Ageing of a gas/liquid interface elongated by standing waves

Laboratoire des Ecoulements Géophysiques et Industriels, BP 53, Grenoble Cedex 9, France

This paper aims at modelling the interfacial ageing induced by the sudden arising of standing capillary waves at a contaminated air/water interface. Here is thus considered a brimful cylindrical reactor filled with a water bath in which surfactants are solubilized. The cylindrical capillary waves at the air/water free surface are responsible for further production of interfacial area. The surface diffusion being supposed instantaneous, Marangoni effect does not play any damping role. The thermodynamical equilibrium achieved when the interface is at rest, is considered as initial condition. The time-dependence of the surface concentration in surfactants, $C(t)$, and of the bulk concentration in surfactants at the vicinity of the interface, $C_{b}(t)$, is analytically modelled taking into account the serial coupling between bulk diffusion and sorption phenomena. As recommended by Yariv and Frankel [E. Yariv, J. Frankel, Phys. Rev. Lett. 89 (2002) 26], none assumption on the source of the ageing is formulated in the transient regime under consideration.

Keywords: Gas/Liquid interface; Surfactants; Capillary waves

1. Introduction

This paper is a contribution to a research devoted to the development of a new bio-chip based on a gas/liquid interface covered by a functionalized monolayer [2]. After the adsorption of target biological molecules (proteins, DNA strands, etc.), initially solubilised within the underlying liquid phase, it is found that a diagnostic based on the instantaneous, Marangoni effect does not play any damping role. The thermodynamical equilibrium achieved when the interface is at rest, is considered as initial condition. The time-dependence of the surface concentration in surfactants, $C(t)$, and of the bulk concentration in surfactants at the vicinity of the interface, $C_{b}(t)$, is analytically modelled taking into account the serial coupling between bulk diffusion and sorption phenomena. As recommended by Yariv and Frankel [E. Yariv, J. Frankel, Phys. Rev. Lett. 89 (2002) 26], none assumption on the source of the ageing is formulated in the transient regime under consideration.

2. Mathematical model

2.1. Conservation equations and closure laws

When the interface is populated by SCCW, the elevation $\zeta$ of the wavy surface, the vertical velocity $v_{z}$ and the radial velocity $v_{r}$ at the vicinity of the interface can be approximated by

$$\begin{align*}
\zeta(r,t) & = \zeta_{0}J_{0}(kr) \sin(\omega t), \\
v_{z}|_{z=0} & = \zeta_{0}J_{0}(kr) \cos(\omega t), \\
v_{r}|_{z=0} & = \zeta_{0}J_{1}(kr) \cos(\omega t),
\end{align*}$$

(1)

where $J_{0}$ and $J_{1}$ are the Bessel functions of the zeroth and the first order, respectively. The symbols $r$, $t$, $\zeta_{0}$, $\omega$, denote, respectively, the radial coordinate, the time, the wave number, the surface elevation along the reactor axis, the amplitude of the radial displacement of a surface particle and finally, the wave frequency (see also Fig. 1). The notation $X|_{z=0}$ is referred to...
to as the value of the bulk quantity $X$ at the vicinity of the interface ($\zeta = 0$).

Making use of the Gibbs hypothesis\(^1\) and considering the gas phase as neutral (no adsorption from/to air and no diffusion within air), the transport equations for the bulk and surface concentrations in surfactants, $C(t, r, z)$ and $\Gamma(t, r)$, simplify, respectively, to

$$\frac{\partial C}{\partial t} + \vec{v} \cdot \nabla C = - \nabla \cdot \vec{J}, \quad \frac{d\Gamma}{dt} + \Gamma \nabla \cdot \vec{v} + \Gamma (\nabla \cdot \vec{\xi}) + \nabla \cdot \vec{J}_\sigma = \frac{\partial}{\partial t} \Gamma.$$

Here, use is made of the gradient operator, $\nabla$, the divergence operator defined (in the liquid bulk) at the vicinity of the interface ($\zeta = 0$).\

