IT IS CONSISTENT WITH ZFC THAT $B_1$-GROUPS ARE NOT $B_2$

SAHARON SHELAH AND LUTZ STRÜNGMANN

Abstract. A torsion-free abelian group $B$ of arbitrary rank is called a $B_1$-group if $\text{Bext}^1(B,T) = 0$ for every torsion abelian group $T$, where $\text{Bext}^1$ denotes the group of equivalence classes of all balanced exact extensions of $T$ by $B$. It is a long-standing problem whether or not the class of $B_1$-groups coincides with the class of $B_2$-groups. A torsion-free abelian group $B$ is called a $B_2$-group if there exists a continuous well-ordered ascending chain of pure subgroups, $0 = B_0 \subset B_1 \subset \cdots \subset B_\alpha \subset \cdots \subset B_\lambda = B = \bigcup_{\alpha \in \lambda} B_\alpha$ such that $B_{\alpha+1} = B_\alpha + G_\alpha$ for every $\alpha \in \lambda$ for some finite rank Butler group $G_\alpha$. Both, $B_1$-groups and $B_2$-groups are natural generalizations of finite rank Butler groups to the infinite rank case and it is known that every $B_2$-group is a $B_1$-group. Moreover, assuming $V = L$ it was proven that the two classes coincide. Here we demonstrate that it is undecidable in ZFC whether or not all $B_1$-groups are $B_2$-groups.

Using Cohen forcing we prove that there is a model of ZFC in which there exists a $B_1$-group that is not a $B_2$-group.

1. Introduction

The study of Butler groups, both in the finite and in the infinite rank case, is a most active area of Abelian Group Theory. There are several challenging problems which require deep insight into the theory of Butler groups and the available methods as well as the development of new machinery. The finite rank case is closely related to the study of representations of finite posets while the infinite rank case has its own special flavor. During the last years more and more the connection between infinite rank Butler groups and infinite combinatorics was discovered and led to numerous interesting results. In this paper we discuss one of the long-standing problems, namely whether or not all $B_1$-groups are $B_2$-groups, and show that its solution is independent of ZFC.

All groups in the following are abelian. Recall that a torsion-free group $B$ of finite rank is called a Butler group if it is a pure subgroup of a completely decomposable group of finite rank. Butler [4] introduced this class of groups and proved that being Butler is equivalent to being an epimorphic image of a completely decomposable group of finite rank. For $B_1$-groups and $B_2$-groups, consistency result, Cohen forcing

rank. Later Bican and Salce [4] noticed that a torsion-free group $B$ of finite rank is a Butler group if and only if $\text{Bext}^1(B, T) = 0$ for all torsion groups $T$, where $\text{Bext}^1$ denotes the group of equivalence classes of all balanced exact extensions of $T$ by $B$. This result initiated a generalization of Butler groups to the infinite rank case in two "different" ways: a torsion-free group $B$ of arbitrary rank is called

1. a $B_1$-group if $\text{Bext}^1(B, T) = 0$ for all torsion groups $T$;
2. a $B_2$-group if there exists a continuous well-ordered ascending chain of pure subgroups,

$$0 = B_0 \subset B_1 \subset \cdots \subset B_\alpha \subset \cdots \subset B_\lambda = B = \bigcup_{\alpha \in \lambda} B_\alpha$$

such that $B_{\alpha+1} = B_\alpha + G_\alpha$ for every $\alpha \in \lambda$ for some finite rank Butler group $G_\alpha$.

The authors put the word different in quotation marks on purpose since it was not known whether or not the two definitions 1. and 2. described the same class of torsion-free groups. In fact it is the main aim of this paper to show that it is undecidable in ZFC whether or not $B_1$-groups and $B_2$-groups coincide. This problem is just one among the major questions in the theory of infinite rank Butler groups but we will not touch upon the others in this paper.

Bican and Salce [4] proved that for countable groups the two definitions of $B_1$-group and $B_2$-group coincide and without any cardinality restriction, every $B_2$-group is a $B_1$-group. That the two classes coincide for groups up to cardinality $\leq \aleph_1$ was observed by Dugas-Hill-Rangaswamy [7] and Albrecht-Hill [1]. However, for groups of higher cardinality an affirmative answer needed additional set-theory (e.g. assuming CH the two classes coincide for groups up to cardinality $\leq \aleph_\omega$, see [7]). Several other results were obtained by using $\aleph_0$-prebalanced chains and Axiom-3 families (see [3], [8] and [13]). A very nice result which uses an algebraic, rather than a set-theoretic, condition to ensure that $B_1$-groups are $B_2$-groups is the main result in Fuchs-Rangaswamy [15]:

A $B_1$-group $B$ which is the union of a continuous well-ordered ascending chain of pure subgroups $B_\alpha$ each of which has a countable typeset is necessarily a $B_2$-group.

Assuming the continuum hypothesis Rangaswamy [20] showed that a torsion-free group $B$ is a $B_2$-group if and only if $\text{Bext}^1(B, T) = \text{Bext}^2(B, T) = 0$ for all torsion groups $T$. Thus it was natural to ask whether or not for every torsion-free group $G$, $\text{Bext}^2(G, T) = 0$ for all torsion groups $T$. Under the negation of CH a negative answer was given by Dugas-Thomé [8] while Magidor and the first author [19] answered this question to the negative even assuming the generalized continuum hypothesis. One of the main results on Butler groups of arbitrary cardinality assuming Gödel’s universe of constructability (V=L) can be found in Fuchs-Magidor [14]:

Assuming $V=L$ every $B_1$-group is a $B_2$-group.

In contrast to this result we will show that using Cohen forcing there is a model of ZFC in which there exists a $B_1$-group that is not a $B_2$-group. Hence it is undecidable in ZFC whether or not the two classes of $B_1$-groups and $B_2$-groups coincide.

Our terminology is standard and maps are written on the left. If $H$ is a subgroup of a torsion-free group then the purification of $H$ in $G$ is denoted by $H_\star$. For notations and basic facts we refer to [11] for abelian groups, [8] and [21] for forcing and [3] or [17] for...
set-theory. Moreover, the interested reader may look at [2] for a survey on finite rank Butler groups and at [3], [12] for surveys on infinite rank Butler-groups.

2. Infinite rank Butler groups

In this section we recall the definitions of $B_1$-groups and $B_2$-groups as they were given by Bican-Salce in [5]. Both classes contain the class of finite rank Butler-groups (pure subgroups of completely decomposable groups of finite rank) first studied by Butler in [4]. Let us begin with the notion of a balanced subgroup.

A pure subgroup $A$ of the torsion-free group $G$ is said to be a balanced subgroup if every coset $g + A$ ($g \in G$) contains an element $g + a$ ($a \in A$) such that $\chi(g + a) \geq \chi(g + x)$ for all $x \in A$. Such an element is called proper with respect to $A$ and $\chi(g)$ denotes the characteristic of an element $g$ in the given group $G$.

An exact sequence $0 \to A \to G \to C \to 0$ is balanced exact if the image of $A$ in $G$ is a balanced subgroup of $G$. Hunter [16] discovered that the equivalence classes of balanced extensions of a group $H$ by a group $G$ give rise to a subfunctor $\text{Bext}^1(H,G)$ of $\text{Ext}^1(H,G)$ and hence homological algebra is applicable. Thus for a balanced exact sequence

\[ 0 \to A \to G \to C \to 0 \]  

(*)

and a group $H$ we obtain the two long exact sequences

\[ 0 \to \text{Hom}(C, H) \to \text{Hom}(G, H) \to \text{Hom}(A, H) \to \text{Bext}^1(C, H) \to \text{Bext}^1(G, H) \to \]

\[ \to \text{Bext}^1(A, H) \to \text{Bext}^2(C, H) \to \cdots \]

and

\[ 0 \to \text{Hom}(H, A) \to \text{Hom}(H, G) \to \text{Hom}(H, C) \to \text{Bext}^1(H, A) \to \text{Bext}^1(H, G) \to \]

\[ \to \text{Bext}^1(H, C) \to \text{Bext}^2(H, A) \to \cdots \]

It is routine to check that balanced-exactness of the sequence (*) is equivalent to the following property: for every rank 1 torsion-free group $R$, every homomorphism $R \to C$ can be lifted to a map $R \to G$, i.e. every rank 1 torsion-free group is projective with respect to (*). Thus the following lemma is easily established.

