Abstract
Potassium is essential macronutrient of plant. It is uptaken by plant through channels and transporters. Plants specie genomes contains a number of KUP/HAK/KT transporters having the primary function to mediate K+ fluxes. In this study, we have identified 13 gene members of KUP/HAK/KT transporter gene family. In most of the plant species, these genes have been characterized but uncharacterized in D. carota. This study has been done to identify KUP/HAK/KT gene family in D. carota plant species to study its phylogeny. This gene family is important for potassium uptake and play an important role in translocation, osmotic potential regulation, plant development and growth. Different tools like MEGA 7.0.21, pfam, SMART and NCBI-BLASTp has been used to characterize the gene family. This study covers the phylogeny and evolution of KUP/HAK/KT transporters in D. carota with reference to A. thaliana.

Keywords: K+ ion; A. thaliana; D. carota; KUP/HAK/KT; Phylogeny

Introduction
Potassium ion (K+) being the essential macronutrient is found very important for various aspects of plant life. In plants, potassium concentration may reach up to 8% of dry cell weight. Potassium is the most plentiful cation that maintains the electrical charge balance and transport of sugar and nitrate in plant cells [1]. It may act as protein synthesis stabilizer or enzyme activator. It is involved in metabolic and physiological processes, such as photosynthesis, cellular osmoregulation and respiration [2]. Potassium deficiency highly affects the plant growth and development as they pertain many abiotic stresses like salt stress, drought stress and cold stress [3]. Potassium is found in bulk amount in earth crust and the uptake of potassium from soil is not as good as it to be because potassium is not in ionic form. The concentration of potassium at root surface is mostly lower than in bulk soil solution which may fall down to µM range. To enhance the potassium uptake, plant have developed various mechanisms for potassium acquisition with >1000-fold concentration gradients [4].

Usually there are two mechanisms for potassium uptake in plants. These are high affinity transporter system via potassium transporters and low affinity potassium transporters via potassium channels. On the basis of function and structure, potassium transporters are divided into five families: 1) shaker channels; 2) TDK (tandem porek; 3) HAK (high affinity K+) /KUP (K+ uptake permease) /KT (K+ transporter); 4) HKT transporters; 5) CPAs (cation proton-antiporters). KUP/HAK/KT is the largest and widely distributed family in bacteria, fungi, and plants. The homology with bacterial KUP and fungal HAK transporters show that the plants KUP/HAK/KT transporter members AtKUP1 and HvHAK1 were first cloned from Arabidopsis and barley. Comparative genomic analysis showed that 13, 27 and 27 KUP/HAK/KT genes were identified in Arabidopsis, Rice and Maize respectively [5]. Mutation analysis has shown that the 8th transmembrane domain and C-terminus of KUP/HAK/KT gene family has a key role in determining the K+ transport capacity. A series of KUP/HAK/KT genes were identified in past decades and a number of physiological roles of these genes were characterized in plant species. At present, KUP/HAK/KT genes have been identified in other species like poplar (Populus trichocarpa), tomato (Solanum lycopersicum), pear (Pyrus bretschneideri) and soybean (Glycine max) [6] (Table 1).

Expression of KUP/HAK/KT is regulated by K+ starvation, abiotic stresses and phytohormones including ABA, cytokinin, ethylene and NAA. These KUP/HAK/KT proteins shows a great variety of subcellular localization in tonoplast, plasma membrane and endoplasmic reticulum. This gene family have role in plant growth and development. The ubiquitous nature of these genes show that they are very important for plants as they help them in survival in potassium poor environment and in nutrients uptake [4].

Daucus carota is a popular taproot vegetable, a plant rich in many bioactive pigments like carotenoids and lutein, cultivated all over the world [7]. Carotenoid found in flowers and fruits of plant playing major role in photosystems of higher plants. It can enhance the pollination ability of plant and seed dispersal activity. It accumulates in carrot taproot being the major nutrient of carrot taproot and also contributes to carrot taproot color [8].

