1)} 1.
\] (3.51)

Thus, the Dirac brackets of the \( \rho^I_0, \sigma_r \) are simple as are the reality conditions. Only the transformation behaviour of the new variables under \( SO(D + 1) \) rotations is complicated because of the appearance of the rotation \( A \) in their definition. Note that also \( \{ P^I, P^J \}_{DB}, \{ P^I, \rho^J_0 \}_{DB} \) and \( \{ P^I, \sigma_r \}_{DB} \) will be non-zero. Therefore, we also choose a new variable \( P^I \) with simple Dirac brackets, which can most easily be found by performing the symplectic

\[10\] Note that the Dirac matrix is block diagonal. Therefore, we do not need to consider the full Dirac matrix at once.
reduction. After that, we can simply read it off the symplectic potential. We find using
\( \rho_i = A_{ij}A^{-1}\rho^j \) and \( \rho^j_i = A_{j}^{(i)}A \)
+ \(i\rho_i^j - i\frac{D-1}{D}\sigma^j\delta + P^i\mathcal{N}_i\)
\[= iA_{ij}^{(i)}A(A_{kl}A^{-1}\rho^k) - \frac{D-1}{D}\sigma^jA(A^{-1}\sigma_r) + P^i\mathcal{N}_i\]
\[= (\rho^j)A_{ij}^{(i)}A(A_{kl}A^{-1}\rho^k) + \frac{D-1}{D}\sigma^jA(A^{-1}\sigma_r) - \frac{D-1}{D}\sigma^jA\rho^j\]
\[+ i\left(A_{kl}^{(j)}A_{ij}^{(i)}\frac{\partial A_{kl}}{\partial N_j}\rho^k + (\rho^j)A_{ij}^{(i)}A_{kl}^{(j)}A^{(i)}A^{-1}\sigma_r\right)\mathcal{N}_i\]
\[= i(\rho^j)A_{ij}^{(i)}A + \frac{D-1}{D}\sigma^jA\rho^j + P^i\mathcal{N}_i,\] (3.52)
with \( \mathcal{P}^j := P^j + iA_{ij}^{(i)}A_{kl}^{(j)}A^{(i)}A^{-1}\rho^k + \frac{D-1}{D}\sigma^jA\rho^j - \frac{D-1}{D}\sigma^jA\rho^j\). It can be checked explicitly that \( \mathcal{P}^j \), expressed in the old variables \( (P^i, N_j, \rho_i, \rho^j, \sigma, \sigma) \), Poisson-commutes with the reality conditions and with itself, and therefore has nice Dirac brackets. For the spatial diffeomorphism constraint, a short calculation yields
\[\mathcal{H}_a = P^j\delta_a\mathcal{N}_j - \frac{i}{2}\partial_\sigma(\rho^j)\rho^j + \frac{i}{2}\rho^j_\sigma\rho^j + \frac{D-1}{2D}\partial_\sigma(\sigma^j)\sigma - \frac{D-1}{2D}\sigma^j\delta_a\sigma + \ldots\]
\[= \mathcal{P}^j\delta_a\mathcal{N}_j + i(\rho^j)\delta_a\rho^j - \frac{D-1}{D}\sigma^j\delta_a\sigma + \ldots,\] (3.53)
which by inspection generates spatial diffeomorphisms on the new variables. The constraints \( \Lambda \) and \( \Theta \) become
\[\Lambda = \gamma_\rho \rho^j \approx 0 \quad \text{and} \quad \Theta = \rho^j_\rho \approx 0,\] (3.54)
which look utterly non-covariant, but which by construction still Poisson-commute with the \( \text{SO}(D+1) \) Gauss constraint. It therefore has to have a complicated form. We find
\[G^{ij} = 2P^{[i}N^{j]} + 2\rho^{[ij]}\rho^{j]} + i\rho_i^{[i}\rho_j^{j]} - i\left(\frac{D-1}{D}\sigma^i\right)[i|\Sigma^{ij}]\sigma + \ldots\]
\[= 2P^{[i}N^{j]} + 2\rho^{[ij]}A_{kl}^{[i}A_{kl}^{j]}\rho^k + i\rho_i^{[i}\rho_j^{j]}A[|\Sigma^{ij}]A^{-1}\rho^k + \frac{D-1}{D}\sigma^jA[|\Sigma^{ij}]A^{-1}\rho_i + 2i\left(A_{kl}^{[i}\rho_j^{j]}\frac{\partial A_{kl}}{\partial N_j}\rho^k\right)\]
\[+ (\rho^j)A_{ij}^{(i)}A^{-1}\partial_\sigma^jA_{kl}^{(j)}A^{(i)}A^{-1}\rho_k - \frac{D-1}{D}\sigma^jA\rho^j\] (3.55)

Finally, we solve the remaining second-class constraints \( \Lambda \) and \( \Theta \) which after a short calculation result in the final Dirac brackets
\[\{\rho^j, \rho^j\}_{DB} = -\frac{i}{2}\delta^{ij}, \quad \{\rho^j_\rho, \rho^j_\rho\}_{DB} = 0, \quad \{\rho^j, \rho^j_\rho\}_{DB} = 0.\]
As a consistency check, we can consider
\[\{\phi^j, \phi^j\}_{DB} = \left\{\rho^j_\rho + \frac{1}{D}\gamma^j\sigma_r, \rho^j + \frac{1}{D}\gamma^j\sigma_r\right\}_{DB} = -(C^{-1})^{ij},\] (3.56)
which coincides with the Dirac brackets obtained in (3.6).

The form of the Hamiltonian and supersymmetry constraints \( \mathcal{H}, \mathcal{S} \) strongly depends on the supergravity theory under consideration. Exemplarily, we cite the supersymmetry constraint
in $D = 3, N = 1$ supergravity from [38] adapted to our notation,

$$ S = -\frac{i}{2} \epsilon^{abc} \gamma_{5} \left[ \gamma_{a} e_{a}^{\mu} \hat{D}_{b} \left( \frac{1}{\sqrt{q}} \gamma^{\mu} \phi_{r} \right) + \hat{D}_{b} \left( \frac{1}{\sqrt{q}} \gamma_{a} e_{a}^{\mu} \phi_{r} \right) \right] $$

$$ + \frac{1}{2 \sqrt{q}} \epsilon^{abc} \epsilon_{ijk} e_{a}^{\mu} \left( K_{b}^{c} + \hat{\wp}_{b} \gamma^{0} \gamma^{ij} E_{b}^{\mu} \phi_{n} \right) \gamma^{k} e_{c}^{\mu} \phi_{n}, \quad (3.57) $$

where $\hat{D}_{b} \phi_{r} = \partial_{b} \phi_{r} + \hat{\wp}_{b} \phi_{r} + \frac{i}{2} \hat{\wp}_{d} \Sigma^{d} \phi_{r}, \hat{\wp}_{b} = \Gamma_{aij} + \frac{i}{\sqrt{q}} \sqrt{q_{b}} \hat{\wp}_{a} (\phi_{i} \gamma_{d} \phi_{j} + \frac{2}{\sqrt{q}} \hat{\wp}_{b} \gamma_{d} \phi_{b})$ and $\Gamma_{aij}$ is the spin connection annihilating the triad. An explicit expression for $S$ in terms of the extended variables $(A, \pi, N, P, \rho, \rho^{*}, \sigma, \sigma^{*})$ can be found using (3.11) and (3.35). The corresponding constraint operator is obtained using the methods in section 4, appendix A.6 and [65, 54].

4. Background-independent Hilbert space representations for Majorana fermions

Background-independent Hilbert space representations for Dirac spinor fields were constructed in [28]. One may think that for the Rarita–Schwinger field or more generally for Majorana fermion fields, one can reduce this construction as follows. Consider the following variables:

$$ \xi^{IA} = \frac{1}{\sqrt{2}} (\rho^{2} + i \rho^{2+1}), \quad \pi^{IA} = \frac{-i}{\sqrt{2}} (\rho^{2} - i \rho^{2+1}), \quad \alpha = 1, \ldots, 2^{(D+1)/2}, \quad (4.1) $$

which have the non-vanishing Dirac brackets

$$ [\xi^{IA}(x), \pi^{JB}(y)] = -i \eta^{IJ} \delta^{\alpha} \delta^{(D)}(x - y) \quad (4.2) $$

and the simple reality condition

$$ \bar{\pi} = -i \xi. \quad (4.3) $$

The elements of the Hilbert space are field-theoretic extensions of holomorphic (i.e. they only depend on $\theta^{a}$) functions on the Graßmann space spanned by the Graßmann numbers $\theta^{a}$ and their adjoints $\bar{\theta}^{a}$, the operators corresponding to the phase space variables act as

$$ \hat{\xi} f := \theta f, \quad \hat{\pi} f := \frac{1}{i} \frac{d}{d \theta} f \quad (4.4) $$

and the scalar product

$$ \langle f, g \rangle := \int e^{\bar{\theta} a} \bar{f} g d \bar{\theta} d \theta \quad (4.5) $$

faithfully implements the reality conditions. There are, however, two drawbacks to this.

1. Due to the arbitrary split of the variables into two halves, the scalar product is not $SO(D)$ invariant which makes it difficult to solve the Gauß constraint.

2. The scalar product given above fails to implement the Dirac bracket resulting from the second-class constraints, that is, $[\rho^{a} \rho^{b}], \rho^{a} \rho^{b}]_{DB} = -i / 2 \mathbb{P}^{\alpha \beta}$. Recall that one must solve the second-class constraints before quantization; hence, it is not sufficient to consider the quantization of the Poisson bracket as was done above.