Lemma 2.1. Let

\[ 0 \to A \to G \xrightarrow{\varphi} C \to 0 \]

be a balanced exact sequence. Then this sequence is locally invertible, i.e. for any element $c \in C$ there exists a homomorphism $\psi_c : \langle c \rangle \to G$ such that $\varphi \psi_c = \text{id}_{\langle c \rangle}$.

We now come to the definitions of $B_1$-groups and $B_2$-groups.

Definition 2.2. A torsion-free abelian group $B$ is called

1. a $B_1$-group if $\text{Bext}^1(B, T) = 0$ for all torsion groups $T$;
2. a $B_2$-group if there exists a continuous well-ordered ascending chain of pure subgroups,

$$0 = B_0 \subset B_1 \subset \cdots \subset B_\alpha \subset \cdots \subset B_\lambda = B = \bigcup_{\alpha \in \lambda} B_\alpha$$

such that $B_{\alpha+1} = B_\alpha + G_\alpha$ for every $\alpha \in \lambda$ for some finite rank Butler group $G_\alpha$;

i.e. $B_\alpha$ is descent in $B_{\alpha+1}$ in the sense of Albrecht-Hill [1];

3. finitely Butler if every finite rank subgroup of $B$ is a Butler-group.

Due to Bican-Salce [6] the three definitions are equivalent for countable torsion-free groups.

**Theorem 2.3** ([6]). For a countable torsion-free abelian group $B$ the following are equivalent:

1. $B$ is finitely Butler;
2. $B$ is a $B_2$-group;
3. $B$ is a $B_1$-group.

Without any restriction to the cardinality we have in general:

**Theorem 2.4** ([6]). $B_2$-groups of any rank are $B_1$-groups and finitely Butler.

It turned out that the converse implication in the above theorem couldn’t be proved without any additional set-theoretic assumptions. There are some partial results in ZFC (mentioned in the introduction) characterizing the $B_2$-groups among the $B_1$-groups but none of them is really satisfactory. The following was shown by Fuchs and Rangaswamy independently.

**Lemma 2.5** ([13], [20]). Suppose that $0 \to H \to C \to G \to 0$ is a balanced-exact sequence where $C$ is a $B_2$-group and $H$ and $G$ are $B_1$-groups. If one of $H$ and $G$ is a $B_2$-group, then so is the other.

An attempt to characterize the $B_2$-groups in a homological way is the following theorem due to Fuchs.

**Theorem 2.6** ([13]). If $B$ is a $B_2$-group, then $\text{Bext}^i(B,T) = 0$ for all $i \geq 1$ and for all torsion groups $T$.

Assuming the continuum hypothesis Rangaswamy was able to show that also the converse holds and in some cases Fuchs could even remove CH.

**Theorem 2.7** ([20], [13]). The following is true:

1. Assuming CH a torsion-free group $B$ is a $B_2$-group if and only if $\text{Bext}^1(B,T) = \text{Bext}^2(B,T) = 0$ for all torsion groups $T$. 
2. A torsion-free group $B$ of cardinality $\aleph_n$ (for an integer $n \geq 1$) is a $B_2$-group if and only if $\text{Bext}^i(B, T) = 0$ for all $i \leq n + 1$ and all torsion groups $T$.

Motivated by this result it was natural to ask whether $\text{Bext}^2(B, T)$ is always zero for a torsion-free group $B$ and a torsion group $T$ but Magidor-Shelah [13] proved that this is not the case even assuming the generalized continuum hypothesis GCH. That CH was relevant in many papers was explained by Fuchs who showed the following theorem.

**Theorem 2.8** ([13]). *In any model of ZFC, the following are equivalent:

1. $\text{Bext}^2(G, T) = 0$ for all torsion-free groups $G$ and torsion groups $T$;
2. CH holds and balanced subgroups of completely decomposable groups are $B_2$-groups.

One of the most interesting and main results in the theory of infinite rank Butler groups is the following final theorem of this section proved by Magidor and Fuchs.

**Theorem 2.9** ([14]). *Assuming $V = L$ every $B_1$-group is a $B_2$-group.*

We will show in this paper that the last theorem does not hold in ZFC but is independent of ZFC.

3. **The forcing**

In this section we will explain the forcing notion we are going to use to construct our $B_1$ group $H$ which fails to be $B_2$. The reader who is familiar with forcing, especially with adding Cohen reals may skip this section. Most results are well-known and basic and for unexplained notations and for further results on forcing we refer to Kunen’s book [18] or more advanced to Shelah’s book [21].

Let $M$ be any countable transitive model of ZFC and assume of course that the set theory ZFC is consistent. The aim of forcing is to extend $M$ to a new model which still satisfies ZFC but which has additional properties which we are interested in. Therefore we use the method of forcing which was first discovered by Cohen.

A *forcing notion* $\mathbb{P} \in M$ is just a non empty, partially ordered set $(\mathbb{P}, \leq, 0_\mathbb{P})$, where $0_\mathbb{P}$ is the minimal element of $\mathbb{P}$, hence $0_\mathbb{P} \leq p$ for all $p \in \mathbb{P}$. Note that we don’t require that $p \leq q$ and $q \leq p$ implies $q = p$. If two elements $p, q \in \mathbb{P}$ have no common upper bound, i.e. there is no $t \in \mathbb{P}$ such that $q \leq t$ and $q \leq t$, then we say that $p$ and $q$ are *incompatible* and write $p \perp q$. If a common upper bound exists we call the elements *compatible*. We now want to add to $M$ a subset $G$ of $\mathbb{P}$ to construct a transitive set $M[G]$ which is a model of ZFC with the same ordinals as $M$ such that $M \subseteq M[G]$ and $G \in M[G]$. Those sets $G$ are called generic.

**Definition 3.1.** Let $D \subseteq \mathbb{P}$, $G \subseteq \mathbb{P}$ and $p \in \mathbb{P}$. Then

1. $D$ is called dense in $\mathbb{P}$ if for any $q \in \mathbb{P}$ there is an element $t \in D$ such that $q \leq t$;
2. $D$ is dense above $p$ if for any $q \in \mathbb{P}$, $p \leq q$ there exists an element $t \in D$ such that $q \leq t$;
3. \( G \) is called \( \mathbb{P} \)-generic over \( M \) if the following hold:

(a) for all \( q, r \in G \) there exists \( t \in G \) such that \( q \leq t \) and \( r \leq t \), i.e. all elements of \( G \) are compatible;

(b) if \( q \in G \) and \( t \leq q \) for some \( t \in \mathbb{P} \) then also \( t \in G \);

(c) \( G \cap D \neq \emptyset \) for every dense subset \( D \) of \( \mathbb{P} \) which is in \( M \).

A first observation is that a generic \( G \) intersects also with “dense above \( p \)” sets in many cases.

**Lemma 3.2.** Let \( D \subseteq \mathbb{P} \) and \( G \) be \( \mathbb{P} \)-generic over \( M \). Then

1. Either \( G \cap D \neq \emptyset \) or there exists \( q \in G \) such that for all \( r \in D \) we have \( r \perp q \);
2. If \( p \in G \) and \( D \) is dense above \( p \), then \( G \cap D \neq \emptyset \).

**Proof.** See [18, Lemma 2.20].

If \( G \) is \( \mathbb{P} \)-generic over \( M \) or for short generic, then the existence of the model \( M[G] \) with the desired properties follows from the Forcing Theorem (see [21]). \( M[G] \) is the smallest transitive model of \( ZFC \) that contains \( M \) and \( G \). We don’t want to recall the construction of \( M[G] \) but we would like to mention the following facts. Since we want to prove theorems in \( M[G] \) we would like to know the members of \( M[G] \) but we can not have full knowledge of them inside \( M \) since this would cause these sets to be in \( M \) already. If \( G \) is in \( M \) then \( M[G] \) gives nothing new, so we have to assume that \( G \) is not in \( M \) and this is the case in general as the following lemma shows.

**Lemma 3.3.** Let \( G \) be \( \mathbb{P} \)-generic over \( M \). If \( \mathbb{P} \) satisfies the following condition

(3.1) \[ \forall p \in \mathbb{P} \exists q, r \in \mathbb{P} \text{ such that } p \leq q, p \leq r \text{ and } q \perp r \]

then \( G \notin M \).

