CHARACTERIZATION OF THE ANDERSON METAL-INSULATOR TRANSITION FOR NON ERGODIC OPERATORS AND APPLICATION

CONSTANZA ROJAS-MOLINA

ABSTRACT. We study the Anderson metal-insulator transition for non ergodic random Schrödinger operators in both annealed and quenched regimes, based on a dynamical approach of localization, improving known results for ergodic operators into this more general setting. In the procedure, we reformulate the Bootstrap Multiscale Analysis of Germinet and Klein to fit the non ergodic setting. We obtain uniform Wegner Estimates needed to perform this adapted Multiscale Analysis in the case of Delone-Anderson type potentials, that is, Anderson potentials modeling aperiodic solids, where the impurities lie on a Delone set rather than a lattice, yielding a break of ergodicity. As an application we study the Landau operator with a Delone-Anderson potential and show the existence of a mobility edge between regions of dynamical localization and dynamical delocalization.

1. INTRODUCTION

Under the effect of a random perturbation, the spectrum of an ergodic Schrödinger operator is expected to undergo a transition where we can identify two distinct regimes: the insulator region, characterized by localized states and the metallic...
region, characterized by extended states. The passage from one to the other under a certain disorder regime is known as the Anderson metal-insulator transition. Although a precise spectral description of this phenomena is still out of reach, this transition is better characterized in terms of its dynamical properties. Germinet and Klein tackled this problem in [GK3] by introducing a local transport exponent $\beta(E)$ to measure the spreading of a wave packet initially localized in space and in energy evolving under the effect of the random operator. This provides a proper dynamical characterization of the metal-insulator transition, and the mobility edge, i.e. the energy where the transition occurs, is shown to be a discontinuity point of $\beta(E)$.

Since ergodicity is a basic feature in the theory of random Schrödinger operators, Germinet and Klein’s work was done in that framework. However, more real models may lack this fundamental property, examples of this kind of systems are Schrödinger operators with Anderson-type potentials where the random variables are not i.i.d. or where impurities are located in aperiodic discrete sets. The first case (sparse models, decaying randomness, surfacic potentials) has been studied in [BKS], [BdMSS], [KV], [S], while the second case (Delone-Anderson type potentials) has been treated in [BdMNSS]. In the deterministic case, Delone operators have been studied with a dynamical systems approach in [KLS] and [MR].

We aim to study the Anderson metal-insulator characterization in a general non ergodic setting, with minimal requirements on the model to fit the dynamical characterization of localization/delocalization using the local transport exponent $\beta(E)$, extending the results of [GK3] to the non ergodic models mentioned above. The main tool in the study of the transport transition is the Multiscale Analysis (MSA), initially developed by Fröhlich and Spencer [FrS], it has been improved over the last three decades to its strongest version so far, the Bootstrap MSA by Germinet and Klein [GK1]. The Bootstrap MSA yields among other features strong dynamical localization in the Hilbert-Schmidt norm, and so it can be used to characterize the set of energies where the transport exponent is zero, that is associated to dynamically localized states [GK3], but since it was originally developed in the frame of ergodic operators it is not suitable when there is lack of ergodicity, so we adapt it to our model. What completes the dynamical characterization is the fact that, in the ergodic case, slow transport in average over the randomness, the so-called annealed regime, implies dynamical localization. This holds in our new setting and, moreover, this can be improved and it can be shown that it is enough to have slow transport with a good probability, that is, in a quenched regime, to obtain dynamical localization, so in both quenched and annealed regimes the metal-insulator transition can be characterized in an analogous way. There are examples related to the Parabolic Anderson model where the behavior of the solution in both regimes differ from each other and this can depend on the density of the random variables [GaKo].

