ABSTRACT
Lightweight and high-performance materials are required for the application in automobile, aerospace, aircraft industries. The lightweight material can be obtained by developing composites by adding hard reinforcement particulates in the matrix of soft material. In this investigation, composites have been developed with varying weight% (6, 8, 10, and 12) of B\text{4}C in the matrix of Al7075. The mechanical properties and wear behavior of the composites were determined. Tensile strength and hardness were increased with an increase in weight % of the reinforcement. The wear rate was increasing with an increase in the sliding velocity at constant load. However, the increase in wear rate at velocities from 1.5 m/s to 2.5 m/s was decreasing with an increase in the weight% of the reinforcement.

KEYWORDS: Al7075 Alloy, Micro B\text{4}C, Stir Casting, Pin-On-Discotary Tribometer

INTRODUCTION
The Automobile, aircraft, aerospace applications required the use of lightweight and high performance of aluminum alloy-based metal matrix composites. Such requirements can only be met by the development of aluminum alloy metal matrix composites. The composites with reinforcement particles can be manufactured through various processes such as stir casting, squeezed casting, spray deposition, powder blending, and consolidation, in-situ processing. The aluminum alloy based composites reinforced with boron particles provide excellent strength, stiffness, hardness, wear resistance, and stability at high elevated temperature[1].

There are some challenges in the development of these composites and these are controlling microstructure and mechanical properties, cost of the product through optimum composition, method of manufacturing, and heat treatment[2]. From the literature review, it is revealed that most of the previous work was done to reinforce SiC and Al\text{2}O\text{3} particles in the matrix of the aluminum alloy.

Suresh et al have prepared Al7075/Al\text{2}O\text{3}/SiC hybrid metal matrix nanocomposites (HMMNCs) by the stir casting method. They examined the micro-hardness and wear behavior and found that wear properties like wear rate and friction coefficient of Al7075 were decreased with the increase in Al\text{2}O\text{3} and SiC powder and also with an increase in sliding velocity; micro-hardness value increased with an increasing weight percentage of the reinforcement[3].

In an investigation, Rajesh et al have formed Al7075-SiC/Al\text{2}O\text{3} composites with varied weight fraction of SiC/Al\text{2}O\text{3} by the stir casting. They observed the effect of heat treatment on mechanical characterization and wear behavior and found that the age-hardened Al7075/SiC+Al\text{2}O\text{3} composites showed excellent resistance to wear as compared to as-cast hybrid composite[4].
Bala Kumar et al developed Al6061 composite with reinforcement particulates of fly ash, graphite powder, and copper powder by the stir casting method. They investigated microstructure, wear, and friction characteristics and optimized the experimental results by Taguchi’s technique. They reported that the hardness of Al6061/fly ash/Cu/Gr composites was increased with the increasing weight percentage of the reinforcement. Both the frictional force and wear rate have decreased considerably with the weight percentage of reinforcement[5].

Daniel et al prepared Al5059/SiC/MoS2 hybrid metal matrix composites by stir casting method. They examined the microstructure and dry sliding wear and optimized the results by the ANOVA test. They reported that load and percentage of reinforcement are the most affecting factors for wear rate and 15% of SiC at 10 µm offered better wear resistance and friction coefficient in Aluminium Hybrid Metal Matrix Composites[6].

Radhika and Priyanka have fabricated Aluminium alloy reinforced with Zirconia (10 wt %) by using the stir casting technique. The adhesive wear test was done on the prepared specimen using a pin-on-disc tribometer and optimized by Taguchi’s method. They found that the wear rate has a direct variation with applied load and inverse variation with sliding distance and sliding velocity. They reported that applied load (73.83%) has a major impact on wear characterization[7].

Lara et al fabricated Al7075-Graphite composites by mechanical alloying and hot extrusion process. They examined the microstructural and wear behavior of the composites and found that this fabrication method produced notable grain refined; wear resistance of pure aluminum followed a linear relation with (grain size)^{-1/2}. Strength and hardness of composites increases as a direct function of milling time and Graphite content[8].