The analysis is done in comparison with the features of this gene family in Arabidopsis. This comprehensive study may provide important information about lineage of KUP/HAK/KT gene family in Daucus carota to other species.

Materials and Methods

Identification and evolutionary analysis of KUP/HAK/KT genes in D. carota

The KUP/HAK/KT potassium transporting genes of D. carota were retrieved from NCBI database (https://www.ncbi.nlm.nih.gov/). The protein sequence of KUP/HAK/KT potassium transporting genes were retrieved from already known protein sequence of potassium transporter genes in A. thaliana. Protein blast (Blastp) was performed against genome database and GenBank to retrieve the protein and DNA sequences of D. carota. A. thaliana gene sequence were used as query sequence against non-redundant protein sequence of D. carota. The retrieved data was manually checked to eradicate the non identical or false positives. The sequences having similarity less than 60% were discarded. Both candidate protein sequences were examined for conserved domains using pfam domain (http://pfam.xfam.org/) [9,10] and SMART (SMART: Main page (embl-heidelberg.de) [11] and sequences were filtered to get finer collection of nonredundant gene sequences present in D. carota. This process was done to eliminate the sequences having no conserved domains. Multiple sequence alignment was done to confirm the conserved domains in the target plant species D. carota. The full length KUP/HAK/KT protein from A. thaliana and D. carota were aligned in MEGA 7.0.21 software and neighbor joining evolutionary tree were constructed with bootstrapping value of 1000 for phylogenetic analysis [12,13]. NCBI database (https://www.ncbi.nlm.nih.gov) was used to recover all genomic information of these potassium transporting genes like exon numbers, chromosomal location of gene, proteina and RNA accession numbers, amino acid length and ORF length.

Gene structure analysis

To predict gene structure and their schematic representation, an online freely available server called Gene Structure Display server (GSDS) was used (http://gds.gao-lab.org/) [14].

Trace the different restriction maps and multiple sequence alignment

Different restriction maps were generated of each sequence by using SerialCloner2-6 software [15]. It generated different graphic maps of each sequence of identifies gene sequence. For multiple sequence alignment, a web-based tool called ClustalW (https://www.genome.jp/tools-bin/clustalw) was used to align the sequence of target specie [16].

Results and Discussions

Identification of KUP/HAK/KT in D. carota and conserved domain profile

The KUP/HAK/KT protein sequences of A. thaliana, C. arietinum and O. sativa (Reference species) were retrieved from NCBI. The retrieved AtKUP/HAK/KT sequences were used in NCBI-BLAST search against D. carota sequence. After making all queries, 13 members of KUP/HAK/KT gene family were identified out of more than 100 sequences and named as 1) DcKUPHAKKT2, 2) DcKUPHAKKT3, 3) DcKUPHAKKT5.1, 4) DcKUPHAKKT5.2, 5) DcKUPHAKKT6.1, 6) DcKUPHAKKT6.2, 7) DcKUPHAKKT6.3, 8) DcKUPHAKKT7.1, 9) DcKUPHAKKT7.1, 10) DcKUPHAKKT8, 11) DcKUPHAKKT10, 12) DcKUPHAKKT11 and 13) DcKUPHAKKT12. The nomenclature was proposed according to functions of homologous Arabidopsis genes. The evolution process tells that the similar structure and similar function of genes arise through replication event and gene duplication is the process which leads towards evolution [17]. The analysis revealed that D. carota contains 13 members of KUP/HAK/KT gene family as in A. thaliana. The AtHAK2, AtHAK6 and AtHAK11 are responsible for salinity response because their...
expression gets affected when salt concentration is increased [1]. Salinity is caused by reduced Na⁺ controlled by AtHKT1 and AtHAK5 which is regulated by external K⁺ concentration [18].

