Preplanned Studies

Two-Week Prevalence of Disease Among the Rural Elderly — 6 Provinces, China, 2018–2019

Tong Xu¹; Hui Han¹

Summary

What is already known about this topic?
As population aging becomes serious in China, the elderly health problems stand out prominently. The 2-week prevalence of the elderly is rising year by year, but it has been rarely studied for the rural seniors in the central and western China.

What is added by this report?
The 2-week prevalence rate of rural elderly in the central and western China is 28.5%, and it varies among different ethnic groups. The top prevalence is chronic diseases, and the severity of diseases is higher in female and high age group (80-year-old and over) people.

What are the implications for public health practice?
Considering the health status, health awareness and ethnic differences of the elderly in the central and western China, medical and health resources should be rationally allocated to prevent and treat chronic diseases and support differentiated health services. This is of great significance for the development of health service plan.

Population aging is a sign of human social progress and an inevitable trend of world population development (1). As the elderly population increases, their health problems become larger concerns to society. The 2-week prevalence of disease is a key indicator reflecting the health status and the demand for health services of the residents surveyed. In this study, the 2-week prevalence of disease among the elderly in central and western China was analyzed to provide a basis for improving the health of the elderly and the quality of health services.

Through multistage random cluster sampling, 14,656 rural elderly people aged 60 years and over in 20 project counties were selected for the survey.

The survey results revealed that the 2-week prevalence of any disease was 28.5%, and the group of disease with the highest prevalence was chronic diseases. An estimated 61.1% of the people surveyed had a chronic disease that continued during the 2-week period. The severity of disease was higher in females than males and higher in the higher age group (aged 80 years or more) than the lower age group (aged 60–79 years).

Thus, the rural elderly population’s health should be protected by preventing chronic diseases and improving access to and quality of medical and health services.

This study was based upon a survey under the “Community Participation to Promote Rural Elderly Health – Phase II” project of China’s National Health Commission. The survey was completed from November 2018 to January 2019 for the elderly aged 60 years and over who were capable of answering the questions on their own and with a residence history exceeding half a year. The participants were selected through multistage random cluster sampling from 130 administrative villages in 65 towns of 20 project counties. These project counties referred to poor counties with a large elderly population and a willingness to be surveyed, and 2–3 towns of each county were selected by random sampling according to the population of the county with 2 villages of each town being selected by random cluster sampling in 6 project regions [provincial-level administrative divisions (PLADs) including Yunnan Province, Xinjiang Uyghur Autonomous Region, Shanxi Province, Qinghai Province, Hubei Province, and Chongqing Municipality].

The survey consisted of face-to-face questionnaire that included two parts: general information of the respondent (e.g. demographic features, health-related conditions, etc.) and 2-week prevalence (e.g. type of 2-week prevalence of disease, onset of 2-week prevalence of disease, and severity of disease). The 2-week prevalence of disease meant that the respondent, within the 14 days before the day when he/she is surveyed: 1) had a disease and visited a medical organization for treatment; 2) had a disease and began self-treatment (e.g. self-administration of drugs, or
adjuvant therapy like hot compress) instead of visiting a medical organization; or 3) had a disease and rested at home or stayed in bed for more than 1 day instead of visiting a medical organization or taking any self-treatment (2).

The 2-week prevalence of disease was defined as the number of persons who had a disease in the past two weeks to the total number of persons surveyed or through a second definition comparing the number person-times suffering a disease in the past two weeks to the total number of persons surveyed. The numerator using the number of persons was adopted in several previous studies and this study, and the additional numerator of person times was used for comparison with the National Health Service Survey data. In this survey, the diseases and the severity were diagnosed based on ICD-10. The types of diseases investigated were subject to the reporting of the respondents.

Statistical analyses were performed using SPSS statistical software (version 22.0, SPSS Inc, Chicago, IL, USA). The significance level was set to \( \alpha = 0.05 \). The statistical method is the chi-square test.

The effective sample size of this survey is 14,656 persons including 7,404 males (50.5\%) and 7,252 females (49.5\%;) and exhibiting an average age of 69.86 ± 6.98 years old (including 8,435 persons or 57.6\% of the total population aged 60 to 69 years) as shown in Table 1.