Rao et al prepared Al7075/TiC composites by the stir casting technique. They examined wear behavior of the composites and surface morphologies of the wear surfaces and concluded that with an increase in the percentage of the reinforcement, the wear resistance decreases. They further reported that wear appears to be decreased under the constant velocities at different sliding distances with increased weight % of the reinforcement whereas weight loss increases notably with an increase in applied load[9].

Ravi Kumar et al have fabricated Al7075/Al2O3/SiC hybrid composites by the stir casting method. They investigated the mechanical and wear behavior of the composites and obtained the optimum values for hardness for SiC: 9%, Heat Treatment Temperature: 180° C, and for wear rate SiC: 3%, Heat Treatment Temperature: 140° C[10].

Chandra et al developed Al7075 alloy composites reinforced with Albite particulate by the stir casting method. They found that hardness of Al7075-Albite particulate composite increases for the reinforcement up to 8wt.% and there was a decrease in hardness of the composite with the further addition of Albite particulates[11].

Radhika and Raghu manufactured LM 13 Aluminium/B4C metal matrix composites synthesized by means of liquid metallurgy technique. They investigated the wear behavior of the composites and concluded that the wear behavior increases with the increasing load and decreases with increasing velocity, sliding distance, and wt.% of reinforcement[12].

In the present work, Al7075- B4C composite with 6, 8, 10, and 12 wt % of B4C particles (average size 50 µm) were fabricated through the stir casting process. To determine the wear, wear behavior of Al7075-B4C composites was performed on a pin-on-disc rotary tribometer.
Wear Behavior of AL-7075 Composites Reinforced with Boron Carbide

Nomenclatures

- Al7075: Aluminium Alloy 7000 Series
- B₄C: Boron Carbide
- M0: Pure Al7075
- M6: Al7075+6 wt.% of B₄C
- M8: Al7075+8 wt.% of B₄C
- M10: Al7075+10 wt.% of B₄C
- M12: Al7075+12 wt.% of B₄C

Abbreviations

- ANOVA: Analysis of Variance
- HAMMCs: Hybrid Aluminium Metal Matrix Composites
- HMMNCs: Hybrid Metal Matrix Nano Composites

EXPERIMENTAL PROCEDURES

Selection of Materials

For the fabrication of the composites, Al7075 is considered as matrix and B₄C particles are considered as reinforcement as reported in our previous paper [13].

Fabrication

The composites under consideration are fabricated by using a stir casting technique. A vacuum furnace as shown in Fig. 1 is used for the casting of the composites [13].

![Figure 1: Vacuum Furnace.](image)

Mechanical Properties

The tensile strength, impact strength, and hardness tests are conducted on the Universal testing machine, Impact testing machine, and Brinell hardness tester respectively.
Density

The density of the composites is measured by using Archimedes’ principle. To validate the value of density, it is also calculated theoretically by the rule of mixture.

Sliding Wear Testing

For determining the behavior of wear of the composites, a sliding wear test is done on the advanced Rotary Tribometer manufactured by Ducom, Bangalore as shown in Fig. 2. The wear tests are conducted as per ASTM G99. Some of the specimens for wear test are prepared as per ASTM G99 and is shown in Fig. 3.

RESULTS AND DISCUSSION

Elemental Analysis

The elemental composition of matrix Al7075 and reinforcement B4C are shown in Table 1 and Table 2[13].

| Elements | Zn | Mg | Cu | Fe | Cr | Al |
|----------|----|----|----|----|----|----|
| % wt.    | 5.8| 2.4| 1.5| 0.2| 0.2| Balance |

Table 1: Chemical Analysis of Al7075 Alloy

| Elements | Purity | Boron | Carbide | O   | N   | Si  | Ni  |
|----------|--------|-------|---------|-----|-----|-----|-----|
| % wt.    | 99.9   | 77.2  | 22.3    | <0.1| <0.08| <0.1| <0.01 |

Table 1: Chemical Analysis of B4C Powder 50µm
Mechanical Properties

The tensile strength, impact strength, and hardness are shown in Table 3[13].