We obtain uniform Wegner estimates needed for the adapted version of the Bootstrap MSA for both the Laplacian and the Landau operator with Delone-Anderson potentials, that is, Anderson potentials where the impurities are placed in an a priori aperiodic set, called a Delone set. It is known that a way to obtain Wegner estimate is to “lift” the spectrum by considering the random Hamiltonian as a negative perturbation of a periodic Hamiltonian whose spectrum starts above a certain energy above the bottom of the spectrum of the original free Hamiltonian (called
fluctuation boundary). In this way the Wegner estimate is obtained “outside” the spectrum of the periodic operator, as in [BdML]. We stress the fact that this approach is not convenient in our case since we have no information on where the fluctuation boundary lies. On the other hand, [CHK] and [CHK2] take a different approach by using a unique continuation property to prove Wegner estimates without a covering condition on the single-site potential, and not using fluctuation boundaries. The results in [CHK] rely strongly on the periodicity of the lattice and the use of Floquet theory, which, again, cannot be used in our model since our set of impurities is aperiodic. However, this was improved in [CHKR] to obtain a positivity estimate for the Landau Hamiltonian that does not rely on Floquet theory, which makes it convenient for our setting. In the case of the free Laplacian (see [G]) we use a spatial averaging method as in [GKH], [BoK] to prove the required positivity estimate, thus bypassing the use of Floquet theory. As a result we obtain a uniform Wegner estimate at the bottom of the spectrum in an interval whose length depends only on the Delone set parameters and not in the disorder parameter $\lambda$. We also obtain Wegner estimates in the case where the background Hamiltonian is either periodic or the Landau operator. For the latter, and as an application of the main results, we can show the existence of a metal-insulator transition, as expected from the ergodic case [GKS]. Since the lattice is a particular case of a Delone set, these results imply in particular those of the ergodic setting. By the lack of ergodicity we cannot make use of the Integrated Density of States to prove the existence of a non random spectrum for $H_\omega$, nor use the characterization of the spectrum in terms of the spectra of periodic operators as done in [GKS2] to locate the spectrum in the Landau band. Therefore, to show our results are not empty we need to prove that we can almost surely find spectrum near the band edges, which is done adapting an argument in [CH, Appendix B] in a not necessarily perturbative regime of the disorder parameter $\lambda$. We stress that we consider a general Delone set and do not assume any geometric property, like repetitivity or finite local complexity. These features, however, might be needed for further results, for example, related to the Integrated Density of States (see [MR], [LS3], [LV]).

The present note is organized as follows: in Section 2 we adapt the Bootstrap MSA to fit our new setting. In Section 3 we prove the results on the dynamics in both annealed and quenched regimes. In Section 4 we prove uniform Wegner estimates for Delone-Anderson random Schrödinger operators. In Section 5, in the lines of [GKS] we proof the existence of a metal-insulator transition for a Landau Hamiltonian with a Delone-Anderson potential and the existence of almost sure spectrum near the band edges, that has non empty intersection with the localization region.

2. Main results

For $x \in \mathbb{R}^d$ we denote by $\|x\|$ the usual euclidean norm while the supremum norm is defined as $|x|_\infty = \max_{1 \leq i \leq d} |x_i|$, where $|\cdot|$ stands for absolute value.

Given $x \in \mathbb{R}^d$ and $L > 0$ we denote by $B(x, L)$ the ball of center $x$ and radius $L$ in the $\|\cdot\|_\infty$-norm, while the set

$$\Lambda_L(x) = \left\{ y \in \mathbb{R}^d : |y - x|_\infty < \frac{L}{2} \right\}$$
defines the cube of side $L$ centered at $x$, also denoted as $\Lambda_{x,L}$. We denote the volume of a Borel set $\Lambda \subset \mathbb{R}^d$ with respect to the Lebesgue measure as $|\Lambda| = \int_{\mathbb{R}^d} \chi_\Lambda(x)\,dx$, where $\chi_\Lambda$ is the characteristic function of the set $\Lambda$. We will often write $\chi_{x,L}$ for $\chi_{\Lambda_{x,L}}(x)$ and denote by $\|f\|_{x,L}$ or $\|f\|_{\Lambda_{x,L}}$ the norm of $f$ in $L^2(\Lambda_{x,L})$.

We denote by $C^\infty_c(\Lambda)$ the vector space of real-valued infinitely differentiable functions with compact support contained in $\Lambda$, with $C^\infty_{c,+}(\Lambda)$ being the subclass of nonnegative functions.

We denote by $\mathcal{B}(\mathcal{H})$ the Banach space of bounded linear operators on the Hilbert space $\mathcal{H}$. For a closed, densely defined operator $A$ with adjoint $A^*$, we denote its domain by $\mathcal{D}(A) \subset L^2(\Lambda)$ and by $\|A\| = \sup\{\|A\phi\| : \|\phi\| = 1\}$ its (uniform) norm if bounded. We define its absolute value by $|A| = \sqrt{A^*A}$ and, for $p > 1$, we define its (Schatten) $p$-norm in the Banach space $\mathcal{J}_p(L^2(\Lambda))$ as $\|A\|_p = (\text{tr}(|A|^p))^{1/p}$.