**Proof.** See [18, Lemma 2.4].

Nevertheless, every element \( p \) of \( \mathbb{P} \) can be a member of a generic set.

**Lemma 3.4.** Let \( p \in \mathbb{P} \). Then there is a \( G \) which is \( \mathbb{P} \)-generic over \( M \) such that \( p \in G \).

**Proof.** See [18, Lemma 2.3].

Although we don’t know the generic set \( G \) we assume that we have some prescription for building the members of \( M[G] \) out of \( M \) and \( G \). These presinations are called \( \mathbb{P} \)-names, usually denoted by \( \tau \), and their interpretation in \( M[G] \) is \( \tau[G] \). For the exact
IT IS CONSISTENT WITH ZFC THAT $B_1$-GROUPS ARE NOT $B_2$

definition of $\mathbb{P}$-names and their interpretation we refer again to Kunen’s book [18] but let us mention that the Strengthened Forcing Theorem (see [21]) shows that

$$M[G] = \{\tau[G] : \tau \in M \text{ and } \tau \text{ is a } \mathbb{P}\text{-name}\}.$$ 

If we are talking about the $\mathbb{P}$-name of a special object $H$ from $M[G]$ without specifying $G$ then we will write $\bar{H}$ instead of $H$ to avoid confusion but if $H$ is already in $M$, then we omit the snake. Any sentence of our forcing language uses the $\mathbb{P}$-names to assert something about $M[G]$ but the truth or falsity of a sentence $\psi$ in $M[G]$ depends on $G$ in general. If $p \in \mathbb{P}$, then we write $p \Vdash \psi$ and say $p$ forces $\psi$ to mean that for all $G$ which are $\mathbb{P}$-generic over $M$, if $p \in G$, then $\psi$ is true in $M[G]$. If $0_\mathbb{P} \Vdash \psi$ then we just write $\Vdash \mathbb{P} \psi$ which means that for any generic $G$ the sentence $\psi$ is true in $M[G]$ since $0_\mathbb{P}$ is always contained in $G$. Hence the elements of $\mathbb{P}$ provide partial information about objects in $M[G]$ but not all information and if $p \leq q$ then $q$ contains more information than $p$. It is amazing but it may be decided in $M$ whether or not $p \Vdash \psi$ and whenever a sentence $\psi$ is true in $M[G]$ then there is $p \in G$ such that $p \Vdash \psi$.

We now turn to the forcing of adding Cohen reals. Therefore we specify $\mathbb{P}$ and let $\kappa$ be an uncountable cardinal. We put

$$\mathbb{P} = \{p \mid p \text{ is a function from } \kappa \times \omega \text{ to } 2 \text{ with finite domain}\}$$

$$= \{p \mid p : \kappa \times \omega \rightarrow 2, \text{ dom}(p) \text{ finite}\}$$

The partial ordering of $\mathbb{P}$ is given by set theoretic inclusion, i.e. two functions $p$ and $q$ satisfy $p \leq q$ if and only if $q$ extends $p$ as a function. This forcing is called “adding $\kappa$ Cohen reals” and the elements of $\mathbb{P}$ can obviously be regarded as functions from $\kappa$ to $\langle \omega, 2 \rangle$ which we will do in the sequel.

The next lemma shows why the forcing is called adding $\kappa$ Cohen reals.

**Lemma 3.5.** $\Vdash \mathbb{P}$ “There are at least $\kappa$ reals”.

*Proof.* See [21], Chapter I, Lemma 3.3.

We will give the $\kappa$ Cohen reals $\mathbb{P}$-names, say $\bar{\eta}_\alpha$ for $\alpha \in \kappa$ and state some basic properties of the Cohen reals. Note that a real is a function from $\omega$ to $2 = \{0, 1\}$.

**Lemma 3.6.** The following hold for $\alpha, \beta \in \kappa$:

1. $\Vdash \mathbb{P}$ “There are infinitely many $n \in \mathbb{N}$ such that $\bar{\eta}_\alpha(n) = \bar{\eta}_\beta(n) = 1$”;
2. $\Vdash \mathbb{P}$ “There are infinitely many $n \in \mathbb{N}$ such that $\bar{\eta}_\alpha(n) = \bar{\eta}_\beta(n) = 0$”;

3. \(\models P \text{ "There are infinitely many } n \in \mathbb{N} \text{ such that } \tilde{\eta}_\alpha(n) \neq \tilde{\eta}_\beta(n)\)."

Proof. The proof of this fact is standard using a density argument.

Moreover, we have three more important facts.

Lemma 3.7. The following hold for \(P\).

1. \(P\) satisfies the c.c.c. condition, i.e. \(P\) has no uncountable subset of pairwise incompatible members;
2. \(P\) preserves cardinals and cofinalities, i.e. if \(\lambda\) is a cardinal in \(M\), then \(\lambda\) is also a cardinal in \(M[G]\) with the same cofinality;
3. \(\models P \text{ "} 2^{\aleph_0} \geq \lambda \text{". In particular, if } \lambda^{\aleph_0} = \lambda \text{ in } M, \text{ then } \models P \text{ "} 2^{\aleph_0} = \lambda \text{".}\)

Proof. See [21, Chapter I, Lemma 3.8], [21, Chapter I, Theorem 4.1] and [18, Theorem 5.10].

Finally we would like to remark that our notation is the "Jerusalem style" of forcing notation like in [21] but differs from the notation for example in [18]. In our partial order \(p \leq q\) means that \(q\) contains more information than \(p\) does and not vice versa.

4. Our \(B_1\) group \(H\)

Let \(M\) be a countable transitive model of \(ZFC\) in which the generalized continuum hypothesis holds, i.e. \(2^\kappa = \kappa^+\) for all infinite cardinals \(\kappa\). Moreover, let \(\kappa \geq \aleph_4\) be regular and let \(P\) be the forcing of adding \(\kappa\) Cohen reals. As we have seen in the last section, \(P\) preserves cardinals and cofinalities and \(2^{\aleph_0} = \kappa\) in \(M[G]\) for every generic \(G\). Let \(\tilde{\eta}_\alpha\) denote the Cohen reals for \(\alpha \in \kappa\) and let \(M^*\) be a model of the Cohen forcing extending \(M\).

For the definition of our group \(H\) we choose independent elements

\[\{x_n : n \in \omega\} \text{ and } \{y_\alpha : \alpha < \kappa\}\]

and fix a countable set of natural prime numbers

\[\{p_n \in \Pi : n \in \omega\}\]

such that \(p_n < p_m\) for \(n < m\). Here \(\Pi\) denotes the set of all primes.

Definition 4.1. Let \(W = \bigoplus_{n \in \omega} \mathbb{Q}x_n \oplus \bigoplus_{\alpha < \kappa} \mathbb{Q}y_\alpha\) be the rational vector space and let \(F = \bigoplus_{n \in \omega} \mathbb{Z}x_n \oplus \bigoplus_{\alpha < \kappa} \mathbb{Z}y_\alpha\) be the free abelian group generated by the \(x_n\)’s and \(y_\alpha\)’s. Inside \(W\) we define

\[\tilde{H} = \langle F, p_n^{-1}(y_\alpha - x_n) : \alpha < \kappa, n \in \omega, \tilde{\eta}_\alpha(n) = 1 \rangle \subseteq W^+\]
as a subgroup of the additive group $W^+$ of $W$.

Letting $H$ being the interpretation of $	ilde{H}$ in $M^*$ we can now state our Main Theorem.

**Main Theorem 4.2.** In the model $M^*$ the group $H$ is a $B_1$-group but not a $B_2$-group. Hence it is consistent with ordinary set theory ZFC that $B_1$-groups need not be $B_2$-groups.

The proof of the Main Theorem will be divided into two parts. The first part is to show that $H$ is a $B_1$-group which will be done in this section. Section 5 will then consist of proving that $H$ is not $B_2$.

**Theorem 4.3.** In the model $M^*$ the group $H$ is a $B_1$-group.

The proof of Theorem takes the rest of this section and consists of several steps.