The gene location on the chromosome from top to bottom was analysed. From the analysis, it was analyzed that all of the genes are present on chromosomes having number of 1-9 except 5 and 8. No gene is present on chromosome number 5 and 8. Chromosome location is helpful to find the location of gene on chromosome. Similarly, the exon count analysis reveals that its average range is 8-11, four genes have 9 exons, 4 genes have 8 exons, two genes contain 10 exons and 1 gene contains 11 exons. The presence of K_trans domain in the identified sequence were confirmed using an online tool Pfam (http://pfam.xfam.org/) [10] and SMART (SMART: Main page (embl-heidelberg.de) [19].

Pfam and SMART server searches revealed that the most conserved domain in all sequences is K_trans which show that it belongs to potassium transporter gene family (Table 1 and Table 2).

**Phylogenetic analysis**

To characterize the evolutionary relationship between KUP/HAK/KT gene family of *A. thaliana*, *C. arietinum*, *O. sativa* and *D. carota*, MEGA 7.0.21 was used to generate the rooted tree by the neighbor joining method by the alignment of KUP/HAK/KT from both species (Figure 1). It is concluded that the KUP/HAK/KT gene family is common in almost all plant species. The evolutionary tree showed a close relationship between *O. sativa*, *C. arietinum*, *A. thaliana* and *D. carota*. This gene family helps in mediating the inward transport of K⁺ from Dilute K⁺ solutions as shown in OsHAK1 and OsHAK5 transporters [20]. As the KUP/HAK/KT transporters are multi gene family. For example, Arabidopsis has 13 KUP/HAK/KT genes and Oryza sativa has 27 KUP/HAK/KT genes in total [21]. Investigation shows that KUP/HAK/KT can be divided into four clusters which is confirmed by the phylogenetic analysis of full-length sequences of KUP/HAK/KT transporter gene family. The most studied gene members of KUP/HAK/KT transporter gene family belongs to clusterI and clusterII [22]. ClusterI gene members play essential role in potassium uptake when potassium concentration is low. So, it may be designated as high affinity potassium uptake transporters in *Arabidopsis* which may have the same role in *D. carota* too [4]. Phylogenetic analysis results indicate that evolutionary branches were constant with their assigned gene names. Introns have been found essential traits of eukaryotic gene families during the evolutionary process of multiple gene families [23].
Gene structure analysis

Usually it is found that the position of introns/exons in orthologous genes are commonly well conserved in evolutionary times, but the structure of introns/exons is comparatively less conserved in paralogous genes. To study the structural differences of KUP/HAK/KT gene family we used Gene Structure Display tool (http://gsds.gaoelab.org/) which analyzed the arrangements of introns and exons by comparing CDS sequences and Genomic sequences [24-29]. It shows that DcKUPHAKKT5.2 has more exonic regions than others. In contrast the longest intronic regions are present in DcKUPHAKKT10 and DcKUPHAKKT7.2 gene. The highest exon count is 11 in DcKUPHAKKT11 (Figure 2). It has been reported that AtKUP2 gene plays important role in maintaining cell size. Because K⁺ is the major solute in cell so any diminishing effect to the potassium homeostasis leads to the weakened cell turgor which causes reduction in cell size. Similarly, the gene in D. carota will also affect the cell size [4] (Figure 3).

Mapping Restriction sites

To find the restriction sites of identified sequence, SerialCloner2-6 was used. The genomic sequence of all the 13 gene members were saved in FASTA format and then each sequence was submitted to SerialCloner2-6 software and a graphic map of restriction sites were generated (Figure 4A-D).
Conclusion

Potassium is the macronutrient of plants, it is uptaken by plants through various mechanism. High affinity potassium uptake through Potassium transporter is one of them. This study reported 13 gene members of KUP/HAK/KT potassium transporter gene family in D. carota (wild carrot). This study covers the genomic information, domain prediction, gene structure prediction and phylogenetic analysis. These genes showed a close phylogenetic relationship with A. thaliana, C.arietinum and O. sativa. This gene family is important for potassium transport. Different software like NCBIBLASTp, pfam, SMART and SerialCloner2-6 was used. Gene structure display server software were also used to conduct gene structure analysis. MEGA 7.0.21 software was used to make the phylogenetic tree for evolutionary study.