In particular, $\mathcal{J}_1$ is the space of trace-class operators and $\mathcal{J}_2$, the space of Hilbert-Schmidt operators. We write $\langle x \rangle = \sqrt{1 + \|x\|^2}$ and use $\langle X \rangle$ to denote the operator given by multiplication by the function $\langle x \rangle$.

For convenience we denote a constant $C$ depending only on the parameters $a, b, \ldots$ by $C_{a,b,\ldots}$.

We consider a random Schrödinger operator of the form

$$H_\omega = H_0 + \lambda V_\omega \quad \text{on } L^2(\mathbb{R}),$$

where $H_0$ is the free Hamiltonian, $\lambda$ measures the disorder strength which in the following we consider fix, and $V_\omega$, called random potential, is the operator multiplication by $V_\omega$, such that $\{V_\omega(x) : x \in \mathbb{R}^d\}$ is a real-valued measurable process on a complete probability space $(\Omega, \mathcal{F}, P)$ having the following properties:

(R) $V_\omega = V_\omega^+ + V_\omega^-$, where $V_\omega^+$ and $V_\omega^-$ are real valued measurable processes on $\Omega$ such that for $\mathbb{P}$-a.e. $\omega : 0 \leq V_\omega^+ \in L^1_{\text{loc}}(\mathbb{R}^d)$ and $V_\omega^-$ is relatively form-bounded with respect to $-\Delta$, with relative bound $< 1$, i.e. there are nonnegative constants $\Theta_1 < 1$ and $\Theta_2$ independent of $\omega$ such that for all $\psi \in \mathcal{D}(\nabla)$ we have

$$|\langle \psi, V_\omega^- \psi \rangle| \leq \Theta_1 \|\nabla \psi\|^2 + \Theta_2 \|\psi\|^2 \quad \text{for } \mathbb{P}\text{-a.e. } \omega$$

(IAD) There exists $\varrho > 0$ such that for any bounded sets $B_1, B_2 \subset \mathbb{R}^d$ with $\text{dist}(B_1, B_2) > \varrho$, the processes $\{V_\omega(x) : x \in B_1\}$ and $\{V_\omega(x) : x \in B_2\}$ are independent.

In the case $H_0 = H_B$, the unperturbed Landau Hamiltonian on $L^2(\mathbb{R}^2)$

$$H_B = (-i\nabla - A)^2 \quad \text{with } A = \frac{B}{2}(x_2, -x_1),$$

where $A$ is the vector potential and $B$ is the strength of the magnetic field, we ask $A(x) \in L^1_{\text{loc}}(\mathbb{R}^2; \mathbb{R}^2)$ to satisfy the diamagnetic inequality so we can obtain trace estimates for the Landau Hamiltonian from those of the Laplacian.

It follows that $H_\omega$ is a semibounded selfadjoint operator for $\mathbb{P}$-a.e. $\omega$. Moreover, the mapping $\omega \to H_\omega$ is measurable for $\mathbb{P}$-a.e. $\omega$, we denote its spectrum by $\sigma_\omega$.

In the usual setting for (ergodic) random Hamiltonians, $H_\omega$ satisfies a covariance condition with respect to the action of a family of unitary (translation) operators.
Anderson metal-insulator transition for non-ergodic operators

$U_x$, and its associated ergodic group of translations $\tau_x$ on the probability space $\Omega$. Throughout this paper we do not make any assumption on the ergodicity of $H_\omega$, so this covariance condition, \textit{a priori}, does not hold, i.e.

$$H_{\tau_x(\omega)} \neq U_\gamma H_\omega U_\gamma^*, \quad (2.3)$$

which makes $H_\omega$ a \textit{non-ergodic} random operator.

For the following assumption we need the notion of a \textit{finite volume operator}, the restriction of $H_\omega$ to either an open box $\Lambda_L(x)$ with Dirichlet boundary condition or to the closed box $\bar{\Lambda}_L(x)$ with periodic boundary conditions. In this way, we obtain a well defined random operator $H_{\omega,x,L}$ acting on $L^2(\Lambda_L(x))$ defined by

$$H_{\omega,x,L} = H_{0,x,L} + \lambda V_{\omega,x,L}.$$ 

we denote its spectrum by $\sigma_{\omega,x,L}$ and by $R_{\omega,x,L}(z) = (H_{\omega,x,L} - z)^{-1}$ its resolvent operator. We define the spectral projections $P_\omega(J) = \chi_J(H_\omega)$ and $P_{\omega,x,L}(J) = \chi_J(H_{\omega,x,L})$ for $J \subset \mathbb{R}$ a Borel set. When stressing the dependence on $\lambda$, it will be added to the subscript.