The symbols $\vec{v}$, $D$, $\vec{\xi}$, $\vec{J}$, $\vec{J}_\sigma$ and $\vec{\xi}$ refer to as the velocity and the chemical diffusivity in the bulk, the surface velocity, the chemical flux in the bulk and the chemical flux in the vicinity of the interface, the intrinsically 2D surface chemical flux and, finally, the unit vector normal to the interface, directed from the liquid to the gas phases. Assuming the liquid phase is dilute enough, Fick’s law is the closure law which allows us to write explicitly the chemical flux due to sorption energy barrier:

$$\vec{J}_\sigma \cdot \vec{\xi} = k_a C \left( 1 - \frac{\Gamma}{\Gamma_\infty} \right) - k_d \frac{\Gamma}{\Gamma_\infty}. \quad (5)$$

The symbols $k_a$, $k_d$, $C_0$, and $\Gamma_\infty$ denote the adsorption and desorption coefficients, the bulk concentration at the vicinity of the interface and the maximum packing surface concentration. As a consequence, the mathematical model here-considered writes as

$$\frac{\partial C}{\partial t} + \vec{v} \cdot \nabla C = D \Delta C,$$

where the symbol $\Delta$ denotes the Laplacian operator.

2.2. Conservation equation in the wavy interface

The mathematical model has been written with intrinsic notations. Tensorial analysis has to be performed in order to write explicitly the surface concentration equation within the wavy interface. After calculation of the metric tensors and the Christoffel symbols \[^4\], it is possible to write explicitly the transport equation for the surfactant in a cylindrical coordinates system (Fig. 2).

The 3D metric tensor quite well-known when connecting Cartesian to cylindrical coordinates systems is derived as

$$g^{\theta \theta} = \begin{bmatrix} f^{-1} & 0 \\ 0 & \frac{1}{\rho} \end{bmatrix}$$

and the only non-vanishing Christoffel symbols write as

$$\begin{align*}
\frac{\partial}{\partial \rho} & = 1, \\
\frac{\partial}{\partial \theta} & = \rho, \\
\frac{\partial}{\partial \varphi} & = r.
\end{align*}$$

\[^1\] The interface is handled as a two-dimensional medium.

\[^4\] The Christoffel symbols recently demonstrated that sorption phenomena must be taken into account when evolution of $\Gamma$ at small times ($t \ll 1$) is of interest. This finding results from the fact that sorption and diffusion phenomena are two serial chemical fluxes. The former set of equations has to be completed by the Langmuir law which is assumed to describe conveniently the chemical flux due to sorption energy barrier:
where the symbol $f$ is defined as

$$f = 1 + \left( \frac{\partial \Gamma}{\partial r} \right)^{-1}.$$

From these calculations, the covariant derivatives of the contravariant quantities involved in (6) can be easily derived [5]; the subsequent mathematical formulation writes explicitly:

$$\frac{d\Gamma}{dt} + \Gamma \left( \frac{\partial r}{\partial r} \frac{d\Gamma}{dr} \right) f^{-1} = - \frac{\partial C}{\partial z} |_{z=0}.$$

2.3. Non-dimensional mathematical formulation

Non-dimensional numbers can be made evident from a careful analysis of the characteristic scales. To make non-dimensional the coordinates $r$ and $z$, the length scales are found to be $k^{-1}$ and $\zeta_0$. The scales for the bulk and surface concentrations are found when the interface remains at rest, in thermodynamical equilibrium with the bulk: $C_\infty$ and $\Gamma_e$ are calculated from the Langmuir law according to

$$\Gamma_e = \frac{\Gamma_\infty C_\infty}{C_\infty + k_d/k_a}.$$

A natural scale for the velocity component $v_z$ is the quantity $\zeta_0 \omega$. Subsequently, taking into account the mass conservation equation, the scale for $v_r$ is found to be $k^{-1} \omega$.