In what follows we develop a background-independent Hilbert space representation that is $SO(D)$ invariant, implements the Dirac bracket and is geared to real-valued (Majorana) spinor fields. We begin quite generally with $N$ real-valued Graßmann variables $\theta_{A}, A = 1, \ldots, N; \theta_{A} \theta_{B} = 0; \bar{\theta}^{*} = \theta$. We consider the finite-dimensional, complex vector space $V$ of polynomials in the $\theta_{A}$ with complex-valued coefficients. Note that $f \in V$ depends on all real Graßmann coordinates; it is not holomorphic as in the case of the Dirac spinor field [28]. Thus, dim$(V) = 2^{N}$ is the complex dimension of $V$. We may write a polynomial $f \in V$ in
several equivalent ways which are useful in different contexts. Let \( f_{A_1 \ldots A_n}^{(n)} \), \( 0 \leq n \leq N \), be a completely skew complex-valued tensor (\( n \)-form); then \( f \) can be written as

\[
f = \sum_{n=0}^{N} \frac{1}{n!} f_{A_1 \ldots A_n}^{(n)} \theta^{A_1} \cdots \theta^{A_n} = \sum_{n=0}^{N} \sum_{1 \leq A_1 < \cdots < A_n \leq N} f_{A_1 \ldots A_n}^{(n)} \theta^{A_1} \cdots \theta^{A_n}. \tag{4.6}
\]

An equivalent way of writing \( f \) is by considering for \( \sigma_k \in \{0, 1\} \) and \( A_1 < \cdots < A_n \) the relabelled coefficients

\[
f_{\sigma_1 \ldots \sigma_n} := f_{A_1 \ldots A_n}^{(n)}, \quad \sigma_k := \begin{cases} 1 & k \in \{A_1, \ldots, A_n\} \\ 0 & \text{else.} \end{cases}
\]

It follows

\[
f = \sum_{\sigma_1 \ldots \sigma_n \in \{0, 1\}} f_{\sigma_1 \ldots \sigma_n} \theta_1^{\sigma_1} \cdots \theta_N^{\sigma_n} \tag{4.8}
\]

with the convention \( \theta_0^0 := 1 \).

On \( V \) we define the obvious positive-definite sesqui-linear form

\[
\langle f, f' \rangle := \sum_{n=0}^{N} \sum_{\sigma_1 < \cdots < \sigma_n} f_{A_1 \ldots A_n}^{(n)} f_{A_1 \ldots A_n}^{(n)'} = \sum_{\sigma_1 < \cdots < \sigma_n} f_{\sigma_1 \ldots \sigma_n} f_{\sigma_1 \ldots \sigma_n}' \tag{4.9}
\]

as well as the operators

\[
[\theta_A \cdot f](\theta) := \theta_A f(\theta), \quad [\partial_A \cdot f](\theta) := f'(\theta)/\partial_A, \tag{4.10}
\]

where the latter denotes the left derivative on Graßmann space (see, e.g., [63] for precise definitions). Note the relations \( \partial_A \theta_B = \delta_{AB} \) which can be verified by applying them to arbitrary polynomials \( f \). We claim that operators (4.10) satisfy the adjointness relation

\[
\partial_A^\dagger = \delta_A, \tag{4.11}
\]

The easiest way to verify this is to use presentation (4.8). We find explicitly

\[
\theta_A \cdot f = \sum_{\sigma_1 < \cdots < \sigma_n} f_{\sigma_1 < \cdots < \sigma_n} (\sigma_1) \cdots (\sigma_n) \delta_{\alpha_1, 0} \theta_1^{\sigma_1} \cdots \theta_N^{\sigma_n} 
\]

\[
= \sum_{\sigma_1 < \cdots < \sigma_n} \left[ f_{\sigma_1 \cdots \sigma_n - 1} (\sigma_1) \cdots (\sigma_n) - \delta_{\sigma_1, 1} f_{\sigma_1 \cdots \sigma_n} (\sigma_1 - 1) \cdots (\sigma_n) \right] \theta_1^{\sigma_1} \cdots \theta_N^{\sigma_n} 
\]

\[
= \sum_{\sigma_1 < \cdots < \sigma_n} \tilde{f}_{\sigma_1 \cdots \sigma_n} (\sigma_1) \cdots (\sigma_n) \theta_1^{\sigma_1} \cdots \theta_N^{\sigma_n}, \tag{4.12}
\]

where the wide hat in the fourth line denotes omission of the variable. We conclude

\[
\langle f, \theta_A f' \rangle = \sum_{\sigma_1 < \cdots < \sigma_n} \tilde{f}_{\sigma_1 < \cdots < \sigma_n} \tilde{f}_{\sigma_1 < \cdots < \sigma_n}' 
\]

\[
= \sum_{\sigma_1 < \cdots < \sigma_n} \tilde{f}_{\sigma_1 \cdots \sigma_n - 1} (\sigma_1) \cdots (\sigma_n) \delta_{\sigma_1, 1} \tilde{f}_{\sigma_1 \cdots \sigma_n} (\sigma_1 - 1) \cdots (\sigma_n) 
\]

\[
= \sum_{\sigma_1 < \cdots < \sigma_n} \tilde{f}_{\sigma_1 \cdots \sigma_n} (\sigma_1) \cdots (\sigma_n) \delta_{\sigma_1, 0} \tilde{f}_{\sigma_1 \cdots \sigma_n} 
\]

\[
= \sum_{\sigma_1 < \cdots < \sigma_n} \tilde{f}_{\sigma_1 \cdots \sigma_n} \tilde{f}_{\sigma_1 \cdots \sigma_n} = \langle \partial_A f, f' \rangle. \tag{4.13}
\]
Although not strictly necessary, it is interesting to see whether the scalar product (4.9) can be expressed in terms of a Berezin integral, perhaps with a non-trivial measure as in [28] for complex Grassmann variables. The answer turns out to be negative: the most general Ansatz for a ‘measure’ is $d\mu = d\theta_1 \ldots d\theta_N$; $\mu(\theta)$ with $\mu \in V$ fails to reproduce (4.9) if we apply the usual rule for the Berezin integral $\int d\theta \ \theta^n = \delta_{n,1}$. Note that from this we induce $\int d\theta_A \ d\theta_B = -\int d\theta_B \ d\theta_A$ as one quickly verifies when applying to $V$. However, there exists a non-trivial differential kernel

$$K := (\theta_1 + (-1)^{N-1} \bar{\theta}_1) \ldots (\theta_N + (-1)^{N-1} \bar{\theta}_N)$$

such that

$$\langle f, f' \rangle = \int d\theta_N \ldots d\theta_1 \ f^* \ K \ f' ,$$

where we emphasize that $f^*$ is the Grassmann involution

$$f^* = \sum_{\sigma_1 \ldots \sigma_N} \bar{f}_{\sigma_1 \ldots \sigma_N} \theta_{\sigma_1}^0 \ldots \theta_N^{\sigma_N} = \sum_{\sigma_1 \ldots \sigma_N} \bar{f}_{\sigma_1 \ldots \sigma_N} (-1)^{N+\sum_{\sigma_k=0}^{\sigma_k=1} \sum_{\sigma_k=+} \sigma_k} \theta_1^{\sigma_1} \ldots \theta_N^{\sigma_N}$$

and not just complex conjugation of the coefficients of $f$. Note also that due to total antisymmetry, we may rewrite (4.15) in the form

$$\langle f, f' \rangle = \frac{(-1)^{N(N-1)/2}}{N!} \int d\theta_{A_1} \ldots d\theta_{A_N} \ f^* D_{A_1} \ldots D_{A_N} f'$$

where

$$D_{A} = \theta_A + (-1)^{N-1} \bar{\theta}_A .$$

Presentation (4.19) establishes that the linear functional is invariant under $U(N)$ acting on $V$ by

$$f \mapsto U \cdot f; \quad [U \cdot f]_{A_1 \ldots A_N} = f^{(n)}_{B_1 \ldots B_N} U_{B_1 A_1} \ldots U_{B_N A_N} ,$$

which is of course also clear from (4.9). Note that (4.19) formally corresponds to $\theta_A \mapsto U_{AB} \theta_B$ but this is not an action on real Grassmann variables unless $U$ is real valued. If we want to have an action on the linear polynomials with real coefficients, then we must restrict $U(N)$ to $O(N)$ or a subgroup thereof which will be precisely the case in our application. In this case, it is sufficient to restrict to real-valued coefficients in $f$ and now the real dimension of $V$ is $2^N$.

We sketch the proof that (4.14) accomplishes (4.15). We introduce the notation for $k = 1, \ldots, N$,

$$F_{\sigma_1 \ldots \sigma_N} := \sum_{\gamma_1 \ldots \gamma_N} f_{\sigma_1 \ldots \sigma_N} \theta_{\gamma_{k+1}}^{\gamma_k} \ldots \theta_N^{\sigma_N} ,$$

whence $F_{\sigma_1 \ldots \sigma_N} = \bar{f}_{\sigma_1 \ldots \sigma_N}$. Note that $F_{\sigma_1 \ldots \sigma_N}$ no longer depends on $\theta_1, \ldots, \theta_N$. Using this, we compute with $d^N \theta := d\theta_N \ldots d\theta_1$ and using anticommutativity at various places

$$\int d^N \theta \ f^* K \ f' = \int d^N \theta \ [F^* + F^+_1 \bar{\theta}] (\theta_1 + (-1)^{N-1} \bar{\theta}_1) D_2 \ldots D_N [F_0' + \bar{\theta}_1 F'_1]$$

$$= \int d^N \theta [F^*_0 (-1)^{N-1} D_2 \ldots D_N (\theta_1 + (-1)^{N-1} \bar{\theta}_1) [F'_0 + \bar{\theta}_1 F'_1]$$

$$+ F^*_1 (-1)^{N-1} D_2 \ldots D_N \theta_1 \bar{\theta}_1 [F'_0 + \bar{\theta}_1 F'_1]]$$

$$= \int d^N \theta [F^*_0 (-1)^{N-1} D_2 \ldots D_N [\bar{\theta}_1 F'_0 + (-1)^{N-1} F'_1]$$

$$+ F^*_1 (-1)^{N-1} D_2 \ldots D_N \theta_1 F'_1]$$

$$= \int d^N \theta [F^*_0 \bar{\theta}_1 D_2 \ldots D_N F'_0 + F^*_1 \bar{\theta}_1 D_2 \ldots D_N F'_1] ,$$

(4.21)

11 Rather a linear functional on $V$ which is of course also a non-Abelian Grassmann algebra.
where we used that the second term no longer is linear in $\theta_1$ and therefore drops out from the Berezin integral. The calculation explains why the factor $(-1)^{N-1}$ in (4.18) is necessary.