**Proof.** (of Theorem 4.3) To prove that $H$ is a $B_1$-group we have to show that $\text{Bext}(H, T) = 0$ for any torsion group $T$. Hence let

(4.2) \[ 0 \to \tilde{T} \xrightarrow{id} \tilde{G} \xrightarrow{\tilde{\varphi}} \tilde{H} \to 0 \]

be a balanced exact sequence with $\tilde{T}$ torsion. Thus there exists $r^* \in \mathbb{P}$ such that

$r^* \models \text{"0 } \to \tilde{T} \xrightarrow{id} \tilde{G} \xrightarrow{\tilde{\varphi}} \tilde{H} \to 0 \text{ is balanced exact."}$

We choose preimages $\tilde{g}_\alpha \in G$ of $y_\alpha$ under $\tilde{\varphi}$ such that $\tilde{\varphi}(\tilde{g}_\alpha) = y_\alpha$ for all $\alpha < \kappa$. Similarly let $\tilde{x}_n \in G$ be a preimage for $x_n$ under $\tilde{\varphi}$ for $n \in \omega$. Moreover, let

$A_\alpha = \{ n \in \omega : \tilde{\eta}_\alpha(n) = 1 \}$

for $\alpha < \kappa$.

It is our aim to show that the balanced exact sequence (4.2) is forced to split, hence it is enough to prove that the homomorphism $\tilde{\varphi}$ is invertible, i.e. we have to find $\tilde{\psi} : \tilde{H} \to \tilde{G}$ such that $\tilde{\varphi}\tilde{\psi} = \text{id}_{\tilde{H}}$. Therefore it is necessary to find preimages of the generators of $\tilde{H}$ in $\tilde{G}$ such that equations satisfied in $\tilde{H}$ also hold in $\tilde{G}$. We need the following definition.

**Definition 4.4.** Let $\alpha < \kappa$ and $\tilde{t} \in \tilde{T}$ arbitrary. Then the set $R_{\alpha, \tilde{t}}$ is defined as

$R_{\alpha, \tilde{t}} = \{ n \in A_\alpha : \tilde{g}_\alpha - \tilde{t} - \tilde{x}_n \text{ is not divisible by } p_n \}$.

We will now use a purely group theoretic argument to show that if for every $\alpha < \kappa$ there is a $\tilde{t}_\alpha \in \tilde{T}$ such that $R_{\alpha, \tilde{t}_\alpha}$ is finite implies that $\tilde{\varphi}$ is invertible.

**Lemma 4.5.** Let $\alpha < \kappa$ and let $\tilde{t} \in \tilde{T}$ such that $R_{\alpha, \tilde{t}}$ is finite. Then there exists $\tilde{t}_\alpha \in \tilde{T}$ such that $R_{\alpha, \tilde{t}_\alpha} = \emptyset$. 
Proof. Since \( R_{\alpha, \bar{t}} \) is finite we may assume without loss of generality that \( R_{\alpha, \bar{t}} \) has minimal cardinality. Assume that \( R_{\alpha, \bar{t}} \) is not empty and fix \( n \in R_{\alpha, \bar{t}} \). By the primary decomposition theorem we decompose \( \bar{T} \) as
\[
\bar{T} = \bar{T}_{p_n} \oplus \bar{T'}
\]
where \( \bar{T}_{p_n} \) denotes the \( p_n \)-primary component of \( \bar{T} \). Since \( n \in A_\alpha \) it follows that \( p_n \) divides \( y_\alpha - x_n \), hence there exists \( \bar{z} \in \bar{G} \) such that
\[
\bar{\varphi}(\bar{z}) = p_n^{-1}(y_\alpha - x_n).
\]
Thus
\[
(\bar{g}_\alpha - \bar{t} - \bar{x}_n) - p_n \bar{z} \in \bar{T} = \bar{T}_{p_n} \oplus \bar{T'}
\]
and therefore there exist \( \bar{t}_0 \in \bar{T}_{p_n} \) and \( \bar{t}_1 \in \bar{T}' \) such that
\[
(\bar{g}_\alpha - \bar{t} - \bar{x}_n) - p_n \bar{z} = \bar{t}_0 + \bar{t}_1.
\]
Since \( \bar{T}' \) is \( p_n \) divisible we can write \( \bar{t}_1 = p_n \bar{t}_2 \) for some \( \bar{t}_2 \in \bar{T}' \). Hence
\[
(\bar{g}_\alpha - \bar{t} - \bar{x}_n) - p_n (\bar{z} - \bar{t}_2) = \bar{t}_0.
\]
We let \( \bar{t}' = \bar{t} + \bar{t}_0 \) and will show that \( R_{\alpha, \bar{t}'} \) has smaller cardinality than \( R_{\alpha, \bar{t}} \) - a contradiction. By the choice of \( \bar{t}' \) we have
\[
(\bar{g}_\alpha - \bar{t}' - \bar{x}_n) = \bar{g}_\alpha - \bar{t} - \bar{t}_0 - \bar{x}_n = p_n (\bar{z} - \bar{t}_2)
\]
and hence \( n \not\in R_{\alpha, \bar{t}'} \). But on the other side, if \( m \not\in R_{\alpha, \bar{t}} \), then \( p_m \) divides \( (\bar{g}_\alpha - \bar{t} - \bar{x}_m) \) and thus \( p_m \) divides \( (\bar{g}_\alpha - (\bar{t}' - \bar{t}_0) - \bar{x}_m) \). Since \( p_n \neq p_m \) it follows that \( p_m \) divides \( \bar{t}_0 \) and therefore \( p_m \) divides \( (\bar{g}_\alpha - \bar{t}' - \bar{x}_m) \). Hence \( m \not\in R_{\alpha, \bar{t}'} \) showing that \( R_{\alpha, \bar{t}'} \) is strictly smaller than \( R_{\alpha, \bar{t}} \). This finishes the proof. \( \square \)

Lemma 4.6. Assume that for every \( \alpha < \kappa \) there exists \( \bar{t}_\alpha \in \bar{T} \) such that \( R_{\alpha, \bar{t}_\alpha} \) is finite. Then \( \bar{\varphi} \) is invertible and hence the sequence (4.2) splits.

Proof. By Lemma 4.3 we may assume without loss of generality that for every \( \alpha < \kappa \) the set \( R_{\alpha, \bar{t}_\alpha} \) is empty. Thus for each \( n \in A_\alpha \) we can find \( \bar{z}_{\alpha, n} \in \bar{G} \) such that
\[
p_n \bar{z}_{\alpha, n} = \bar{g}_\alpha - \bar{x}_n - \bar{t}_\alpha.
\]
We now define a homomorphism \( \bar{\psi} : \bar{H} \to \bar{G} \) as follows:

1. \( \bar{\psi}(x_n) = \bar{x}_n \) \( (n \in \omega) \);
2. \( \bar{\psi}(y_\alpha) = \bar{g}_\alpha - \bar{t}_\alpha \) \( (\alpha < \kappa) \);
3. \( \bar{\psi}(p_n^{-1}(y_\alpha - x_n)) = \bar{z}_{\alpha, n} \) \( (\alpha < \kappa, n \in A_\alpha) \).
It is now easy to check and therefore left to the reader that 1., 2. and 3. induce a well-defined homomorphism \( \tilde{\psi} : \tilde{H} \rightarrow \tilde{G} \) satisfying \( \tilde{\psi} \tilde{\psi} = id_{\tilde{H}}. \)

(Continuation of the proof of Theorem 4.3) Up to now we haven’t used any forcing and we haven’t worked in the model \( M^* \) but in \( M \) itself. By the above Lemma 4.6 it remains to show that there exists for every \( \alpha < \kappa \) an element \( \tilde{t}_\alpha = \tilde{t}_\alpha \in \tilde{T} \) such that the set

\[
R_\alpha, \tilde{t}_\alpha
\]

is finite. To ensure this the forcing comes into the game.

