Abstract

Introduction: Hypovitaminosis D is a silent but very devastating health issue throughout the world. Some common addictive habits in our country play important role on the issue. The objective of this study was to determine the role of common addictive habits on hypovitaminosis D among the clients attending specialized hospitals. Materials and Methods: This cross-sectional study was conducted among 264 respondents attended Armed Forces Institute of Pathology (AFIP), Dhaka Cantonment for estimation of 25(OH) D within the period of July 2017 to June 2018. Data were collected by face-to-face interview, reviewing with Vitamin D level of the participants from laboratory with the help of a semi-structured questionnaire and checklist respectively. Data were checked, and analyzed with the help of SPSS version 23. Results: Among the respondents, majority (68.56%) were female. The mean ±SD age of the respondents was 48.23 ± 14.05 years. The mean ± SD level of 25(OH)D was 50.01 ± 29.93 nmol/L. Among the males, it was 50.86 ± 28.61 nmol/L and 49.60 ± 26.19 nmol/L among the female. The proportion hypovitaminosis D was 84.84% and a mare difference was found among male and female respondents (84.5% and 85.5% respectively. Smokers (43.88 ± 13.01 nmol/L) were found with lower level of vitamin D than non-smokers (50.88 ± 28.08 nmol/L) (p<0.05).The respondents having habit of chewing betel nut showed lowerlevel of 25 (OH) D than those does not practice that (51.63 ± 18.07 Vs 46.12 ± 13.01 mmol/L). Conclusion: The proportion of hypovitaminosis D was too high. Effective measure to be taken at all level to overcome the nutritional disorder.

Keywords: 25 (OH) D, Smoking, Betel nut, Sun shine.

Introduction

Despite of ample amount of sunshine in Bangladesh vitamin D deficiency is present in a sizeable share of general population which in itself seems to be a paradox. This sub-continent receives a plenty of sunshine all year round and thus people in India should not lack vitamin D. On the contrary, epidemiologic studies from different parts in India reported higher than 70% prevalence of vitamin D deficiency in all age groups, including toddlers, school children, pregnant women and their neonates and adult males. Leading more of an indoor life due to urbanization underlies one of the causes of such deficiency in children brought up in well off families.

With the advance of development and technological improvement it is fact that life expectancy is increasing day by day. Bangladesh is also achieving that in a higher scale. With the age people are suffering from various physical problem. Issues originated from vitamin D deficiency is also playing serious role in our daily life. Though many of our population are suffering from different types of problem including unusual pain, there are very less study conducted on this topic in Bangladesh. A high prevalence of vitamin D deficiency, low dietary intake of calcium was observed in premenopausal Bangladeshi women of both high and low socioeconomic status. Their lifestyle largely confining them to the home and the traditional clothing that Bangladeshi women wear exposes very little of their skin to sunlight. Under these conditions women in different groups are at risk of developing vitamin D deficiency.

Assessment of vitamin D is based on measurement of serum 25(OH)D. Vitamin D deficiency is typically defined as circulating 25 (OH)D concentrations less than 20 ng/mL (50 nmol/L). In this state, the subsequently low ionized calcium concentration stimulates PTH secretion, which eventually leads to increased 25(OH)D synthesis. An insufficient exposure to sunlight is a
and pancreatic cholesterol esterase (pACE), resulting in decreased cholesterol absorption. Areca nut users have aggravated effects of Vitamin D deficiency due to the powerful effect of increased expression of 25(OH)ase, leading to decreased serum calcitriol as areca nut has an independent effect on 25(OH)ase.

Results

The result was based on a sample of 264 adult persons reported to Armed Forces Institute of Pathology (AFIP) under Dhaka cantonment. The data related to addictive habits were recorded and then analyzed through SPSS version 23. Table I shows gender and menopausal state of the respondents. About gender, 68.56% were female and rest were male. Among the female respondents 90 (49.72%) has developed their menopause and rest 91 (50.28%) were in reproductive age group.