Next consider the first term in the last line of (4.21). We have

$$
\int d^N \theta F_{0_i}^* \theta_1 D_2 \ldots D_N F_0^* \theta_2 \cdot \theta_2 (\theta_2 + (-1)^{N-1} \partial_2) D_3 \ldots D_N [F_{0_0} + \theta_2 F_{0_1}]
$$

$$
= \int d^N \theta [F_{0_0}^* + F_{0_1}] \theta_1 \theta_2 (\theta_2 + (-1)^{N-1} \partial_2) D_3 \ldots D_N [F_{0_0}^* + \theta_2 F_{0_1}]
$$

$$
= \int d^N \theta [F_{0_0}^* (-1)^{N-2} \theta_1 D_3 \ldots D_N (\theta_2 + (-1)^{N-1} \partial_2) [F_{0_0}^* + \theta_2 F_{0_1}]
$$

$$
+ F_{0_1}^* (-1)^{N-2} \theta_1 D_3 \ldots D_N \theta_2 \partial_2 [F_{0_0}^* + \theta_2 F_{0_1}]
$$

$$
= \int d^N \theta [F_{0_0}^* (-1)^{N-2} \theta_1 D_3 \ldots D_N [\theta_2 F_{0_0} + (-1)^{N-1} F_{0_1}]
$$

$$
+ F_{0_1}^* (-1)^{N-2} \theta_1 D_3 \ldots D_N F_{0_1}^*]
$$

$$
= \int d^N \theta [F_{0_0}^* \theta_1 \theta_2 D_3 \ldots D_N F_{0_0}^* + F_{0_1}^* \theta_1 \theta_2 D_3 \ldots D_N F_{0_1}^*].
$$

(4.22)

Similarly for the second term in (4.21)

$$
\int d^N \theta F_{1_i}^* \theta_1 D_2 \ldots D_N F_1^* = \int d^N \theta [F_{1_0}^* \theta_1 \theta_2 D_3 \ldots D_N F_{1_0}^* + F_{1_1}^* \theta_1 \theta_2 D_3 \ldots D_N F_{1_1}^*].
$$

(4.23)

It is transparent how the computation continues: we continue expanding $F_{a_1 \ldots a_i} = F_{a_1 \ldots a_0} + \theta_{k+1} F_{a_1 \ldots a_k}$ and see by exactly the same computation as above that\footnote{A strict proof would proceed by induction which we leave as an easy exercise for the interested reader.} the signs match up to the effect that

$$
\int d^N \theta F_{a_1 \ldots a_i} \theta_1 \ldots \theta_k D_k \ldots D_N F_{a_1 \ldots a_k}
$$

$$
= \sum a_{i+1} \int d^N \theta F_{a_1 \ldots a_{i+1}} \theta_1 \ldots \theta_{k+1} D_{k+2} \ldots D_N F_{a_1 \ldots a_{k+1}},
$$

(4.24)

from which the claim follows using $\int d^N \theta \theta_1 \ldots \theta_N = 1$. In our applications, $N$ will be even so that $D_A = D_A - \theta_3$.

For our application to the Rarita–Schwinger field, we consider the compound index $A = (j, \alpha)$, $j = 1, \ldots, D$, $\alpha = 1, \ldots, 2^{(D+1)/2}$ or just $A = \alpha$ whence $N = DM$ or $N = M$ is even. We consider the auxiliary operator

$$
\bar{\rho}_j^\alpha := \sqrt{n} \left[ \rho_j^\alpha + i \bar{\rho}_j^\alpha \right],
$$

(4.25)

which by virtue of (4.11) is self-adjoint and satisfies the anticommutator relation

$$
[\bar{\rho}_j^\alpha, \bar{\rho}_k^\beta]_+ = \frac{\hbar}{2} \delta_{jk} \delta^{\alpha \beta}.
$$

(4.26)

However, $\bar{\rho}_j^\alpha$ is not yet a representation of $\rho_j^\alpha$ which satisfies the Dirac antibracket $[\rho_j^\alpha, \rho_k^\beta]_D = -\frac{\hbar}{2} \delta_{jk} \gamma^\beta$ and the reality condition $(\rho_j^\alpha)^* = \rho_j^{\alpha \dagger}$. Similarly, $[\sigma_a, \sigma_b]_D = i \frac{\sigma_a \sigma_b}{\sqrt{D-1}} \delta_{ab}$, $\sigma_a^* = \sigma_a$. Correspondingly, what we need is a representation $\pi(\rho_j^\alpha)$, $\pi(\sigma_a)$ of the abstract CAR-algebra defined by canonical quantization, that is,

$$
[\bar{\rho}_j^\alpha, \bar{\rho}_k^\beta]_+ = \frac{\hbar}{2} \delta_{jk} \gamma^\beta, \quad (\rho_j^\alpha)^* = \rho_j^{\alpha \dagger}, \quad [\sigma_a, \sigma_b]_+ = \frac{\hbar}{2(D-1)} \delta_{ab}, \quad (\sigma_a^*)^* = \sigma_a
$$

(4.27)
all other anticommutators vanishing. Fortunately, using that \( P^\alpha_{jk} \) is a real-valued projector (in particular, symmetric and positive semidefinite), we can now write the following faithful representation of our abstract \( \ast \)-algebra (4.27) on the Hilbert space \( \mathcal{H} = V_{DM} \otimes V_M \) defined above:

\[
\pi(\rho^\alpha_{ij}) := P^\alpha_{jk} \hat{\rho}^k_{ij}, \quad \pi(\sigma^\alpha_i) := \frac{1}{2\sqrt{D\hbar}} [\theta^\alpha_i + \partial^\alpha_i].
\]  

(4.28)

So far we have considered just one point on the spatial slice corresponding to a quantum mechanical system. The field theoretical generalization now proceeds exactly as in [28] and consists in considering the copies \( \mathcal{H}_x \) of the Hilbert space just constructed, one for every spatial point \( x \) and taking as representation space either the inductive limit of the finite tensor products \( \mathcal{H}_x \otimes \cdots \otimes \mathcal{H}_x \) of which the former is just a tiny subspace. The \( \ast \)-algebra (4.27) is then simply extended by adding labels \( x \) to the operators and to ask that anticommutators between operators at points \( x, y \) be proportional to \( \delta_{x,y} \) in agreement with the classical bracket. It is easy to see that adding the label \( x \) to (4.28) correctly reproduces this Kronecker symbol and that they satisfy all relations on the Hilbert space.

Finally note that the corresponding scalar product is locally \( SO(D) \) invariant.

5. Generalizations to different multiplets

5.1. Majorana spin-1/2 fermions

The above construction generalizes immediately to Majorana spin-1/2 fermions which are also present in supergravity theories, e.g. \( D + 1 = 9 + 1, N = 2 \) non-chiral supergravity [68]. They are described by actions of the type

\[
S_{\text{Majorana},1/2} = \int d^{D+1}x \bar{\lambda} \gamma^\mu D_\mu \lambda
\]

which, using time gauge and a real representation for the \( \gamma \)-matrices, lead to the canonical brackets \( \{\lambda_\alpha, \lambda_\beta\} \sim i\delta_{\alpha\beta} \) with the reality conditions \( \lambda^* = \lambda \). They can thus also be treated with the above techniques by substituting \( \rho_i \) with \( \lambda \) and removing the \( \bar{\eta}_{IJ} \) projectors.

5.2. Mostly plus/mostly minus conventions

The convention used for the internal signature, i.e. mostly plus or mostly minus and the associated purely real or purely imaginary representations of the \( \gamma \)-matrices, does not interfere with the above construction. The important property we use is the reality of \( i\Sigma_{IJ} \) for \( SO(1, D) \), i.e. that the Gauß constraint is consistent with real spinors. The substitution \( \gamma_I \rightarrow i\gamma_I \) necessary when changing the signature convention does not influence these considerations.

5.3. Weyl fermions

In dimensions \( D + 1 \) even, we also need to consider the case of Weyl fermions. To this end, we define

\[
\gamma_{\text{live}} := i^{D+1+1} \gamma_1 \cdots \gamma_D
\]

(5.2)

13 This corresponds to the quantization rule that the anticommutator is \( +i\hbar \) times the Dirac bracket in the \( \rho \) sector and \( -i\hbar \) times the Dirac bracket in the \( \sigma \) sector. This is the only possible choice of signs because the anticommutator of the same operator which in our case is self-adjoint is a positive operator. The other choice of signs would yield a mathematical contradiction.