We define for \( \alpha \neq \beta < \kappa \) the pure subgroup \( \tilde{H}_{\alpha, \beta} = \langle y_\beta - y_\alpha \rangle^* \) of \( \tilde{H} \). Since the sequence (4.2) is balanced exact Lemma 2.1 shows that there exist homomorphisms

\[
\tilde{\psi}_{\alpha, \beta} : \tilde{H}_{\alpha, \beta} \rightarrow \tilde{G}
\]

such that \( \tilde{\varphi} \tilde{\psi}_{\alpha, \beta} = id_{\tilde{H}_{\alpha, \beta}}. \)

Let \( \tilde{h}_{\alpha, \beta} = \tilde{\psi}_{\alpha, \beta}(y_\beta - y_\alpha) \in \tilde{G} \), hence

\[
\tilde{t}_{\alpha, \beta} = \tilde{h}_{\alpha, \beta} - (\tilde{g}_\beta - \tilde{g}_\alpha) \in \tilde{T}.
\]

Since \( \tilde{T} \) is a torsion group we can find \( \tilde{m}_{\alpha, \beta} \in \omega \) such that

\[
\text{ord}(\tilde{t}_{\alpha, \beta}) = \tilde{m}_{\alpha, \beta}.
\]

We can now easily show

Fact 4.7. \( r^* \models " \text{If } n > \tilde{m}_{\alpha, \beta}, \text{ then } p_n \text{ divides } (\tilde{g}_\beta - \tilde{g}_\alpha) \text{ for } n \in A_\alpha \cap A_\beta " \)

Proof. If \( n > \tilde{m}_{\alpha, \beta} \), then \( p_n > \tilde{m}_{\alpha, \beta} \) follows since the primes \( p_m \) are increasing. Therefore \( \gcd(p_n, \tilde{m}_{\alpha, \beta}) = 1 \) and thus \( p_n \) divides \( (\tilde{h}_{\alpha, \beta} - (\tilde{g}_\beta - \tilde{g}_\alpha)) \). Moreover, \( \tilde{h}_{\alpha, \beta} = \tilde{\psi}_{\alpha, \beta}(y_\beta - y_\alpha) \) is divisible by \( p_n \) since \( n \in A_\alpha \cap A_\beta \). Hence \( p_n \) divides \( (\tilde{g}_\beta - \tilde{g}_\alpha) \). ■

Now let \( r^* \leq r_{\alpha, \beta} \in P \) such that \( r_{\alpha, \beta} \) forces some value \( m_{\alpha, \beta} \) to \( \tilde{m}_{\alpha, \beta} \), i.e.

\[
r_{\alpha, \beta} \models " \tilde{m}_{\alpha, \beta} = m_{\alpha, \beta} " .
\]

Without loss of generality we assume that \( \beta \in \text{dom}(r_{\alpha, \beta}) \) for all \( \alpha, \beta \). Since all elements of \( P \) are functions from \( \kappa \) to 2 with finite domain, we may write for some \( n_{\alpha, \beta} \in \omega \)

\[
\text{dom}(r_{\alpha, \beta}) = \{ \gamma(\alpha, \beta, 0), \ldots, \gamma(\alpha, \beta, n_{\alpha, \beta}) \} \subset \kappa,
\]

where \( \gamma(\alpha, \beta, i) < \gamma(\alpha, \beta, j) \) if \( i < j \leq n_{\alpha, \beta} \). We would like to apply the \( \Delta \)-Lemma to the functions \( r_{\alpha, \beta} \) to obtain a \( \Delta \)-system but unfortunately the functions \( r_{\alpha, \beta} \) depend on two variables. This forces us to do the \( \Delta \)-Lemma ‘by hand’. For this we use the Erdős-Rado Theorem (see [10]).

First we define a coloring on four tuples in \( \kappa_1 \). Let \( \alpha_0, \alpha_1, \alpha_2, \alpha_3 \in \kappa_1 \) such that \( \alpha_0 \leq \alpha_1 \leq \alpha_2 \leq \alpha_3 \) and let

\[
c(\alpha_0, \alpha_1, \alpha_2, \alpha_3)
\]
consist of the following entries in an arbitrary but fixed order:

(i) \( n_{\alpha_0,\alpha_1} \);
(ii) \( m_{\alpha_0,\alpha_1} \);
(iii) \( r_{\alpha_0,\alpha_1}(\gamma(a_0, a_1, j) : j \leq n_{\alpha_0,\alpha_1}) \);
(iv) \( (tv(\gamma(\alpha_{n_1}, \alpha_{n_2}, n_3) < \gamma(\alpha_{m_1}, \alpha_{m_2}, m_3)) : n_1, n_2, m_1, m_2 < 4; n_3 < n_{\alpha_{n_1},\alpha_{n_2}}; m_3 < n_{\alpha_{m_1},\alpha_{m_2}}) \).

Recall that \( tv \) denotes the truth-value of the inequality and we may assume without loss of generality that it is just Yes or No. The above coloring is a coloring with less than \( \omega \) colors and thus we may apply the Erdős-Rado Theorem. Note that we are still working in our model \( M \) in which GCH holds by assumption. Hence we have

\[ \mathbb{N}_4 \rightarrow (\mathbb{N}_1)^4_{\mathbb{N}_0} \]

which is exactly what we need to apply the Erdős-Rado Theorem. We obtain an increasing chain of \( c \)-homogeneous elements

\[ \Gamma = \{ \alpha_\epsilon : \epsilon < \omega_1 + 1 \} \]

which means that whenever \( \alpha_{\epsilon_1}, \alpha_{\epsilon_2}, \alpha_{\epsilon_3}, \alpha_{\epsilon_4} \in \Gamma \) such that \( \alpha_{\epsilon_1} \leq \alpha_{\epsilon_2} \leq \alpha_{\epsilon_3} \leq \alpha_{\epsilon_4} \), then

\[ c(\alpha_{\epsilon_1}, \alpha_{\epsilon_2}, \alpha_{\epsilon_3}, \alpha_{\epsilon_4}) = c^* \]

for a fixed color \( c^* \). Let this particular color consist of the following entries:

(I) \( n^* \);
(II) \( m^* \);
(III) \( (k_1, \cdots, k_{n^*}) (k_i \in \{0, 1\}) \);
(IV) \( (l_1, \cdots, l_{16^2(n^*)^2}) (l_i \in \{\text{Yes, No}\}) \).

Let us first explain what the homogenity implies. Let \( \alpha_{\epsilon_1}, \alpha_{\epsilon_2} \in \Gamma \) such that \( \epsilon_1 < \epsilon_2 \), then (I) ensures that the domain of \( r_{\alpha_{\epsilon_1},\alpha_{\epsilon_2}} \) has size \( n^* \). Moreover, (II) says that \( r_{\alpha_{\epsilon_1},\alpha_{\epsilon_2}} \) forces the value \( m^* \) to \( m_{\alpha_{\epsilon_1},\alpha_{\epsilon_2}} \) and (III) implies that the image of \( r_{\alpha_{\epsilon_1},\alpha_{\epsilon_2}} \) is uniquely determined. Finally (IV) ensures that if we take another pair \( \alpha_{\epsilon_3}, \alpha_{\epsilon_4} \in \Gamma \) such that \( \epsilon_3 < \epsilon_4 \), then the relationship between the elements of the domains of \( r_{\alpha_{\epsilon_1},\alpha_{\epsilon_2}} \) and \( r_{\alpha_{\epsilon_3},\alpha_{\epsilon_4}} \) is fixed.

In the sequel we need to be above all the ”trouble”, hence we may assume without loss of generality that \( m^* \) is greater or equal to \( \text{length}(r_{\alpha_{\epsilon},\alpha_\rho}(\gamma(\alpha_{\epsilon},\alpha_\rho, e))) \) for all \( \epsilon < \rho < \omega_1 \) and \( e \leq n^* \). We can now approach to the \( \Delta \)-Lemma.

**Definition 4.8.** For \( \alpha_\epsilon \in \Gamma \) we define

(1) \( u_{\alpha_\epsilon} = \text{dom}(r_{\alpha_\epsilon,\alpha_{\epsilon+1}}) \cap \text{dom}(r_{\alpha_\epsilon,\alpha_{\epsilon+2}}) \);
IT IS CONSISTENT WITH ZFC THAT $B_1$-GROUPS ARE NOT $B_2$

(2) $u^* = \bigcap_{\epsilon < \omega_1} u_{\alpha_\epsilon}$;

(3) $s_\epsilon = r_{\alpha_\epsilon, \alpha_{\epsilon+1}} | u_{\alpha_\epsilon} = r_{\alpha_\epsilon, \alpha_{\epsilon+2}} | u_{\alpha_\epsilon}$.