There remains now the question of finding a relevant time scale. The relevant time scales for (i) the diffusion in the bulk, (ii) the diffusion-limited surface ageing, (iii) the sorption-limited surface ageing, (iv) the surface diffusion and finally, (v) the dynamical deformation of the interface, can be deduced from the respective balances:

$$\frac{\partial C}{\partial t} \sim D \frac{\partial^2 C}{\partial z^2} \Rightarrow t_d \sim \frac{\zeta_0^2}{D}.$$

$$\frac{d\Gamma}{dt} \sim - D \frac{\partial C}{\partial t} \Rightarrow t_{ad} \sim \frac{\Gamma_\infty C_\infty}{C_\infty + k_d/k_a} D.$$

$$\frac{d\Gamma}{dt} \sim k_a C_s \left( 1 - \frac{\Gamma}{\Gamma_\infty} \right) \Rightarrow t_{as} \sim k_a C_s C_\infty + k_d.$$

$$\frac{d\Gamma}{dt} \sim D \frac{\partial^2 \Gamma}{\partial z^2} \Rightarrow t_{ad} \sim \frac{k^{-2}}{D_0}.$$

Fig. 2. Coordinates systems.
\[ \frac{\partial C}{\partial t} \sim v_{\text{inj}} \Rightarrow t_\omega \sim \sigma \omega^{-1}. \]  
(11)

The evolution of the concentrations within the bulk and the interface and the Poincaré parameter which is nothing but the ratio:

\[ \frac{N}{N_\sigma} \]

and where the numbers:

\[ C_\omega \]

are defined as ratios of times scales:

\[ N_\text{adj} f^{-1/2} \left( \frac{2 \frac{\partial C}{\partial z} \bigg|_{z=0}}{\frac{\partial C}{\partial z} \bigg|_{z=0}} \right) \]

with the initial conditions:

\[ C(t=0, r, z) = 1, \quad \Gamma(t=0) = C(t=0, z) = 1, \]

\[ \text{where the non-dimensional numbers } N_{\sigma, N_{\text{adj}}, Pe, N_{\text{adj}}, N_{\text{m}}} \text{ are defined as ratios of times scales:} \]

\[ N_{\sigma, N_{\text{adj}}, Pe, N_{\text{adj}}, N_{\text{m}}} = \frac{t_{\sigma, N_{\text{adj}}, Pe, N_{\text{adj}}, N_{\text{m}}}}{t_\omega} = \frac{k \eta C_{\omega}^2}{k_\eta C_{\omega}}, \quad \frac{t_{\sigma, N_{\text{adj}}, Pe, N_{\text{adj}}, N_{\text{m}}}}{t_\omega} = \frac{t_{\omega}}{t_{\omega}} = \frac{t_{\omega}}{t_{\omega}}, \quad \frac{t_{\sigma, N_{\text{adj}}, Pe, N_{\text{adj}}, N_{\text{m}}}}{t_\omega} = \frac{t_{\omega}}{t_{\omega}} = \frac{t_{\omega}}{t_{\omega}}, \quad \frac{t_{\sigma, N_{\text{adj}}, Pe, N_{\text{adj}}, N_{\text{m}}}}{t_\omega} = \frac{t_{\omega}}{t_{\omega}} = \frac{t_{\omega}}{t_{\omega}}, \]

and where the numbers:

\[ N_\sigma = \frac{a}{\epsilon_\infty + a} = 1 - \frac{\Gamma_\infty}{\Gamma_\infty} \]

and

\[ \epsilon = \kappa_{\text{Eo}} \]

stand, respectively, as the gap to cross before saturating the interface and the Poincaré parameter which is nothing but the typical slope of the standing cylindrical ripples.

2.4. Instantaneous surface diffusion

To simplify more the problem, we consider the asymptotic situation for which intrinsic surface diffusion is instantaneous (\( N_{\text{adj}} \ll N_{\text{adj}} \)) and the waves-driven radial \( \Gamma \) gradients vanish. This approach is consistent with the fact that wave damping due to Marangoni effect is supposed to be negligible. Then, an average process allows us to make the problem mono-dimensional: the concentrations \( C = C(t, z) \) and \( \Gamma = \Gamma(t, z) \) are considered as uniform over horizontal cross-sections and an excitation term \( E(t) \) can be defined as the radial mean value of the dilational term, proportional to \( N_{\text{adj}} \) in (12). Because of the Dirichlet boundary conditions for the surface velocity \( (v_{z, \text{inj}}(r = 0) = v_{z, \text{inj}}(r = R) = 0 \) where \( R \) is the dimensionless radius of the outer pinned), the radial average of the \( C(t) \)-order term is null and the excitation \( E \) appears as a \( O(\epsilon^3) \)-order term:

\[ E = O(\epsilon^3) \]