14 In the case of the inductive limit, a vector in \( v \in \mathcal{H}_{n_1,\ldots,n_n} \) is embedded in any larger \( \mathcal{H}_{n_1,\ldots,n_1,\ldots,n_1} \) by \( v \mapsto v \otimes \cdots \otimes 1 \) where 1 is the constant polynomial equal to 1. This way any operator at \( x \) acts in a well-defined way on any vector in the Hilbert space.
with the properties $\gamma^2 \varepsilon_{\text{live}} = 1$, $\gamma^\dagger \varepsilon_{\text{live}} = \gamma_{\text{live}}$ and $[\gamma_I, \gamma_{\text{live}}]_+ = 0$ (which follows from our conventions for the gamma matrices $(\gamma^I_0)^2 = -1$, $\gamma^I = 1$, $\gamma^\dagger = \eta_I \gamma_I$). We introduce the chiral projectors
\[
\mathcal{P}^\pm = \frac{1}{2} (1 \pm \gamma_{\text{live}}),
\]
which fulfil the relations $\mathcal{P}^+ \mathcal{P}^\pm = \mathcal{P}^\pm$, $\mathcal{P}^\pm \mathcal{P}^\mp = 0$, $\mathcal{P}^+ + \mathcal{P}^- = 1$ and $(\mathcal{P}\pm)^\dagger = \mathcal{P}^\pm$. These follow directly from the properties of $\gamma_{\text{live}}$.

5.3.1. Spin-1/2 Dirac–Weyl fermions. The kinetic term of the action for a chiral Dirac spinor is given by
\[
S_F = - \int_M d^{D+1}X \left( \frac{i}{2} \bar{\Psi}_\mu \gamma^\mu D_\mu \Psi - \frac{i}{2} \bar{D}_\mu \Psi \gamma^\mu \mathcal{P}^+ \Psi \right).
\]
The 3 + 1 split is performed analogous to [54]. Choosing time gauge, we obtain the non-vanishing Poisson brackets
\[
\{ \Psi^\pm_\alpha, \Pi^\pm_\beta \} = -\mathcal{P}^\pm_{\alpha\beta},
\]
where $\Pi^\pm_\beta := -i(\Psi^\pm)^\dagger_\beta$, and the first-class constraint
\[
\chi_a := \Pi^+_a,
\]
where we used the notation $\Psi^\pm := \mathcal{P}^\pm \Psi$. The first-class property of this constraint follows from the fact that action (5.4) and therefore all resulting constraints do not depend on $\Psi^-$ at all. In the quantum theory, the Hilbert space for the chiral fermions can be constructed similar to the case of non-chiral ones [28]. We obtain a faithful representation of the Poisson algebra by replacing the operators $\hat{\theta}_a$ (acting by multiplication) and $\hat{\theta}_a := \frac{d}{d\theta_a}$ defined in [28] by $\hat{\tilde{\Psi}}^+_a := \mathcal{P}^+_a \hat{\theta}_a$ and $\hat{\tilde{\Psi}}^+_a := \hat{\theta}_a \mathcal{P}^+_a$, as can be seen by
\[
\left[ \hat{\tilde{\Psi}}^+_a, \hat{\tilde{\Psi}}^+_b \right] = \mathcal{P}^+_a \mathcal{P}^+_b.
\]
The reality conditions are implemented if we use the unique measure constructed in [28]. We then have to impose the condition
\[
\hat{\tilde{\Psi}}^+_a f((\theta_a)) = 0,
\]
which restricts the Hilbert space to the functions $\Psi^+_a$ such that $f((\theta_a)) = f((\mathcal{P}^+_a \theta_a))$. Classically, observables do not depend on $\Psi^+_a$. In the quantum theory, they become operators which do not contain $\hat{\tilde{\Psi}}^+_a$ and therefore commute with $\hat{\tilde{\Psi}}^+_a$.

5.3.2. Spin-3/2 Majorana–Weyl fermions. Majorana–Weyl spin-3/2 fermions appear in chiral supergravity theories, e.g., $D + 1 = 9 + 1, N = 1$ [69]. In general, in a real representation ($\gamma^I_0 = \eta_I \gamma_I$) or in a completely imaginary representation ($\gamma^I_0 = -\eta_I \gamma_I$), we have $\gamma_{\text{live}} = (-1)^{\frac{D-1}{2} + 1} \gamma_{\text{live}}$. Therefore, if $\frac{D-1}{2}$ is odd, we have $(\mathcal{P}^\pm)^T = \mathcal{P}^\mp$, and if $\frac{D-1}{2}$ is even, $(\mathcal{P}^\pm)^T = \mathcal{P}^\mp$. In the case at hand ($D = 9$), there exists a real representation and the chiral projectors will be symmetric, $(\mathcal{P}^\pm)^T = \mathcal{P}^\pm$. Again, we will just consider the kinetic term for a chiral Rarita–Schwinger field,
\[
S = \int_M d^{D+1}X i \bar{\psi} \gamma^\mu \gamma^{\nu} \gamma^{\rho} D_\mu \mathcal{P}^+ \psi_\nu \psi_\rho.
\]
The 3 + 1 split is performed like above. We find the second-class constraint $\pi^+_a = \mathcal{P}^+_a \theta_0$ and the first-class constraint $\pi^-_a = 0$. We introduce a second-class partner $\phi^+_a$ for the
first-class constraint. Then we can solve all the constraints using the Dirac bracket
\[
\{ \phi_i^+, \phi_j^+ \}_\text{DB} = -\mathcal{P}^+(C^{-1})_{ij}\mathcal{P}^+,
\]
and all other brackets are vanishing. From here, we can copy the enlargement of the internal space from above, which results in the same theory with all variables projected with \(\mathcal{P}^+\).

(5.10)

(Note that equations like e.g. \(\rho_i^+ = \frac{1}{2}A_{ij}\bar{\eta}^{jk}\mathcal{P}^+(A\rho_k + A^*\rho_k^*) = \frac{1}{2}A_{ij}\bar{\eta}^{jk}(A\rho_k + A^*(\rho^+)_k)\) are consistent. This can be seen by the fact that the matrix \(A(N)\) can be written as an infinite sum of even powers of gamma matrices, \(A(N) \propto \exp(i\Lambda_{ij}(N)\Sigma^{\pm})\) and therefore it commutes with the projectors \(\mathcal{P}^\pm\).) The quantization of the resulting theory with variables \(\rho_i^+, \sigma^+\) is similar to the non-chiral case, with chiral projectors \(\mathcal{P}^\pm\) added in observables, and modifications of the Hilbert space similar to those given above for Dirac–Weyl fermions.

6. Conclusions

In this paper, we have demonstrated that the complications arising when trying to extend canonical supergravity in the time gauge from the gauge group \(\text{SO}(D)\) to \(\text{SO}(D + 1)\) in order to achieve a seamless match to the canonical connection formulation of the graviton sector outlined in [24, 29] can be resolved. Since we worked with a Majorana representation of the \(\gamma\)-matrices, our analysis is restricted to those dimensions where this representation is available, which, however, covers many interesting supergravity theories \((d = 4, 8, 9, 10, 11)\). The price to pay for the enlargement of the gauge group is that the phase space requires an additional normal field \(N\) and that the constraints depend non-trivially on a matrix \(A(N)\) which transforms in a complicated fashion under \(\text{SO}(D + 1)\) but which in the present formulation is crucial in order to formulate the reality conditions for the Majorana fermions in the \(\text{SO}(D + 1)\) theory.

One would expect that the field \(N\) is superfluous and that the matrix \(A(N)\) would simply drop out when performing an extension to \(\text{SO}(1, D)\) because then no non-trivial reality conditions need to be imposed. One would expect that one needs only the quadratic and not the linear simplicity constraint and that, just as it happened in the graviton sector [24, 29], the Hamiltonian phase space extension method simply coincides with the direct Hamiltonian formulation obtained by a \(D + 1\) split of the \(\text{SO}(1, D)\) action followed by a gauge unfixing step in order to obtain a first-class formulation. Surprisingly, this is not the case. The basic difficulty is that when performing the \(D + 1\) split without time gauge, the symplectic structure turns out to be unmanageable. A treatment similar to the one carried out in this paper is possible but turns out to be of similar complexity. It therefore appears that there is no advantage of the \(\text{SO}(1, D)\) extension as compared to the \(\text{SO}(1 + D)\) even as far as the classical theory is concerned. We hope to communicate our findings in a forthcoming publication. Of course, the quantum theory of the \(\text{SO}(1, D)\) extension is beyond any control at this point.

The solution to the tension presented in this paper, between having real Majorana spinors coming from \(\text{SO}(1, D)\) on the one hand and an \(\text{SO}(D + 1)\) extension of the theory which actually needs complex-valued spinors on the other, is most probably far from unique nor the most elegant one. Several other solutions have suggested themselves in the course of our analysis but the corresponding reformulation is not yet complete at this point. Hence, we may revisit this issue in the future and simplify the presentation. Furthermore, it would be interesting to investigate if the extensions of the gauge group \(\text{SO}(D) \to \text{SO}(D + 1)\) also are possible in the case of symplectic Majorana fermions, which would permit access to even more supergravity theories.

To the best of our knowledge, the background-independent Hilbert space representation of the Rarita–Schwinger field presented in section 4 is also new. Apart from the fact that this has to be done for half-density-valued Majorana spinors whose tensor index is transformed
into an external one by contracting with a vielbein, as compared to Dirac spinors there is no representation in terms of holomorphic functions [28] of the Grassmann variables and one has to deal with the non-trivial Dirac bracket.