The reader might ask why (3) in the above Definition 4.8 is well-defined. This follows from homogeneity since (II) implies that for $\gamma \in u_{\alpha_\epsilon}$ we have $r_{\alpha_\epsilon, \alpha_{\epsilon+1}}(\gamma) = r_{\alpha_\epsilon, \alpha_{\epsilon+2}}(\gamma)$.

We are now ready to show the following lemma, our version of the $\Delta$-system. Note that if we talk about a $\Delta$-system of functions then we mean that the corresponding domains of the functions form a $\Delta$-system.

Lemma 4.9. For $\alpha_\epsilon, \alpha_\rho \in \Gamma$ such that $\epsilon < \rho$ we have

$$u_{\alpha_\epsilon} \cap u_{\alpha_\rho} = u^*.$$  

Hence the functions $s_\epsilon$ ($\alpha_\epsilon \in \Gamma$) form a $\Delta$-system with root $u^*$. Moreover, for fixed $\epsilon < \omega_1$ the functions $r_{\alpha_\epsilon, \alpha_\rho}$ ($\epsilon < \rho < \omega_1$) form a $\Delta$-system with root $u_{\alpha_\epsilon}$.

Proof. Let $\alpha_\epsilon, \alpha_\rho \in \Gamma$ such that $\epsilon < \rho$. Clearly we have $u^* \subseteq u_{\alpha_\epsilon} \cap u_{\alpha_\rho}$ by Definition 4.8. It remains to show the converse inclusion. Therefore let $\gamma \in u_{\alpha_\epsilon} \cap u_{\alpha_\rho}$ and choose $\tau < \omega_1$ arbitrary. We have to prove that $\gamma$ lies in $u_{\alpha_\tau}$.

If $\tau = \epsilon$ or $\tau = \rho$, then we are done.

If $\tau \geq \epsilon + 1$, then $c(\alpha_\epsilon, \alpha_{\epsilon+1}, \alpha_\tau, \alpha_{\tau+1}) = c^*$ by homogeneity. Since $\gamma \in \text{dom}(r_{\alpha_\epsilon, \alpha_{\epsilon+1}})$ we can find $i \leq n^*$ such that $\gamma = \gamma(\alpha_\epsilon, \alpha_{\epsilon+1}, i)$ and similarly $\gamma = \gamma(\alpha_\rho, \alpha_{\rho+1}, j)$ for some $j \leq n^*$.

It follows now that

$$tv(\gamma(\alpha_\epsilon, \alpha_{\epsilon+1}, i) < \gamma(\alpha_\rho, \alpha_{\rho+1}, j)) = \text{No} \text{ and } tv(\gamma(\alpha_\rho, \alpha_{\rho+1}, j) < \gamma(\alpha_\epsilon, \alpha_{\epsilon+1}, i)) = \text{No}.$$  

Hence there exists by homogeneity $k \leq n^*$ such that

$$tv(\gamma(\alpha_\epsilon, \alpha_{\epsilon+1}, i) < \gamma(\alpha_\tau, \alpha_{\tau+1}, k)) = \text{No} \text{ and } tv(\gamma(\alpha_\tau, \alpha_{\tau+1}, k) < \gamma(\alpha_\epsilon, \alpha_{\epsilon+1}, i)) = \text{No}.$$  

Thus $\gamma = \gamma(\alpha_\tau, \alpha_{\tau+1}, k) \in \text{dom}(r_{\alpha_\tau, \alpha_{\tau+1}})$. Similarly it follows that $\gamma \in \text{dom}(r_{\alpha_\tau, \alpha_{\tau+2}})$ and hence $\gamma \in u_{\alpha_\tau}$ which was to prove.

If $\tau < \epsilon + 1$, then we use similar arguments to those above to prove that $\gamma \in u_{\alpha_\tau}$.

Thus we have shown that $\gamma \in u_{\alpha_\tau}$ for any $\tau < \omega_1$ and therefore $\gamma \in u^*$.

The same kind of arguments show that also the functions $r_{\alpha_\epsilon, \alpha_\rho}$ ($\epsilon < \rho < \omega_1$) form a $\Delta$-system with root $u_{\alpha_\epsilon}$ for fixed $\epsilon < \omega_1$.  

It is now easy to see by a pigeon-hole argument that we may assume without loss of generality (and we will assume this in the sequel) that all the functions from the $\Delta$-systems in Lemma 4.9 coincide on their root.

(Continuation of the proof of Theorem 4.3) The following definition now makes sense.
Definition 4.10. For $\epsilon < \rho < \omega_1$ and a generic $G \subseteq \mathbb{P}$ we define

(I) $s^* = s_\epsilon \upharpoonright u^* = s_\epsilon \upharpoonright (u_\alpha \cap u_\rho)$;
(II) $\tilde{Y} = \{ \alpha_\tau : s_\tau \in G \}$.

We can now show that $s^*$ is strong enough to force that $\tilde{Y}$ has cardinality $\aleph_1$.

Fact 4.11. $s^* \vDash " | \tilde{Y} | = \aleph_1 "$

Proof. Let $\tilde{Y}' = \{ s_\epsilon : \alpha_\epsilon \in \Gamma \backslash \tilde{Y} \}$ and assume that $s^*$ does not force $\tilde{Y}$ to be of size $\aleph_1$. Then $| \tilde{Y}' | = \aleph_1$. We will show that this set is pre-dense above $s^*$. Therefore let $f \geq s^*$, then $\text{dom}(f)$ is a finite subset of $\kappa$ and $u^* \subseteq \text{dom}(f)$. We choose $s_\epsilon \in \tilde{Y}'$ such that $\text{dom}(s_\epsilon) \backslash u^*$ is disjoint to $\text{dom}(f) \backslash u^*$. This is possible since by Lemma 4.9 the $s_\epsilon$'s form a $\Delta$-system, hence

$$\text{dom}(s_\tau) \backslash u^* \cap \text{dom}(s_\beta) \backslash u^* = \emptyset$$

for $\beta \neq \tau$. Now, $f$ and $s_\epsilon$ are compatible and thus $\tilde{Y}'$ is pre-dense above $s^*$. Therefore $\tilde{Y}' \cap G \neq \emptyset$ by Lemma 3.2 - a contradiction. ■

We are almost done now and prove the following statement.

Fact 4.12. $s^* \vDash " \text{If } \alpha_\epsilon, \alpha_\rho \in \tilde{Y} \text{ and } n \in A_{\alpha_\epsilon} \cap A_{\alpha_\rho} \backslash [0, m^*] \text{ then } p_n \text{ divides } g_{\alpha_\epsilon} - g_{\alpha_\rho} "$.

Proof. Let $s^* \leq s$ such that

$$s \vDash " n \in A_{\alpha_\epsilon} \cap A_{\alpha_\rho} \backslash [0, m^*] " .$$

Without loss of generality we may assume that $s$ also forces truth values to $\alpha_\epsilon \in \tilde{Y}$ and $\alpha_\rho \in \tilde{Y}$. If one of them is No, then we are done and hence let us assume that both are Yes. We will show that there exists $\gamma < \omega_1$ such that

(I) $\gamma > \epsilon$;
(II) $\gamma > \rho$;
(III) $\text{dom}(r_{\alpha_\epsilon, \alpha_\gamma}) \backslash u_{\alpha_\epsilon} \cup \text{dom}(r_{\alpha_\rho, \alpha_\gamma}) \backslash u_{\alpha_\rho} \cup \{ \alpha_\gamma \} \cup u_{\alpha_\gamma} \backslash u^* \text{ is disjoint to } \text{dom}(s)$.

Obviously we can choose $\gamma > \epsilon, \rho$ such that $\text{dom}(s)$ is disjoint to $\{ \alpha_\gamma \}$, so all we have to ensure is that also $\text{dom}(r_{\alpha_\epsilon, \alpha_\gamma}) \backslash u_{\alpha_\epsilon} \cup \text{dom}(r_{\alpha_\rho, \alpha_\gamma}) \backslash u_{\alpha_\rho} \cup u_{\alpha_\gamma} \backslash u^*$ is disjoint to $\text{dom}(s)$.