3. Perturbation method

To put forward an analytic solution despite the strong coupling between the differential Eqs. (12) and (14), it is convenient to focus on small amplitude SCCW. From a practical viewpoint, this restriction is consistent with the requirement to avoid any damage to the structure of the adsorption layer at the air/water interface. In particular, Faraday waves are not considered here. As a consequence, one seeks the solution of system (12)–(15) as a (regular) perturbation series with \( \eta = \epsilon^3 \) as the small parameter:

\[ \Gamma = \Gamma_0 + \eta \Gamma_1 + \mathcal{O}(\epsilon^3), \quad C = C_0 + \epsilon C_1 + \mathcal{O}(\epsilon^3), \quad E = \eta E_1 + \mathcal{O}(\epsilon^3), \]

\[ \text{where } E_1 \text{ can be expressed from (16):} \]

\[ E_1(t) = \frac{t_{\omega}}{t_{\omega}} \int_0^1 \frac{f(t)}{R^2} \, \mathrm{d}r \]

(19)

3.1. Model at \( O(1) \)

By making use of (17) to transform the mathematical formulation (12)–(14), it is possible to derive the mathematical model at \( O(1) \)-order:

\[ \frac{\partial C_0}{\partial t} = C_0 \frac{t_{\omega}}{t_{\omega}} \left[ 1 - (1 - N_\sigma) \Gamma_0(t) \right] + N_\sigma \frac{C_0}{\partial z} \frac{\partial C_0}{\partial z} \]

(18)

\[ \frac{t_{\omega}}{t_{\omega}} \left[ 1 - (1 - N_\sigma) \Gamma_0(t) \right] = -N_{\text{adj}} \frac{C_0}{\partial z} \frac{\partial C_0}{\partial z} \]

(15)
Taking account of the initial conditions (15), the solution at zeroth-order is directly deduced from the thermodynamical equilibrium:

\[ C_0 = 1, \quad \Gamma_0 = 1. \]  

(20)

This result is consistent with the fact that when \( \eta \equiv 0 \), the interface remains at rest.

### 3.2. Model at \( C(\eta) \)

To get the time-dependence of the concentrations, the mathematical model at \( C(\eta) \)-order has to be drawn up

\[
\frac{\partial C_1}{\partial t} + \Gamma_1 = -N_\sigma C_1_{|z=0} - E_1,
\]

(21)

\[
N_\sigma \frac{\partial C_1}{\partial z} = \frac{\partial^2 C_1}{\partial z^2},
\]

(22)

\[
N_\sigma C_1_{|z=0} - \Gamma_1 = -N_\sigma \frac{\partial C_1}{\partial C} |_{z=0},
\]

(23)

with the following initial conditions:

\[
C_1(t = 0, r, z) = 0, \quad \Gamma_1(t = 0, r, z) = 0.
\]

(24)

When the non-dimensional number \( N_\sigma \) tends to zero, Eq. (23) indicates that sorption kinetics is mainly controlled by the level of the surface concentration \( \Gamma_1 \). After a brief inspection to the former mathematical formulation, it is worth emphasizing that the feedback coupling due to the convective motion inside the bulk, originated from the ripples at the interface, is not taken into account at \( C(\eta) \)-order. Nevertheless, the dilatational term \( \Gamma_1 \) in (21), proportional to \( N_\sigma \) number, shows how the dynamical surface deformation is able to induce variations on the surface concentration.