Appendix. Linear simplicity constraints

As outlined in the main text, the most convenient SO\((D + 1)\) extension of SO\((D)\) Lorentzian supergravity in the time gauge employs a normal vector field \(N\) for which we have to provide the symplectic structure, additional constraints and its interplay with the quadratic simplicity constraint in order to make sure that the physical content of the theory remains unaltered. In effect, the results of [24, 29] are reformulated in terms of a linear simplicity constraint in the spirit of the new spin foam models [70–75]. Therefore, a dynamical unit-length scalar field \(N^i\) will be introduced, which—if the simplicity constraints hold—has the interpretation of the normal to the (spatial pullback of the spacetime \((D + 1)\)) vielbein in the internal (Lorentzian or Euclidean) space. It will be shown that the constraints comprise a first-class system and that the theory in any dimension is equivalent to the ADM formulation of general relativity. The results are shown to extend to coupling of fermionic matter treated in [25]. Like in [24, 29], we can choose either SO\((D + 1)\) or SO\((1, D)\) as a gauge group for Lorentzian gravity. However, only for the compact case, we are able to construct the Hilbert space \(\mathcal{H}_N\) for the normal field \(N^i\). In a companion paper [76], we will comment on the implementation of the linear simplicity constraint operators on the Hilbert space \(\mathcal{H}_T = \mathcal{H}_{\text{grav}} \otimes \mathcal{H}_N\).

A.1. Introductory remarks

In [24, 29], gravity in any dimension \(D\) has been formulated as a gauge theory of SO\((1, D)\) or of the compact group SO\((D + 1)\), irrespective of the spacetime signature. The resulting theory has been obtained by two different routes, a Hamiltonian analysis of the Palatini action making use of the procedure of gauge unfixing\(^\text{15}\) and on the canonical side by an extension of the ADM phase space. The additional constraints appearing in this formulation, the simplicity constraints, are well known. They constrain bivectors to be simple, i.e. the antisymmetrized product of two vectors. Originally introduced in Plebanski’s [80] formulation of general relativity as constrained BF theory in 3 + 1 dimensions, they have been generalized to arbitrary dimension in [81]. Moreover, discrete versions of the simplicity constraints are a standard ingredient of the covariant approaches to loop quantum gravity called spin foam models [82, 72, 74] and recently were also used in group field theory [83]. Two different versions of simplicity constraints are considered in the literature, which are either quadratic or linear in the bivector fields. The quantum operators corresponding to the quadratic simplicity constraints have been found to be anomalous both in the covariant [73] and in the canonical picture [84, 54]. On the covariant side, this leads to one of the major points of critique about the

\(^{15}\) See [77–79] for the original literature on gauge unfixing.
Barrett–Crane model [82]; the anomalous constraints are imposed strongly\(^{16}\), which may imply erroneous elimination of physical degrees of freedom [85]. This leads to the development of the new spin foam models [70–75], in which the quadratic simplicity constraints are replaced by linear simplicity constraints. The linear version of the constraint is slightly stronger than the quadratic constraint, since in \(3+1\) dimensions the topological solution is absent. The corresponding quantum operators are still anomalous (unless the Immirzi parameter takes the values \(\beta = \pm \sqrt{\zeta}\), where \(\zeta\) denotes the internal signature). Therefore, in the new models (parts of), the simplicity constraints are implemented weakly to account for the anomaly.

To make contact with the covariant formulation, it is therefore of interest to ask whether, from the canonical point of view, (a) the theory of [24, 29] can be reformulated using a linear simplicity constraint, and (b) if so, whether the linear version of the constraint can be quantized without anomalies. Both of these questions will be answered affirmatively: the answer to (a) in this appendix and the answer to (b) in our companion paper [76]. As we have shown in the present paper, the use of the linear simplicity constraints (already at the classical level) is probably the most convenient approach towards constructing a connection formulation for supergravity theories in \(D+1\) dimensions with a compact gauge group. To answer (a) we will follow the second route as in [24] and construct the theory with linear simplicity constraint by an extension of the ADM phase space.

Note that the linear constraints already have been introduced in a continuum theory in [86]; yet the considerations there are rather different. The authors reformulate the action of the Plebanski formulation of general relativity using constraints which involve an additional three-form and which are linear in the bivectors, without giving a Hamiltonian formulation. This paper on the other hand deals exclusively with the Hamiltonian framework.

Note that we denote by \((s)\) the spacetime signature and by \((\zeta)\) the internal signature, which can be chosen independently as in [24]. In particular, the gauge group \(\text{SO}(\eta)\) (with \(\eta = \text{diag}(\zeta, 1, 1, \ldots)\)) can be chosen compact, irrespective of the spacetime signature. This will be exploited when quantizing the theory in [76], where we fix \(\zeta = 1\) and therefore do not have to bother with the non-compact gauge group \(\text{SO}(1, D)\). There, we employ the Hilbert space representation for the normal field derived in appendix A.6 of this paper and then we find quantum operators corresponding to the linear simplicity constraint and show that these operators (b) actually are of the first class and therefore can be implemented strongly.

This appendix is organized as follows. Since the construction of the new theory follows neatly the treatment in [24], in appendix A.2 we will shortly review the extensions of the ADM phase space introduced there, highlighting those details which will become important in the case of linear simplicity constraints. In appendix A.3, the new theory is presented and proved to be equivalent to the ADM formulation, which already implies that solving the linear simplicity constraints classically (appendix A.4) leads back to the (extended) ADM phase space and its constraints. Next, we show that the framework can be extended to coupling of fermionic matter (appendix A.5). Finally, we construct a background-independent Hilbert space representation for the normal field \(N^I\) in appendix A.6 which exploits the fact that \(N^I\) on-shell is a unit vector and therefore valued in a compact set.

### A.2. Review: quadratic simplicity constraints

**A.2.1. Step 1: \(\{K_{ab}, \pi^{bkl}\}\) theory.** In [24], the ADM phase space is extended using the variables \(\pi^{alb}\) and \(K_{bkl}\), which are related to the ADM variables via

\[
\pi^{alb}q_{bJ} := 2\zeta q_{J}^{ab},
\]

\(^{16}\)Strongly here means that the constraint operator annihilates physical states, \(\hat{C}|\psi\rangle = 0|\psi\rangle \in \mathcal{H}_{\text{phys}}\).
\[ K^{ab} := -\frac{S}{4\sqrt{q}} \pi^{bKL} K_{cKL} q_a^c (\pi), \]  
\[ P^{ab} = -s \sqrt{q} (K^{ab} - q^{ab} K^c_c) = \frac{1}{4} (q^{ac} (\pi) \pi^{bKL} K_{cKL} - q^{ab} (\pi) \pi^{cKL} K_{cKL}). \]  

The ADM constraints expressed in these variables\(^\text{17}\) are given by

\[ \mathcal{H}_a = -2q_{ac} \nabla_b P^{bc} = -\frac{1}{2} \nabla_b \left( K_{dIJ} \pi^{bIJ} - \delta^b_c K_{dIJ} \pi^{cIJ} \right), \]  
\[ \mathcal{H} = -\left[ \frac{s}{\sqrt{q}} \left( q_{ac} q_{bd} - \frac{1}{D-1} q_{ab} q_{cd} \right) P^{ab} P^{cd} + \sqrt{q} R \right] = -\frac{s}{8\sqrt{q}} \left( \pi^{[aIJ} \pi^{bKL]} K_{dIJ} K_{dKL} \right) - \sqrt{q} R, \]

where \( \nabla_a \) is the covariant derivative annihilating the spatial metric. In order to have the right number of physical degrees of freedom, the Gauß and the (quadratic) simplicity constraints are introduced,

\[ G^{IJ} := 2K^a_a \pi^{aK[I]} J], \]  
\[ S_{IJ}^{ab} := \frac{1}{2} \epsilon^{IJLM} \pi^{aIJ} \pi^{bKL}. \]  

Using the Poisson brackets

\[ \{K_{dIJ}, \pi^{bKL}\} = \delta^b_c \delta^d_f - \delta^d_c \delta^b_f, \]  
\[ \{\pi^{aIJ}, \pi^{bKL}\} = \{K_{dIJ}, \pi^{bKL}\} = 0 \]  

for the extended variables, it has been verified in [24] that the ADM Poisson brackets

\[ \{q_{ab}, q_{cd}\}_{(K, \pi)} \approx 0 \approx \{P^{ab}, P^{cd}\}_{(K, \pi)}, \]  
\[ \{q_{ab}, P^{cd}\}_{(K, \pi)} \approx \delta^{a}_{(c} \delta^{d}_{b)} \]

are reproduced in the extended system up to terms which vanish if constraints (A.6) and (A.7) hold. Actually, only the rotational part of the Gauß constraint (A.6) is needed for the above Poisson brackets to hold. Without going into the details of the calculation (cf [24] for further details), we point out that (A.6) is only needed for \([P, P]\) bracket, where the terms \(K^{a[I} \pi^{b]J]} \approx K^a_a \pi^{aK[I} J]} \pi^{bKL} \) appear (the bar denotes rotational components; see below for notation). This will become important when proving the validity of the theory with linear simplicity constraint in appendix A.3. Since the ADM brackets are recovered, in particular the Dirac algebra of \( \mathcal{H}_a \) and \( \mathcal{H} \) is reproduced in the extended system, the whole system of constraints \( \{\mathcal{H}_a, \mathcal{H}, G^{IJ}, S_{IJ}^{ab}\} \) can easily be shown to be of the first class [24].