Among the 14,656 persons, the number of person-times reported to experience disease in the 2 weeks was 4,182, so the 2-week prevalence of disease was derived to be 28.5\%. The number of persons who had an illness in the 2 weeks was 2,546, so the 2-week prevalence was determined to be 17.4\%. Particularly, the 2-week prevalence of disease were 14.9\% for males

### TABLE 1. Basic information and the illnesses over the 2-week study period of the rural elderly — 6 provinces, China, 2018–2019.

| Demographic characteristics | Number of surveyed | Composition ratio (%) | Number of respondents with illnesses | Prevalence (%) | \( \chi^2 \) | \( p \) |
|-----------------------------|--------------------|-----------------------|-------------------------------------|----------------|----------|------|
| Gender                      |                    |                       |                                     |                |          |      |
| Male                        | 7,404              | 50.5                  | 1,102                               | 14.9           |          |      |
| Female                      | 7,252              | 49.5                  | 1,444                               | 19.9           |          |      |
| Age (years old)             |                    |                       |                                     |                |          |      |

| Marital status              |                    |                       |                                     |                |          |      |
| Unmarried/widowed/solitary  | 1,758              | 12.1                  | 287                                 | 16.2           |          |      |
| Only husband and wife living together | 6,566 | 44.8                  | 956                                 | 14.6           |          |      |
| Living with children        | 6,322              | 43.1                  | 1,303                               | 20.6           |          |      |
| Total                       | 14,656             | 100.0                 | 2,546                               | 17.4           |          |      |
and 19.9% for females, and it was the highest (18.9%) in the age group of 80 years and over as shown in Table 1.

The 5 disease categories with the highest 2-week prevalence were hypertension (3.9%), common cold (2.5%), arthritis/rheumatoid (2.3%), gastroenteritis/peptic ulcer (2.1%), and asthma/bronchitis/emphysema and other lung diseases (1.6%). Among the 2,546 persons who reported an illness in the past 2 weeks, 61.1% (1,557/2,546) had a chronic disease which started before the 2 weeks but continued during this period, 25.9% (659/2,546) had an acute disease, and 13.0% (330/2,546) had an acute disease that continued in the 2-week period. See Table 2 for more details.

The severity of disease in the surveyed elderly in the 2 weeks was different between genders and between age groups. The number of sick days in the 2 weeks per 1,000 people was 2,253 days for the lower age group and more than 1,683 days for the higher age group and more than 1,253 days for the lower age group. In addition, the bedridden rate and the number of bedridden days were higher for females than for males, and higher for the higher age group than for the lower age group. See Table 3 for more details.

**DISCUSSION**

The 2-week prevalence was a key indicator that reflected the health status of the elderly and assessed the demand for health services. This survey revealed the 2-week prevalence of disease in elderly people aged 60 years and over in rural areas in central and western China as 28.5% (based on the number of person-times), which is lower than the 2-week prevalence rate of 45.8% in the Fifth National Health Service Survey (2) \((p<0.05)\). This difference was believed to be driven by seasonal factors and the lower availability/quality of health services, weaker health awareness of residents, and other factors in central and western China (3–4).

In view of ethnic groups, the Lahu ethnicity was discovered to have the highest 2-week prevalence of any disease, with the top 5 disease categories being gastroenteritis/peptic ulcer (101.3‰), arthritis/rheumatoid (98.4‰), common cold (74.2‰), intervertebral disc disease (54.2‰), and hypertension (22.8‰). The high prevalence of hypertension may be attributable to the dietary habits of the Lahu people, which includes a relatively high consumption of salt, such as barbecue and pickles as found in our survey. Additionally, the elderly were susceptible to colds, arthritis, and gastrointestinal diseases in the seasonal transition from autumn to winter in Yunnan Province when the survey was performed (5).

The disease category with the highest 2-week prevalence in the rural elderly was chronic diseases such as hypertension. Among the elderly who reported a disease in the surveyed 2 weeks, 61.1% had a chronic disease that continued in the 2-week period. This was similar to the results of most studies, indicating that chronic diseases are the major contributor to the 2-week prevalence of disease (6–9). However, the 2-week prevalence was low in the surveyed regions, possibly because the regions are poor rural areas in central and western China where the living standards of residents are lower and led to a lower prevalence of chronic

| Disease name                                      | Male Prevalence (%) | Male Composition ratio (%) | Female Prevalence (%) | Female Composition ratio (%) | Total Prevalence (%) | Total Composition ratio (%) |
|---------------------------------------------------|---------------------|----------------------------|-----------------------|----------------------------|----------------------|----------------------------|
| Hypertension                                      | 3.3                 | 22.2                       | 4.6                   | 22.9                       | 3.9                  | 22.6                       |
| Cold                                              | 2.0                 | 13.5                       | 3.0                   | 15.0                       | 2.5                  | 14.4                       |

This study was subject to some limitations. The 2-week prevalence obtained in this survey was subject to limitations in the survey method that was time-consuming and covered a large geographical area, which may cause the results to have wide variability. In addition, because this study only covered a period of two weeks, the results may be affected by when the participants were surveyed as they could not all be recorded at the same time.