Table I: Some demographic data of the respondents.

| Variable                  | Group       | Frequency | Percent |
|---------------------------|-------------|-----------|---------|
| Gender                    | Male        | 83        | 31.44   |
|                           | Female      | 181       | 68.56   |
| Menopausal state (F)      | Menopause   | 90        | 49.72   |
|                           | Non menopause| 91       | 50.28   |

Habit of smoking by the respondents

Among the respondents 241 (91.20%) were nonsmoker and remaining 23 (8.80%) were found smoker (Figure – 1).

Habit of chewing betel nut among the respondents

Among the respondents 231 (87.50%) did not chew betel nut and only 33 (12.50%) had habit of chewing betel nut (Figure – 2).
Table II shows a strong relation between smoking and chance of having hypovitaminosis D. Among the smokers the proportion of hypovitaminosis D was 91.3% (21 out of 29) and among non-smokers it was 84.1% (201 out of 239). This association was statistically significant (p<0.05).

Table III shows a strong relation between taking of betel nut and chance of having hypovitaminosis D. Among those who did not take betel nut their hypovitaminosis D level was 83.5% (193 out of 231). But the persons who used to take betel nut at any amount their proportion was 93.9% (31 out of 33). Those were mainly female populations. This association was statistically significant (p<0.01).

Table IV shows that the mean level of vitamin D was clearly different between two groups of same variable. Respondents bearing habit of chewing betel nut showing less vitamin D than that of non-smokers. Mean vitamin D level was lower among the smoker than that of non-smokers.

Table IV: Relation of addictive habit with mean vitamin D level (n=264).

| Variable                  | Frequency (%) | Mean±SD vit D (nmol/L) | t Score | p Value |
|--------------------------|--------------|------------------------|---------|---------|
| Habit of chewing betel nut |              |                        |         |         |
| Present                  | 33 (12.5%)   | 44.12±13.01            | -2.519  | 0.012   |
| Absent                   | 231 (87.5%)  | 51.62±28.07            |         |         |
| Habit of smoking         |              |                        |         |         |
| Present                  | 230 (87.7%)  | 43.88±13.01            | -1.977  | 0.049   |
| Absent                   | 24 (9.12%)   | 50.88±28.08            |         |         |

Discussion
The present study found 23 (8.71%) as smoker. Among the smokers the proportion of hypovitaminosis D was 91.30% (21 out of 23) and among the non-smokers the proportion was 84.23 (203 out of 241).

Regarding mean value of vitamin D among two groups, there was some differences in serum 25 (OH)D level. The mean±SD level of 25 (OH)D among the smokers was 46.23±13.11 nmol/L and that of non-smokers was 51.02 + 18.88 nmol/L (t, p<0.05) by their study in Athens recommended that smokers had a significantly higher risk of vitamin D deficiency. A cross sectional study was carried out in Copenhagen from June 2012 to May 2014 on sociodemographic determinants of hypovitaminosis D. It was revealed that smoking was associated with higher RR=1.33 (1.02,1.73) for vitamin D deficiency/insufficiency compared with non-smokers.

In this study 33 respondents were found having practice of chewing betel nut. Among those proportion of hypovitaminosis D was remarkably high. The study shows a strong relation between taking of betel nut and chance of having hypovitaminosis D. Among those who did not take betel nut their hypovitaminosis D level was 83.5%. But the persons who used to take betel nut at any amount their proportion was 93.9%. They were mainly female populations. This association was statistically significant (p<0.01). More previous studies have suggested that chewing betel nut may aggravate vitamin D deficiency, since compounds present in betel nut may increase expression of the enzyme 24-hydroxylase, which catalyzes conversion of 1, 25 (OH)2 vitamin D to the relatively inactive 24, 25 (OH)2 vitamin D.

Conclusion
Smoking and Areca nut are the addictive substance consumed in many parts of the world by people of all the age groups also not so uncommon among the people of Bangladesh. Apart from being carcinogenic to the oral cavity, pharynx, esophagus, liver and uterus, it has many diverse effects on the human body affecting almost all the organs. Women who consume areca nut regularly have more incidences of low birth weight and preterm deliveries. Thus, it is evident that these two addictive habits are harmful and affects the whole human body, and its use must be tightly regulated for the welfare of the society.

Conflict of Interests: None.