For later comparison with the solution of the linear simplicity constraints in appendix A.4, we review the solution of the quadratic simplicity constraints as given in [87, 24]. The solution to the quadratic simplicity constraint is in any dimension given by [81, 24]

\[ \pi^{aIJ} = 2n^I E^{aIJ}, \]  

where \( n^I \) is the unit normal to the vielbein, defined (up to sign) by the equations \( n^I n_I = \zeta \) and \( n_I E^{aIJ} = 0 \). We can use \( n^I \) and the projector \( \eta_{IJ} := n_j - \zeta n_I n_J \) to decompose any bivector \( X_{IJ} \)

\(^{17}\) Note that by calculating the determinant of equation (A.1), we can express both \( q \) and \( q^{ab} \) in terms of \( \pi^{aIJ} \) and via the formula for the inverse matrix we also obtain an expression for \( q_{ab} (\pi) \). All metric-related quantities, like e.g. the Lévi-Civita connection \( \Gamma_{ac}^d \) := \( \frac{1}{2} q^{ed} (\partial_a q_{cd} + \partial_b q_{ad} - \partial_d q_{ab}) \) and the Ricci scalar \( R \), can now be expressed in terms of \( \pi^{aIJ} \) and will automatically be understood as functions of \( \pi^{aIJ} \) in the following. To keep notation simple, the \( \pi^{aIJ} \) dependence will not be made explicit.

27
into its rotational ($\tilde{X}_{IJ} := \tilde{n}^{K}_{I} \tilde{n}^{L}_{J} X_{KL}$) and boost parts ($\tilde{X}_{I} := -\zeta n^{I} X_{I}$) with respect to $n^{I}$. Using (A.10), the symplectic potential reduces to [87]

$$\frac{1}{2} \pi_{aI} R_{aIJ} \approx -\zeta K_{aIJ} E_{aIJ} n^{I}$$

where we have dropped total time derivatives and divergences. The inverse vielbein $E_{aI}$ is defined by the equations $E_{aI} E_{aJ} = \bar{\eta}^{IJ}$ and $E_{aI} E_{bI} = \delta_{ab}$. For the constraints, we find in terms of these variables

$$\frac{1}{2} \lambda_{IJ} G_{IJ} \approx -\lambda_{IJ} E_{aIJ} \partial_{a} \pi_{bI}^{J} K_{aIJ}$$

(A.12)

$$N_{a} H_{a} \approx 2 \zeta \bar{n}^{I} E_{aI} \partial_{a} \pi_{bI}^{J} K_{aIJ}$$

(A.13)

where terms proportional to the Gauß constraint (A.12) as well as total derivatives were dropped in (A.13). Thus, we arrive at an already well-established Hamiltonian formulation of general relativity [87], which leads to the ADM formulation after solving the SO($\eta$) Gauß constraint.

A.2.2. Step 2: \{($\beta$) $A_{aIJ}$, ($\beta$) $\pi_{aIJ}$\} theory. Having this extension of the ADM phase space at our disposal, we can turn it into a connection formulation in a second step. We define the spin connection constructed of the $\pi_{aIJ}$ by

$$\Gamma_{aIJ} := 2 \pi_{bKL} n^{L}_{I} \partial_{a} \pi_{bJ}^{I} + \bar{\eta}^{M}_{I} \bar{n}^{J}_{K} \pi_{bLM} \partial_{a} \pi_{bK}^{I} + \zeta \pi_{bK}^{I} \pi_{bL}^{J} K_{aIJ}^{K}.$$

(A.15)

where we used the abbreviations

$$n^{I}_{J} := \frac{1}{D-1} \left( \pi_{oK}^{I} \pi_{oJ}^{K} - \zeta n^{I}_{J} \right), \quad \bar{n}^{I}_{J} := \eta^{I}_{J} - \zeta n^{I}_{J}, \quad \text{and}$$

$$\pi_{aIJ} := \frac{\zeta}{2} \pi_{aKL} \pi_{bKL}^{I} \left( \pi_{bIJ}^{I} \right)^{-1} n^{I}_{J} = \frac{1}{\delta_{ab}} \pi_{aI}^{I}.$$

(A.16)

One can check that $\Gamma_{aIJ}$ satisfies weakly\(^{18}\) the following identity [24]:

$$\partial_{a} \pi_{aIJ} + [\Gamma_{a}, \pi_{aIJ}] \approx 0.$$  

(A.17)

Moreover, it transforms as a connection under gauge transformations

$$\begin{cases} \Gamma_{aIJ} \approx \partial_{a} \Lambda_{IJ} + [\Gamma_{a}, \Lambda_{IJ}] \end{cases}$$

(A.18)

if the simplicity constraint holds. This suggests the introduction of the following connection variables:

$$\begin{cases} \Gamma_{aIJ} := \Gamma_{aIJ} + \beta K_{aIJ} \quad \text{and} \quad \pi_{aIJ} := \frac{1}{\beta} \pi_{aIJ} \end{cases}$$

(A.19)

\(^{18}\)Note that when solving the simplicity constraint ($\pi_{aIJ} = 2 \omega^{I} E_{aIJ}$), $\Gamma_{aIJ}$ reduces to the hybrid spin connection introduced by Peldan [87] which annihilates $E_{aI}$ (and, since $\omega^{I}$ is a function of $E_{aI}$, also annihilates $n^{I}$). When additionally choosing time gauge $n^{I}_{J} = \delta^{I}_{J}$, the hybrid connection furthermore reduces to the familiar SO($D$) spin connection annihilating the SO($D$) vielbein $E_{aI}$ ($i = 1, \ldots, D$).
with a free parameter\(^{19}\) \(\beta \in \mathbb{R}/\{0\}\) and Poisson brackets given by
\[
\{ (\beta) A_{aIJ}, (\beta) \pi_{bKL} \} = \delta^b_a \delta^K_I \delta^L_J - \delta^L_a \delta^K_I \delta^b_J,
\]
\[
\{ (\beta) \pi_{aIJ}, (\beta) \pi_{bKL} \} = \{ (\beta) A_{aIJ}, (\beta) A_{bKL} \} = 0.
\]
(A.20)

Using equation (A.17), we can rewrite the Gauß constraint to obtain a familiar expression for the generator of gauge transformations
\[
G^{IJ} = 0 + \{ (\beta) K_{a}, (\beta) \pi_{aIJ} \} \approx \partial_a (\beta) \pi_{aIJ} + \{ (\beta) A_{a}, (\beta) \pi_{aIJ} \}.
\]
(A.21)

Now we can repeat the above analysis, again expressing the ADM variables and constraints in terms of the new ones,
\[
(\beta) \pi_{aIJ} = 2 \beta \zeta \delta^b a \delta^K I \delta^L J - \delta^L a \delta^K I \delta^b J,
\]
and checking that the ADM Poisson brackets are reproduced on the extended phase space \(\{ (\beta) A, (\beta) \pi \}\) up to Gauß and (quadratic) simplicity constraints [24].

From the classical point of view, this formulation is a genuine connection formulation of general relativity. In the quantum theory, the quadratic simplicity constraint leads to anomalies both in the covariant [73] and in the canonical approach [29]. Therefore, we want to introduce a linear simplicity constraint in the canonical theory in the following section, inspired by the new spin foam models [70–75].

A.3. Introducing linear simplicity constraints

Recall that the solution to the (quadratic) simplicity constraint in dimensions \(D \geq 3\) is given by [81]
\[
\frac{\epsilon_{aI}}{\beta} = 0 \iff (\beta) \pi_{aIJ} = \frac{2}{\beta} n^I E^{aIJ} \quad \text{and} \quad n^I \text{ is no independent field but determined by the vielbein } E^{aI}.
\]
We now postulate a new field \(N^I\), which will play the role of this normal, together with its conjugate momentum \(P_I\), subject to the linear simplicity and normalization constraints
\[
S_{MN} := \epsilon_{MJKL} N^J (\beta) \pi^{aKL},
\]
\[
N^I := N^I N_I - \zeta.
\]
(A.25)

The solution to the linear simplicity constraints in any dimension \(D \geq 3\) is given by\(^{21}\)
\[
(\beta) \pi^{aIJ} = \frac{3}{2} N^d E^{aIJ}, \quad \text{with } N_d E^{aIJ} = 0.
\]
We see that on the solutions, the physical information of \((\beta) \pi^{aIJ}\) is encoded in the vielbein \(E^{aIJ}\), which in turn fixes the direction of \(N^d\) completely. The remaining freedom in choosing its length is fixed by the normalization constraint \(N\) and we find \(N^d = n^I(E)\), i.e. the \(N^d\) are no physical degrees of freedom. The same has to be assured for the momenta \(P^I\), i.e. we should add additional constraints \(P^d = 0\). However, these extra conditions can be interpreted as (partial) gauge-fixing conditions for (A.25) and (A.26), which then can be removed by applying the procedure of gauge unfixing. We will take a shortcut and

\(^{19}\) Since \(\Gamma_{aIJ}\) is a homogeneous function of degree zero in \(\pi^{aIJ}\) and its derivatives, it is unaffected by the constant rescaling \(\pi^{aIJ} \to \beta (\beta) \pi^{aIJ}\).

\(^{20}\) In \(D = 3\), an additional topological sector exists [81]. The above results hold in \(D = 3\) only if this sector is excluded by hand.

\(^{21}\) Using the linear simplicity constraints, we automatically exclude the topological sector in \(D = 3\).
directly ‘guess’ the theory such that constraints (A.25) and (A.26) are implemented as first class, and we will show that when solving these constraints, the momenta \( P_I \) are automatically removed from the theory.