### 4. The \( C(\eta) \)-solution

As for the Ward and Tordai equation, it is relevant to seek the solution of our initial-value problem making use of the Laplace transform. If \( \tilde{X} \) in (15), the Laplace transform of the unknown \( X(t, r, z) \), from (20) and (24), one shows that the \( C(\eta) \)-model in the Laplace space writes:

\[ x \tilde{\Gamma}_1 + \tilde{\Gamma}_1 = N_\sigma \tilde{C}_1_{|z=0} - \tilde{E}_1. \]

(25)

\[ N_\sigma \frac{\partial \tilde{C}_1}{\partial z} = \frac{\partial^2 \tilde{C}_1}{\partial z^2} = 0, \]

(26)

\[ N_\sigma \tilde{C}_1_{|z=0} + N_\sigma \frac{\partial \tilde{C}_1}{\partial z} |_{z=0} = \tilde{\Gamma}_1, \]

(27)

Introducing the non-dimensional number \( m \):

\[ m = \frac{N_\sigma}{N_\sigma \sqrt{N_\sigma}}, \]

(28)

which compares the sorption flux limited by the \( \Gamma_1 \) level to the diffusion-limited fluxes, the unknowns of interest are derived as

\[ \tilde{C}_1_{|z=0} = -\frac{m}{N_\sigma \sqrt{\sqrt{t} + m \sqrt{\sqrt{t} + 1}}}, \]

\[ \tilde{\Gamma}_1 = \frac{1}{t + m \sqrt{\sqrt{t} + 1}}, \]

(29)

(30)

Defining \( n = \sqrt{m^2 - 4} \), it can be demonstrated if \( n^2 \neq 0 \):

- that the time-dependent bulk concentration at the vicinity of the interface writes:

\[ C_1_{|z=0}(t) = -\frac{4m}{nN_\sigma \sqrt{t}} \int_0^t E_1(t - \tau) \times \int_0^\infty e^{-\sqrt{\sqrt{t} + u} \sqrt{\sqrt{t} + 1}} du \, d\tau, \]

\[ \Gamma_1(t) = \frac{1}{t + m \sqrt{\sqrt{t} + 1}}, \]

\[ x \tilde{\Gamma}_1 + \tilde{\Gamma}_1 = N_\sigma \tilde{C}_1_{|z=0} - \tilde{E}_1. \]

(31)

(32)

If \( n^2 = 0 \), the expressions for \( C_1_{|z=0} \) and \( \Gamma_1 \) simplify to

\[ C_1_{|z=0}(t) = -\frac{4m}{N_\sigma \sqrt{\sqrt{t} + 1}} \int_0^t \sqrt{\sqrt{t} + u} E_1(t - \tau) \times \int_0^\infty e^{-\sqrt{\sqrt{t} + u} \sqrt{\sqrt{t} + 1}} du \, d\tau, \]

\[ \Gamma_1(t) = \frac{1}{\sqrt{\sqrt{t} + 1}}, \]

\[ x \tilde{\Gamma}_1 + \tilde{\Gamma}_1 = N_\sigma \tilde{C}_1_{|z=0} - \tilde{E}_1. \]

(33)

(34)

Replacing \( E_1 \) by (18), when \( t \to \infty \), expressions (31)–(34) can be also considered as the imaginary part of Laplace transforms already found in (29) and (30). Consequently, the asymptotic expression of the concentrations \( C_1_{|z=0} \) and \( \Gamma_1 \) write:

\[ C_1_{|z=0}(t) = -\frac{m JN_\sigma^{\frac{n}{2}} e^{2\sqrt{\sqrt{t} + 1}}}{4 N_\sigma \sqrt{4N_\sigma^{2} + 2N_\sigma^{2} \sqrt{2N_\sigma^{2} + 1}}} \]

(35)

\[ \Gamma_1(t) = \frac{1}{N_\sigma \sqrt{4N_\sigma^{2} + 2N_\sigma^{2} \sqrt{2N_\sigma^{2} + 1}}} \]

(36)

### 5. Time evolutions and discussion

It is now relevant to assess the influence of each non-dimensional number onto the time evolution of the concentrations \( \Gamma_1 \) and \( C_1_{|z=0} \).
The number \( m \) controls the small frequency–kinetics evolution of \( \Gamma_1 \) during the transient regime i.e. the transient delay the heterogeneous system needs to reach the new thermodynamical equilibrium associated to the steady (wavy) regime. Typically, when \( m \) increases, the kinetics of the transient regime becomes slower (see Figs. 3 and 4).