For this we prove that the three sets

(1) $\{ \gamma < \omega_1 : \text{dom}(r_{\alpha_\epsilon, \alpha_\gamma}) \backslash u_{\alpha_\epsilon} \text{ is not disjoint to } \text{dom}(s) \}$;
(2) $\{ \gamma < \omega_1 : \text{dom}(r_{\alpha_\rho, \alpha_\gamma}) \backslash u_{\alpha_\rho} \text{ is not disjoint to } \text{dom}(s) \}$;
(3) $\{ \gamma < \omega_1 : u_{\alpha_\gamma} \backslash u^* \text{ is not disjoint to } \text{dom}(s) \}$. 

are bounded in \( \omega_1 \). Let us start with (1). By Lemma 4.9 we know that for each \( \epsilon < \omega_1 \) the domains \( \{ \text{dom}(r_{\alpha,\alpha}) : \epsilon < \gamma < \omega_1 \} \) form a \( \Delta \)-system with root \( u_{\alpha,\epsilon} \), hence \( \{ \text{dom}(r_{\alpha,\alpha}) \setminus u_{\alpha,\epsilon} \} \) is a set of pairwise disjoint sets. Since \( \text{dom}(s) \) is a finite set \( \{ \gamma < \omega_1 : \text{dom}(r_{\alpha,\alpha}) \setminus u_{\alpha,\epsilon} \text{ is not disjoint to } \text{dom}(s) \} \) must be bounded in \( \omega_1 \). Similarly \( \{ \gamma < \omega_1 : \text{dom}(r_{\alpha,\alpha}) \setminus u_{\alpha,\rho} \text{ is not disjoint to } \text{dom}(s) \} \) is bounded in \( \omega_1 \). Finally, again by Lemma 4.9 the sets \( \{ u_{\alpha,\gamma} : \gamma < \omega_1 \} \) form a \( \Delta \)-system with root \( u^* \) and so also \( \{ \gamma < \omega_1 : u_{\alpha,\gamma} \setminus u^* \text{ is not disjoint to } \text{dom}(s) \} \) is bounded in \( \omega_1 \).

For this \( \gamma \) we are able to prove that there is \( s^+ \geq s \) such that

1. \( s^+ \geq s \);
2. \( s^+ \models \text{"} \eta_{\alpha,\gamma}(n) = 1 \text{"} \);
3. \( s^+ \geq r_{\alpha,\gamma} \geq r_{\alpha,\alpha,\gamma} \);
4. \( s^+ \geq r_{\alpha,\alpha,\gamma} \).

Since \( n \) was chosen large enough which means that \( \eta_{\alpha,\gamma} \) has length less or equal to \( m^* \) and hence less or equal to \( n \), there is, once we know that we can satisfy (i), (iii) and (iv), also some \( s^+ \geq s \) satisfying all conditions (i), (ii), (iii) and (iv). Thus we only have to satisfy conditions (ii), (iii) and (iv) and for this it is obviously enough to show that the three functions \( s, r_{\alpha,\alpha,\gamma} \) and \( r_{\alpha,\alpha,\gamma} \) are compatible. Assume that \( r_{\alpha,\alpha,\gamma} \) and \( r_{\alpha,\alpha,\gamma} \) are incompatible, then by induction we obtain that \( r_{\alpha,\alpha,\omega_1} \) and \( r_{\alpha,\alpha,\omega_1} \) are incompatible. Hence for \( \tau < \sigma < \omega_1 \) we have that \( r_{\alpha,\alpha,\omega_1} \) and \( r_{\alpha,\alpha,\omega_1} \) are incompatible which contradicts the c.c.c. condition of our forcing. Therefore \( r_{\alpha,\alpha,\gamma} \) and \( r_{\alpha,\alpha,\gamma} \) are compatible. Finally \( s \) and \( r_{\alpha,\alpha,\gamma} \) (and similarly \( s \) and \( r_{\alpha,\alpha,\gamma} \)) are compatible since by the choice of \( \gamma \) we have \( \text{dom}(s) \cap \text{dom}(r_{\alpha,\alpha,\gamma}) = u_{\alpha,\gamma} \).

Now \( s^+ \models \text{"} p_n \text{ divides } g_{\alpha,\gamma} - g_{\alpha,\rho} \text{"} \) and \( s^+ \models \text{"} p_n \text{ divides } g_{\alpha,\gamma} - g_{\alpha,\rho} \text{"} \) and therefore \( s^+ \models \text{"} p_n \text{ divides } g_{\alpha,\gamma} - g_{\alpha,\rho} \text{"} \) as claimed.\[\]

Finally we have to prove another fact.

**Fact 4.13.** \( s^* \models \text{"} \) For every \( \beta < \kappa \) there exists \( m_\beta < \omega \) such that \( \forall m_\beta < n \in A_\beta \) and \( \alpha \in \tilde{Y} \) such that \( n \in A_\alpha \) we have \( p_n \text{ divides } g_\beta - g_\alpha \) \( \text{"} \).

First note that this implies that the set \( R_{\beta,0} \) is contained in \( [0, m_\beta) \) for all \( \beta < \kappa \) and hence finite after modifying the choice of the preimages \( \tilde{x}_n \) of \( x_n \) \( (n \in \omega) \) slightly (which doesn’t has any effect on what we have done so far). Choose \( \tilde{x}_n \in \tilde{G} \) such that

1. \( \varphi(\tilde{x}_n) = x_n \);
2. if \( n > m^* \) and \( \alpha \in \tilde{Y} \) such that \( \eta_\alpha(n) = 1 \), then \( p_n \text{ divides } g_\alpha - \tilde{x}_n \).\[\]
For example if $n > m^*$ we choose $\alpha \in \bar{Y}$ such that $\eta_\alpha(n) = 1$; Let $k_n \in \bar{G}$ such that $\varphi(k_n) = 1/p_n(y_\alpha - x_n)$ and put $\bar{x}_n = p_n k_n + g_\alpha$. Then clearly (i) and (ii) are satisfied.

Now Fact 4.13 ensures that $R_{\beta,0}$ is contained in $[0,m_\beta)$ because: For $m_\beta < n \in A_\beta$ choose $\alpha_\epsilon \in \bar{Y}$ such that $\eta_{\alpha_\epsilon}(n) = 1$ (the one which was used when choosing the $\bar{x}_n$’s), then we have by the choice of $\bar{x}_n$ that $p_n$ divides $g_{\alpha_\epsilon} - \bar{x}_n$ and hence $p_n$ divides $g_{\beta} - \bar{x}_n$. Thus $n \not\in R_{[\beta,o)}$ and $R_{[\beta,0)} \subseteq [0,m_\beta)$ follows.

Therefore the proof of Fact 4.13 finishes the proof of Theorem 4.3.

Proof. Fix $\beta < \kappa$ and let $s^+ < s$ such that $s$ forces $n \in A_\beta$. For every $\epsilon < \omega_1$ we choose (if possible) $t^\epsilon_\beta$ in the generic set such that

\begin{enumerate}
  \item[(i)] $s \leq t^\epsilon_\beta$;
  \item[(ii)] $t^\epsilon_\beta \Vdash "\alpha_\epsilon \in \bar{Y}"$;
  \item[(iii)] $t^\epsilon_\beta \Vdash "m_{\alpha_\epsilon,\beta} = m^\epsilon_{\alpha_\epsilon,\beta}"$ for some $m^\epsilon_{\alpha_\epsilon,\beta} \in \mathbb{N}$.
\end{enumerate}

Note that it is sufficient to find one $\epsilon$ s.t.

\begin{equation}
  p_n \text{ divides } g_{\beta} - g_{\alpha_\epsilon}
\end{equation}

, for then we can use fact 1.12 to get the conclusion for any $\alpha_\rho$ s.t. $n \in A_{\alpha_\rho}$. If we have one $t^\epsilon_\beta$ satisfying (ii) and (iii), then it forces (\ast) for $n > m^\epsilon_{\alpha_\epsilon,\beta}$. So we first ensure (ii) and (iii) and then we use that there is an uncountable subset $S_{\beta}$ of $\omega_1$ such that \{ $t^\epsilon_\beta : \epsilon \in S_{\beta}$ \} is a $\Delta$-system to ensure (i) where we put $m_\beta = m^\epsilon_{\alpha_\epsilon,\beta}$ which can be chosen fixed for the $\Delta$-system.