The theory we want to construct is very similar to the \( \{ \pi^{(\beta)AaIJ}, \pi^{(\beta)\pi^bKL} \} \) theory of appendix A.2.2. It is defined by the Poisson brackets (A.20) and

\[
\{ N^I, P_I \} = \delta^I_J, \quad \{ N^I, N^J \} = \{ P_I, P_J \} = 0, \quad (A.27)
\]

and, apart from the linear simplicity and normalization constraints (A.25) and (A.26), is subject to

\[
G^{IJ} = \frac{1}{2} \frac{(\beta)}{D a} \pi^{aIJ} + P^J N^I, \quad (A.28)
\]

\[
\mathcal{H}_a = \frac{(\beta)}{2} \pi^{bIJ} \partial_a (\pi^{aIJ}) - \frac{(\beta)}{2} \partial_b (\pi^{bIJ}) A_{aIJ} + P^J a_i N^I, \quad (A.29)
\]

\[
\mathcal{H} = -\frac{\beta}{8 \sqrt{q}} (\pi_{aIJ})^b KL (\pi_{bKL}) (\pi_{A - bIJ} (\pi_{A - bKL}) - \sqrt{q} R. \quad (A.30)
\]

Note that the Hamilton constraint is the same\(^{22}\) as in equation (A.24), whereas the Gauß and vector constraints differ and are chosen such that they obviously generate SO(\(\eta\)) gauge transformations and spatial diffeomorphisms respectively on all phase space variables. In the following, we prove its equivalence to the ADM formulation. First of all, we will show that the Poisson brackets of the ADM variables \( K^{ab}, q_{ab} \) in terms of the new variables \( \pi^{(\beta)AaIJ}, \pi^{(\beta)\pi^bKL}, N^I \) and \( P_I \) are still reproduced on the extended phase space up to constraints. This is non-trivial, even if the expressions for \( K^{ab}, q_{ab} \) are given by (A.22) as in the previous section, since we changed both the simplicity and the Gauß constraint. For the linear simplicity and normalization constraints, the solution for \( (\beta)\pi^{aIJ} \) is the same as in the case of the quadratic simplicity (neglecting the topological sector), \( (\beta)\pi^{aIJ} = 2 n^{J} e^{aI} \), and terms which vanished due to the quadratic simplicity constraint still vanish in the case at hand.

For the Gauß constraint, note that the only terms appearing in the calculation are of the form \( (\pi_{A - bIJ} (\pi_{A - bKL}) - \sqrt{q} R \), which already vanish on the surface defined by the vanishing of the rotational parts of the Gauß constraint (cf appendix A.2.1). Now, if the linear simplicity and normalization constraints hold, we know that \( N^I = n^I (E) \), i.e. the modification of the Gauß constraint \( P^I N^J \approx \pi^{IJ} (\pi) \) on-shell just changes the boost part of the Gauß constraint. Thus, the ADM brackets are reproduced on the surface defined by the vanishing of \( G^{IJ}, S^a \), and \( N^I \).

Next, we will show that the algebra is of first class. Note that since \( G^{IJ} \) and \( \mathcal{H}_a \) generate gauge transformations and spatial diffeomorphisms by inspection, their algebra with all other constraints obviously closes. The algebra of the linear simplicity and the normalization constraint is trivial. Moreover, the Hamilton constraint Poisson-commutes trivially with the normalization constraint and, since it depends only on the combination \( \pi^{aIJ} (\pi) A_{aIJ} \), we find \( [\mathcal{H}[N], S^a_{\gamma \delta} [A]^a \gamma \delta] = S^a_{\gamma \delta} [A]^a \gamma \delta] \). We are left with the Poisson bracket between two Hamilton constraints. Since on-shell the ADM brackets are reproduced, the result is

\[
\mathcal{H}[M], \mathcal{H}[N] \approx \mathcal{H}_a^a [q^{ab} (M N^b - N M^b), \quad (A.31)
\]

where \( \mathcal{H}_a^a = -2 q_{ab} \nabla_b P^c \) now denotes the ADM diffeomorphism constraint. As we will see in the next section (appendix A.4), the vector constraint (A.29) correctly reduces to the ADM diffeomorphism constraint if the Gauß and simplicity constraints hold, \( \mathcal{H}_a \approx \mathcal{H}_a^a \). Therefore,

\(^{22}\) In particular, we point out that it is not the Hamilton constraint for gravity coupled to standard scalar fields \( \phi \) which would obtain additional terms \( -\sqrt{q} \nabla^a \phi \phi^a \) for the scalar field \( \phi \) and its conjugate momentum \( p \) which are missing here. In fact, these terms would spoil the constraint algebra, since \( [\mathcal{H}, S^a_{\gamma \delta}] \) and \( [\mathcal{H}, N^I] \) would not vanish weakly.
the algebra closes. What is left to show is that also the Hamilton constraint $H$ on-shell reproduces the ADM constraint, which will be made explicit when solving the constraints in appendix A.4. Note that because of the modified Gauss and simplicity constraints, again this is non-trivial even if $H$ is identical with (A.24).

The counting of the number of physical degrees of freedom goes as follows: the full phase space consists of $|\{A, \pi, N, P\}| = 2^D (2D + 1)^2 + 2^{D+1} (D + 1)^2$ degrees of freedom which are subject to $|\{H_a, H, GIJ, SaI, N\}| = (D + 1) + \frac{D(D+1)}{2} + \frac{D^2(D+1)}{2} + 1$ first-class constraints. It is most convenient to compare this to Peldan’s [87] extended ADM formulation given at the end of appendix A.2.1, with $|\{E, K\}| = 2^D (D + 1)$ phase space degrees of freedom and the first-class constraints $|\{H_a, H, GIJ\}| = (D + 1) + \frac{D(D+1)}{2}$. In any dimension, the difference in phase space degrees of freedom is exactly removed by the simplicity and normalization constraint, $|\{A, \pi, N, P\}| - |\{E, K\}| = 2 |\{S_{\text{GR}}, N\}|$.

We remark that related formulations of general relativity, where a time normal appears as an independent dynamical field, have already appeared in the literature [88–90]. The difference between these and our formulation is that while our formulation features both the simplicity constraint and the time normal at the same time, the time normal appears in the process of solving the simplicity constraint without solving the boost part of the Gauss constraint in the other approaches. In other words, the time normal is an integral part of the simplicity constraint in our approach, not a concept emerging after its solution.

A.4. Classical solution of the linear simplicity constraints

The linear simplicity and normalization constraints can be solved similarly as in appendix A.2.1. As already pointed out in appendix A.3, solving these constraints leads to

$$\beta \pi_{aIJ} = 2 \beta n^l E^{aIJ}$$

and

$$N^l = n^l(E).$$

We make the Ansatz $A_{aIJ} = \Gamma_{aIJ} + \beta K_{aIJ}$ with $\Gamma_{aIJ}$ defined as in (A.15). Then, the symplectic potential reduces to [87]

$$\frac{1}{2} \beta \pi_{aIJ} \beta A_{aIJ} \approx \bar{K}_{aIJ} E^{aIJ} - \bar{K}_{aIJ} E^{aIJ} n^l + \bar{P}_l n^l \approx \left[ \bar{K}_{aIJ} - n_j E_{aIJ} (\bar{K}_{bkl} E^{bkl} + \bar{P}_l) \right] E^{aIJ}$$

$$:= K_{aIJ} E^{aIJ},$$

where we have dropped total time derivatives and divergences. Note that, compared to (A.11), the result is the same up to the additional $\bar{P}_l$ term appearing in the definition of $K_{aIJ}$. For the constraints, we find equal expressions as in (A.12)–(A.14) with $K_{aIJ}$ replaced by $K_{aIJ}$ and again arrive at Peldan’s extended ADM formulation without time gauge [87], which leads to the ADM formulation after solving the $SO(\eta)$ Gauss constraint.

A.5. Linear simplicity constraints for theories with Dirac fermions

In order to incorporate fermions into the framework, tetrads and their higher dimensional analogues (vielbeins) have to be used at the Lagrangian level to construct a representation of the spacetime Clifford algebra. Therefore, the extension of the ADM phase space introduced above is not applicable here. In [25], it is shown that the symplectic reduction of the extension of the phase space $(K_{aij}, E^{aIJ})$ with $SO(D)$ Gauss constraint to $(A_{aij}, \pi^{bKL})$ with $SO(\eta)$ Gauss and (quadratic) simplicity constraints gives back the unextended theory. We may now apply
this fact to theories with fermions. The explicit construction is

\[ \tilde{E}^{al} = \zeta \tilde{\eta}^{al} \pi^{akl} n_k, \quad \tilde{K}^{al} = \zeta \tilde{\eta}^{al} (A - \Gamma)^{akl} n^k, \]  

(A.34)

where \( \Gamma_{al}, \tilde{\eta}_{IJ} \) and \( n^l \) are understood as functions of \( \pi^{IJ} \) (cf [25] for more details).

The extension of \( (\tilde{K}^{al}, \tilde{E}^{al}) \) with \( \text{SO}(D) \) Gauß constraint to \( (A_{al}, \pi^{akl}, N^l, P_J) \) with \( \text{SO}(n) \) Gauß, linear simplicity and normalization constraints works exactly the same way. We can even choose to simplify the replacement of the vielbein and extrinsic curvature using the normal \( N^l \),

\[ \tilde{E}^{al} = \zeta \tilde{\eta}^{al} \pi^{akl} N_k, \quad \tilde{K}^{al} = \zeta \tilde{\eta}^{al} (A - \Gamma)^{akl} n^k, \]  

(A.35)

where \( \tilde{\eta}_{IJ} \) now is understood as a function of \( N^l \). The calculations are completely analogous to those in [25] and therefore will not be detailed here.