The non-dimensional number \( N_{as} \) characterises the (high frequency) oscillating behaviour of \( \Gamma_1 \). A look at the evolution of \( C_1|_{z=0} \) tells us that the amplitude of the oscillations decreases for high values of \( N_{as} \). This is consistent with the fact that, all things being equal, the quickest the oscillating surface deformation is, the slowest the response of the bulk concentration \( C_1|_{z=0} \) to any change of interfacial area is (Fig. 5). The time evolution of the surface concentration is close to the one of a non-soluble surfactant.

It can be relevant to distinguish the diffusion-limited ageing from the sorption-limited ageing in order to classify surfactants. The Ward and Tordai equation is the well-known expression which models the diffusion-limited ageing of a freshly formed bubble interface at the tip of a tube. Here things are different because first, our interface is periodically perturbed around a pre-existing situation of thermodynamical equilibrium and second, the geometry of the surface deformation originates from standing waves. Relations (32) and (33) have been demonstrated in a general manner. It is now worth regarding how they can be simplified when diffusion/sorption-limited ageings prevail.

### 5.1. Sorption-limited ageing

If diffusion kinetics within the bulk is supposed instantaneous, one can consider \( N_{ad} \rightarrow 0 \). As a consequence, bulk concentration remains uniform: \( C_1|_{z=0} = C_1(t, z) \equiv 0 \). The corresponding mathematical model simplifies drastically to a linear first-order differential equation whose solution writes as

\[
\Gamma_1(t) = -e^{-t} \int_0^t E_1(\tau) e^{\tau} d\tau. \tag{37}
\]

### 5.2. Diffusion-limited ageing

The time scale \( t_{ad} \) is no longer relevant and \( t_{ad} \) is now retained to derive a relevant non-dimensional mathematical model. For the classical hypothesis of diffusion-limited ageing, sorption phenomena are supposed to be instantaneous: \( N_{as} \rightarrow 0 \). The final mathematical model for the diffusion-limited regime writes as

\[
\frac{\partial \Gamma_1}{\partial t} = -\frac{\partial C_1}{\partial z}|_{z=0} - E_1, \tag{38}
\]

\[
N_{ad} \frac{\partial C_1}{\partial t} = \frac{\partial^2 C_1}{\partial z^2}, \tag{39}
\]

\[
N_{ad} \Gamma_1|_{z=0} = \Gamma_1, \tag{40}
\]

where the non-dimensional number, \( N_{ad} \), is defined as the ratio between the two diffusion kinetics:

\[
N_{ad} = \frac{t_{ad}}{t_{as}} = \frac{C_\infty s_0}{T_\infty}. \tag{41}
\]

Here again, by making use of the Laplace transform, it is possible to derive the two concentrations of interest as follows:

\[
C_1|_{z=0}(t) = -\frac{1}{N_{as}} \int_0^t E(t - \tau) e^{\tau} \text{erfc}(\sqrt{q} \sqrt{\tau} \sigma) d\tau, \tag{42}
\]
\begin{equation}
\Gamma_1(t) = -\int_0^1 E(t - \tau)e^{\frac{1}{2}\tau} \text{erfc}(q\sqrt{\tau})d\tau,
\end{equation}

with the new non-dimensional number, \( m_{ad} \), defined as the ratio:
\begin{equation}
q = \sqrt{\frac{N_{ad}}{N_0}}
\end{equation}

By comparing the predictions of the diffusion-limited and generic models, one checks easily that agreement is achieved only when \( N_{ad} \to 0 \). As soon as this asymptotic criteria is no longer respected, a disagreement appears at the very beginning of the ageing as \( t \to 0 \). In agreement with Yariv and Frankel [1], at small times, sorption is shown to become the limiting phenomenon. A second limitation of the diffusion-limited model arises when the frequency of the oscillating surface deformation becomes large enough compared to the sorption kinetics (\( t_m \sim t_{as} \) or \( t_m < t_{as} \)); typically, when \( t_{as} \) is too small, the adsorption–desorption equilibrium is found no longer valid.