Table 2: Mechanical Properties of Al7075 Alloy and Its Composites

| Materials | Ultimate Tensile Strength (MPa) | Impact Strength (Joule) | Brinell Hardness Number (BHN) |
|-----------|---------------------------------|-------------------------|-------------------------------|
| M0        | 129.776                         | 64.5                    | 85.1                          |
| M6        | 196.325                         | 42.0                    | 109.4                         |
| M8        | 206.235                         | 35.5                    | 112.6                         |
| M10       | 217.365                         | 27.5                    | 118.8                         |
| M12       | 232.781                         | 25.0                    | 125.2                         |

Density

The density of the fabricated composites with different volume fractions of reinforcements is shown in Fig. 4. From Fig. 4, it is observed that with an increase in the volume fraction of reinforcement the density of composite decreases. The value of experimental density is lower than that of the theoretical value of composite except for 0% reinforcement i.e. pure aluminum alloy.

Wear Test

The sliding wear test of the fabricated composites was performed at sliding velocities 1.5 m/s, 2.5 m/s, and 3.5 m/s for a total sliding distance of 2 km. At each sliding velocity, the load was 10 N, 15 N, and 20 N for each experiment. During the wear test at 10 N, 15 N and 20 N load, the mass loss after 2 km sliding distance was measured. The mass loss at 10 N, 15 N and 20 N are shown in Fig. 5, Fig. 6 and Fig. 7 respectively. From Fig. 5, Fig. 6 and Fig. 7, it is observed that the mass loss increases with an increase in sliding velocity. It is also observed that there is a decrease in wear that is mass loss with an increase in the volume fraction of the reinforcement (B₄C).
Figure 5: Mass Loss of Pure Al7075 and Its Composites with Load 10 N.

Figure 6: Mass Loss of Pure Al7075 and Its Composites with Load 15 N.

Figure 7: Mass Loss of Pure Al7075 and Its Composites with Load 20 N.

Wear Rate

The wear rate of the fabricated composites is shown in Fig. 9, Fig. 10 and Fig. 11 at velocities 1.5 m/s, 2.5 m/s and 3.5 m/s respectively.
Effect of Load

From the result, it is observed that the load is affecting the wear behavior of the developed composites. From Fig. 9, Fig. 10, and Fig. 11 it is found that the mass loss is increasing with increasing the load. This finding is in agreement with that reported by Radhika and Priyanka [7] and Rao et al[9].
Effect of Velocity

From the result of the wear rate, it is observed that there is variation in wear rate with the varying velocity of sliding. From Fig. 6, Fig. 7, and Fig. 8 it is observed that there is an increase in mass loss with increasing the velocity which is similar to the finding of Suresh et al. it is also observed that there is a decrease in mass loss with increase in the weight percent of the reinforcement at a given sliding velocity.

Effect of Strength and Hardness

The ultimate tensile strength of the composite was found to be highest with 12% B₄C. so it can be said that the wear rate is affected by the strength of the material. With an increase in strength, there is an increase in wear resistance. It is also found that wear behavior is also depending on the hardness of the material. With increasing hardness, there is an increase in wear resistance of the composites and these are similar to the finding reported by Lara et al[8].

CONCLUSIONS

From the investigation of wear behavior of Al7075/B₄C composites, the following findings are observed:

- Tensile strength and hardness increase with an increase in weight % of the reinforcement.
- Experimental density is lower than the theoretical one.
- The wear rate is decreasing with an increase in weight% of the reinforcement (B₄C) at a constant velocity.
- The wear rate is increasing with the increase in load at a constant velocity.
- The wear rate is increasing with an increase in the sliding velocity at constant load. However, the increase in wear rate at velocities from 1.5 m/s to 2.5 m/s is decreasing with an increase in the weight% of the reinforcement.

ACKNOWLEDGMENTS

The authors wish to thank the Department of Mechanical Engineering, KNIT, Sultanpur, U. P., India for providing facilities and necessary support in conducting experiments.

The authors are thankful for the World Bank Technical Education Quality Improvement Programme Phase-III (WB TEQIP-III) Grant/Scheme No. 2038 Project of KNIT, Sultanpur also for financial assistance.

CONFLICTS OF INTEREST

The authors declare no conflicts of interest.