### A.6. Kinematical Hilbert space for \( N^l \)

We restrict to the case \( \zeta = 1 \) in the following, because the kinematical Hilbert space for canonical loop quantum gravity has been defined rigorously only for compact gauge groups like \( \text{SO}(D + 1) \). For scalar fields such as the Higgs field, two different constructions to obtain a kinematical Hilbert space have been given. In the first one [28], a crucial role is played by the point holonomies \( U_x(\Phi) := \exp(\Phi(x) x), \) the field \( \Phi^{IJ}, \) which is assumed to transform according to the adjoint representation of \( G \), is contracted with the basis elements \( \tau_{IJ} \) of the Lie algebra of \( G \) and then exponentiated. Point holonomies are better suited for background-independent quantization than the field variables \( \Phi^{IJ} \) themselves, since the latter are real valued rather than valued in a compact set. Therefore, a Gaußian measure would be a natural choice for the inner product for \( \Phi^{IJ} \), but this is in conflict with diffeomorphism invariance [28]. In the case at hand, this framework is not applicable, since \( N^l \) transforms in the defining representation of \( \text{SO}(D + 1) \) and therefore, there is no (or, at least no obvious) way to construct point holonomies from \( N^l \) in such a way that the exponentiated objects transform ‘nicely’ under gauge transformations. The second avenue [66] for background-independent quantization of scalar fields leads to a diffeomorphism invariant Fock representation and can be applied in principle. However, in the case at hand there is a more natural route. On the constraint surface \( \mathcal{N} = N^l n_l - 1 = 0 \), \( N^l \) is valued in the compact set \( S^D \). In this case the measure problems can be circumvented by solving \( \mathcal{N} \) classically. The obvious choice of Hilbert space is then of course the space of square integrable functions on the D-sphere.

To solve \( \mathcal{N} \), we choose a second-class partner \( \hat{\mathcal{N}} := N^l P_l \),

\[ \{N^l(x) N_l(y) - 1, N^l(x) P_l(y)\} = N^l(x) N_l(y) \delta^D(x - y) \approx \delta^D(x - y), \]  

(A.36)

where the terms \( \propto \mathcal{N} \) have been dropped. \( \hat{\mathcal{N}} \) weakly Poisson-commutes with the constraints: it is Gauß invariant and transforms diffeomorphism covariant; it trivially Poisson-commutes with \( \mathcal{H} \) (which neither depends on \( N^l \) nor depends on \( P_l )\), and a short calculation yields

\[ \{S^D_{\mathcal{H}[\varphi]}[\varphi^{\mathcal{H}}], \hat{\mathcal{N}}[\tilde{\varphi}]\} = S^D_{\mathcal{H}[\varphi]}[\hat{\mathcal{N}}[\tilde{\varphi}]]. \]  

(A.37)

Therefore, the algebra of the remaining constraints is unchanged when we solve \( \mathcal{N}, \hat{\mathcal{N}} \) using the Dirac bracket. Let \( \tilde{\eta}_{IJ} = \eta_{IJ} - N_l N_J /||N||^2 \) whence \( \tilde{\eta}_{IJ} N^l = 0 \) also when \( ||N|| \neq 1 \). Then \( \tilde{P}_l = \tilde{\eta}_{IJ} P^J \) Poisson-commutes with the normalization constraint and thus is an observable just as \( N^l \). Since the Dirac matrix is diagonal, the Dirac brackets of \( \tilde{P}_l, N^l \) coincide with their Poisson brackets. We find

\[ \{N^l(x), N_J(y)\}_{DB} = 0, \]

\[ \{N^l(x), \tilde{P}_J(y)\}_{DB} = \tilde{\eta}^{Jl}(x) \delta^D(x - y), \]  

(A.38)

\[ \{\tilde{P}_J(x), \tilde{P}_J(y)\}_{DB} = 2 \tilde{\eta}^{Jl}(x) N_J(x) \delta^D(x - y), \]

\[ \{\tilde{P}_J(x), \tilde{P}_J(y)\}_{DB} = 2 \tilde{\eta}^{Jl}(x) N_J(x) \delta^D(x - y), \]
while the remaining brackets are unaffected. We see that unfortunately the Poisson algebra of the $N^i$ and $\hat{P}_J$ does not close; it automatically generates also the rotation generator $L_{IJ} = 2N^i_JP_J = 2N^iJ\hat{P}_J$. We therefore have to include it into our algebra. On the other hand, obviously $[L_{IJ}, \hat{N}^i] = 0$ so that $L_{IJ}$ is also an observable and moreover the $L_{IJ}$ generate the Lie algebra so$(D + 1)$ while $[L_{IJ}, N^K] = -2N^i_{[J}\delta^K_{I]}$ so that the algebra of the $N^i, L_{IJ}$ already closes. Finally we have the identity $L_{IJ}N^J = -||N||^2\hat{P}_I$ so that the $N^i, L_{IJ}$ already determine $P_I$. We conclude that nothing is gained by considering the $P_I$ and that it is better to consider the overcomplete set of observables $N^i, L_{IJ}$ instead.

Consider, similar as in LQG, the cylindrical functions $F[N]$ of the form $F[N] = F_{p_1\ldots p_n}(N(p_1),\ldots,N(p_n))$ where $F_{p_1\ldots p_n}$ is a polynomial with complex coefficients of the $N^i(p_k), k = 1,\ldots,n$; $I = 0,\ldots,D + 1$. We define the operator $\hat{N}_I(x)$ to be multiplication by $N_I(x)$ on this space. Let also $\Lambda^{IJ}$ be a smooth antisymmetric matrix-valued function of compact support and define the operator

$$\hat{L}[\Lambda] := 2\int d^Dx\Lambda^{IJ}(x)\hat{N}_I(x)\hat{P}_J(x),$$

(A.39)

where $\hat{P}_J(x) = i\partial/\partial N_J(x)$. Note that no factor-ordering problems arise. The operator $\hat{L}[\Lambda]$ has a well-defined action on cylindrical functions, specifically

$$\hat{L}[\Lambda] F[N] = 2\sum_{k=1}^n\Lambda^{IJ}(p_k)\hat{N}_I(p_k)\partial/\partial N_J(p_k) F[N]$$

(A.40)

and annihilates constant functions.

Let $\text{dv}(N) := c_D d^{D+1}\delta(||N||^2 - 1)$ the SO$(D + 1)$ invariant measure on $S^D$ where the constant $c_D$ makes it a probability measure. For a function cylindrical over the finite point set \{p_1,\ldots,p_n\}, we define the following positive linear functional:

$$\mu[F] := \int \text{dv}(N_1)\ldots\text{dv}(N_n) F_{p_1\ldots p_n}(N_1,\ldots,N_n).$$

(A.41)

Just as in LQG it is straightforward to show that the measure is consistently defined and thus has a unique $\sigma$-additive extension to the projective limit of the finite Cartesian products of copies of $S^D$ which in this case is just the infinite Cartesian product \(\mathbb{N} := \prod_{x} S^D\) of copies of $S^D$ \[91\], one for each spatial point. This space can be considered as a space of distributional normals because a generic point in it is a collection of vectors $(N(x))_x$ without any continuity properties. The operator $\hat{N}_I(x)$ is bounded and trivially self-adjoint because $N_I(x)$ is real valued and $S^D$ is compact. To see that $\hat{L}[\Lambda]$ is self-adjoint we let $g_\lambda(p) = \exp(\Lambda^{IJ}(p)\tau_{IJ})$ where $\tau_{IJ}$ are the generators of so$(D + 1)$. We define the operator

$$\hat{U}(\Lambda)F[N] := F_{p_1\ldots p_n}(g_\lambda(p_1)N(p_1),\ldots,g_\lambda(p_n)N(p_n)),$$

(A.42)

which can be verified to be unitary and strongly continuous in $\Lambda$. It may be verified explicitly that

$$\hat{L}[\Lambda] = \frac{1}{i}\left[\frac{d}{d\tau}\right]_{\tau=0}\hat{U}[\Lambda],$$

(A.43)

whence $\hat{L}[\Lambda]$ is self-adjoint by Stone’s theorem \[92\]. Finally it is straightforward to check that besides the *-relations, also the commutator relations hold, i.e. they reproduce $i$ times the classical Poisson bracket.

We conclude that we have found a suitable background-independent representation of the normal field sector.

At each point $p \in \Sigma$, an orthonormal basis in the Hilbert space $\mathcal{H}_p = L_2(S^D, \text{dv})$ is given by the generalizations of spherical harmonics to higher dimensions $\Sigma^k(N)$, which are
shortly introduced in the appendix of our companion paper [76] (see [93] for a comprehensive treatment). An orthonormal basis for $\mathcal{H}_N$ is given by the spherical harmonic vertex functions $F_{\vec{v},\vec{l},\vec{K}}(N) := \prod_{\vec{v} \in \vec{l}} Z_{\vec{v}}^{\vec{K}}(N)$. Any cylindrical function $F_\ell$ can be written as a mean-convergent series of the form

$$F_\ell(N) = \sum_{\vec{l},\vec{K}} a_{\vec{v},\vec{l},\vec{K}} F_{\vec{v},\vec{l},\vec{K}}(N) \quad (A.44)$$

for the complex coefficients $a_{\vec{v},\vec{l},\vec{K}}$. The sum here runs for each $\vec{v} \in \vec{l}$ over all values $l \in \mathbb{N}_0$ and for each $\vec{l}$ over all $\vec{K}$ compatible with $l$. Following the construction in [28], we obtain the combined Hilbert space for the scalar field and the connection simply by the tensor product,

$$\mathcal{H}_T = \mathcal{H}_{\text{grav}} \otimes \mathcal{H}_N = L_2(\mathbb{A}^{SO(D+1)}, d\mu_{\mathcal{A}^{D+1}}) \otimes L_2(\mathcal{N}, d\mu_N).$$

An orthonormal basis in this space is given by a slight generalization of the usual gauge-variant spin-network states (cf., e.g., [28]), where each vertex is labelled by an additional simple $SO(D + 1)$ irreducible representation coming from the normal field. This of course leads to an obvious modification of the definition of the intertwiners which also have to contract the indices coming from this additional representation.