\section{Why $H$ fails to be $B_2$}

To complete the proof of our Main Theorem 4.2 we show in this section that the interpretation $H$ of the group $\tilde{H}$ from Definition 4.1 can not be a $B_2$-group in $M^*$.

\begin{theorem}
  In the model $M^*$ the group $H$ can not be a $B_2$-group.
\end{theorem}

\begin{proof}
  Towards contradiction assume that $H$ is a $B_2$-group, hence has a $B_2$-filtration

  \[ H = \bigcup_{\alpha < \kappa} H_\alpha. \]

  Recall that a $B_2$-filtration is a smooth ascending chain of pure subgroups $H_\alpha$ such that for every $\alpha < \kappa$ $H_{\alpha+1} = H_\alpha + B_\alpha$ for some finite rank Butler group $B_\alpha$. We need the following lemma and recall that a cub in $\kappa$ is a subset $C$ of $\kappa$ such that

  \begin{enumerate}
    \item[(i)] $C$ is closed in $\kappa$, i.e. for all $C' \subseteq C$, if $\text{sup } C' < \kappa$, then $\text{sup } C' \in C$;
  \end{enumerate}

(ii) $C$ is unbounded in $\kappa$, i.e. $\sup C' = \kappa$.

The proof of the following lemma is standard (see [3][II.4.12]) but for the convenience of the reader we include it briefly.

**Lemma 5.2.** The set $C = \{ \delta < \kappa \mid H_\delta = \langle x_n, y_\beta : n \in \omega, \beta < \delta \rangle_\ast \}$ is a closed unbounded set (cub) in $\kappa$.

**Proof.** First we show that $C$ is closed in $\kappa$. Therefore let $C' = \{ \delta_i \mid i \in I \}$ be a subset of $C$ such that $\sup C' < \kappa$. If we put $\gamma = \sup C'$, then clearly $H_\gamma = \bigcup_{i \in I} H_\delta = \langle x_n, y_\beta : n \in \omega, \beta < \gamma \rangle_\ast$ and hence $\gamma \in C$.

It remains to show that $C$ is unbounded. Therefore assume that $C$ is bounded by $\delta^* < \kappa$, i.e. $\delta \leq \delta^*$ for all $\delta \in C$. We will show that there exists $\delta^* < \gamma < \kappa$ such that $H_\gamma = \langle x_n, y_\beta : n \in \omega, \beta < \gamma \rangle_\ast$, hence $\gamma \in C$ - a contradiction.

Let $\rho_1 = \delta^*$ and put

$$E_{\rho_1} = \langle x_n, y_\beta : n \in \omega, \beta < \rho_1 \rangle_\ast.$$  

Now choose $\rho_1 \leq \alpha_1 < \kappa$ such that $E_{\rho_1} \subseteq H_{\alpha_1}$. If $\alpha_1 \notin C$ choose $\alpha_1 \leq \rho_2 < \kappa$ such that $H_{\alpha_1} \subseteq E_{\rho_2} = \langle x_n, y_\beta : n \in \omega, \beta < \rho_2 \rangle_\ast$. Continuing this way we obtain a sequence of groups $E_{\rho_i}$ and $H_{\alpha_i}$ such that $E_{\rho_i} \subseteq H_{\alpha_i} \subseteq E_{\rho_{i+1}}$ for all $i \in \omega$. Let $\gamma = \sup \{ \rho_i : i \in \omega \} = \sup \{ \alpha_i : i \in \omega \}$. Then

$$H_\rho = \bigcup_{i \in \omega} H_{\alpha_i} = \bigcup_{i \in \omega} E_{\rho_i} = E_\gamma = \langle x_n, y_\beta : n \in \omega, \beta < \gamma \rangle_\ast$$

and hence $\gamma \in C$. This finishes the proof. $\blacksquare$

(Continuation of the proof of Theorem 5.1) Now let $\delta \in C$ such that $\delta > \aleph_1$. This is possible since $C$ is a cub by the previous Lemma 5.2. Note that $y_\delta \notin H_\delta$ but we have the following lemma.

**Lemma 5.3.** There exists $n^* \in \omega$ and a sequence of ordinals $\delta \leq \alpha_1 \leq \alpha_2 \cdots \leq \alpha_{n^*} < \kappa$ such that

$$\langle H_\delta + \mathbb{Z} y_\delta \rangle_\ast \subseteq \sum_{m \leq n^*} B_{\alpha_m} + H_\delta.$$
Proof. We induct on $\alpha \geq \delta$ to show the even stronger statement that for any $L \subseteq H_\alpha$, $L$ of finite rank, there exist $n^* \in \omega$ and $\delta \leq \alpha_1 \leq \alpha_2 \cdots \leq \alpha_{n^*} < \kappa$ such that

$$\langle H_\delta + L \rangle_s \subseteq \sum_{m \leq n^*} B_{\alpha_m} + H_\delta.$$ 

If $\alpha = \delta$, then we are done choosing $n^* = 1$ and $\alpha_1 = \alpha$.

If $\alpha > \delta$ is a limit ordinal, then $L \subseteq H_\alpha$ implies $L \subseteq H_\beta$ for some $\delta \leq \beta < \alpha$. Hence we are done by induction hypothesis.

If $\alpha = \beta + 1$, let $H_\alpha = H_\beta + B_\beta$ and let $L = \langle l_1, \ldots, l_k \rangle_s$. We can find representations

$$l_i = h_{\beta,i} + b_{\beta,i}$$

for all $1 \leq i \leq k$ where $h_{\beta,i} \in H_\beta$ and $b_{\beta,i} \in B_\beta$. We put

$$L_\beta = \langle h_{\beta,i}, (B_\beta \cap H_\beta) : 1 \leq i \leq k \rangle_s \subseteq H_\beta$$

which is a pure subgroup of finite rank of $H_\beta$. An easy calculation which is left to the reader shows that $L \subseteq L_\beta + B_\beta$.

Now induction hypothesis implies that there exist $n \in \omega$ and $\delta \leq \alpha_1 \leq \alpha_2 \cdots \leq \alpha_n$ such that

$$\langle H_\delta + L_\beta \rangle_s \subseteq \sum_{m \leq n} B_{\alpha_m} + H_\delta.$$ 

Another calculation shows that this implies

$$\langle H_\delta + L \rangle_s \subseteq \sum_{m \leq n} B_{\alpha_m} + B_\beta + H_\delta.$$ 

This finishes the proof. \hfill \blacksquare

(Continuation of the proof of Theorem 5.1) By Lemma 5.3 we can choose $n^* \in \omega$ and $\delta \leq \alpha_1 \leq \alpha_2 \cdots \leq \alpha_{n^*}$ such that

$$\langle H_\delta + \mathbb{Z}y_{\delta} \rangle_s \subseteq \sum_{m \leq n^*} B_{\alpha_m} + H_\delta.$$ 

For every $m \leq n^*$ we choose a finite set $W_m \subset \kappa$ and an integer $n_m \in \omega$ such that

$$B_{\alpha_m} \subseteq \left\langle \sum_{\gamma \in W_m} \mathbb{Z}y_{\gamma} + \sum_{i \leq n_m} x_i \right\rangle_s.$$ 

Collecting all these generators and letting $W = \bigcup_{m \leq n^*} W_m$ and $k = \max\{n_m : m \leq n^*\}$ we obtain

(5.3) $$\langle H_\delta + \mathbb{Z}y_{\delta} \rangle_s \subseteq B + H_\delta$$
where \( B = \left\langle \sum_{\gamma \in W} \mathbb{Z}y_{\gamma} + \sum_{i \leq k} x_{i} \right\rangle. \)

Now choose \( \beta \in \delta \backslash W \) and let \( n \geq k \) such that

\[
\begin{align*}
n &\in A_{\beta} \cap A_{\delta} \backslash \bigcup_{\gamma \in W, \gamma \neq \delta} A_{\gamma}.
\end{align*}
\]

Note that this choice is possible by Lemma 3.6. It is now straightforward to see that

\[
\begin{align*}
p_n^{-1}(y_{\delta} - y_{\beta}) &\in \langle H_{\delta} + \mathbb{Z}y_{\delta} \rangle^* \text{ but it is not an element of } B + H_{\delta} \text{ contradicting (5.3)}. This finishes the proof of Theorem 5.1 and therefore the proof of our Main Theorem 4.2. \hfill \Box
\end{align*}
\]