**Definition 1.**

(UWE) We say that $H_\omega$ satisfies a uniform Wegner estimate with Hölder exponent $s$ in an open interval $J$, i.e., for every $E \in J$ there exists a constant $Q_E$, bounded on compact subintervals of $J$ and $0 < s \leq 1$ such that

$$\sup_{x \in \mathbb{R}^d} \mathbb{E}\{\text{tr}(P_{\omega,x,L}(E - \eta, E + \eta))\} \leq Q_E \eta^s L^d, \quad (2.4)$$

for all $\eta > 0$ and $L \in 2\mathbb{N}$. It satisfies a uniform Wegner estimate at an energy $E$ if it satisfies a uniform Wegner estimate in an open interval $J$ such that $E \in J$.

To describe the dynamics, we consider the random moment of order $p \geq 0$ at time $t$ for the time evolution in the Hilbert-Schmidt norm, initially spatially localized in a square of side one around $u \in \mathbb{Z}^2$ and localized in energy by the function $\mathcal{X} \in C_{c+}(\mathbb{R})$, i.e.,

$$M_{u,\omega}(p, \mathcal{X}, t) = \|\langle X - u \rangle^{p/2} e^{-itH_\omega} \mathcal{X}(H_\omega)\chi_u\|_2^2. \quad (2.5)$$

We next consider its time average,

$$M_{u,\omega}(p, \mathcal{X}, T) = \frac{2}{T} \int_0^T e^{-2t/T} M_{u,\omega}(p, \mathcal{X}, t)dt. \quad (2.6)$$

**Definition 2.**

1. We say that $H_\omega$ exhibits strong Hilbert-Schmidt (HS-) dynamical localization in the open interval $I$ if for all $\mathcal{X} \in C_{c+}(I)$ we have

$$\sup_{u \in \mathbb{Z}^2} \mathbb{E}\{\sup_{t \in \mathbb{R}} M_{u,\omega}(p, \mathcal{X}, t)\} < \infty \quad \text{for all } p \geq 0.$$
We say that $H_\omega$ exhibits strong Hilbert-Schmidt (HS-) dynamical localization at an energy $E$ if there exists an open interval $I$ with $E \in I$, such that there is strong HS-dynamical localization in the open interval.

2. The strong insulator region for $H_\omega$ is defined as

$$\Sigma_{SI} = \{ E \in \mathbb{R} : H_\omega \text{ exhibits strong HS-dynamical localization at } E \}$$  \hspace{1cm} (2.7)

Note that if there exists a $\delta > 0$ such that $\text{dist} (E, \sigma_\omega) > 0$ for almost every $\omega$, then $E \in \Sigma_{SI}$.

As we shall see, the existence of such a region for random Schrödinger operators is the consequence of the applicability of the Bootstrap MSA adapted to the non ergodic setting (Theorem 2.1).

Given $\theta > 0$, $E \in \mathbb{R}$, $x \in \mathbb{Z}^d$ and $L \in \mathbb{6N}$, we say that the box $\Lambda_L(x)$ is $(\theta, E)$-suitable for $H_\omega$ if $E \not\in \sigma_{\omega,x,L}$ and

$$\| \Gamma_{x,L} R_{x,L}(E) \chi_{x,L/3} \|_{x,L} \leq \frac{1}{L^\theta},$$

where $\Gamma_{x,L} = \chi_{\Lambda_{L-1}(x) \setminus \Lambda_{L-3}(x)}$. If we replace the polynomial decay $1/L^\theta$ by $e^{-mL/2}$ we say that the box $\Lambda_L(x)$ is $(m, E)$-regular for $H_\omega$.

The following theorem is a reformulation of Theorem 3.4 and Corollary 3.10 [GK1] in a non ergodic setting.

**Theorem 2.1.** Let $H_\omega$ be a random Schrödinger operator satisfying a uniform Wegner estimate in an open interval $J$ with Hölder exponent $s$ and assumptions $(R)$, $(IAD)$. Given $\theta > d$, for each $E \in J$ there exists a finite scale $L_0(E) = L(\theta, E, Q_E, d, s)$, bounded in compact subintervals of $J$, such that if for $L > L_0(E)$ the following holds

$$\inf_{x \in \mathbb{Z}^d} \mathbb{P}\{ \Lambda_L(x) \text{ is } (\theta, E)\text{-suitable} \} > 1 - \frac{1}{841}d,$$ \hspace{1cm} (2.8)

then there exists $\delta_0 > 0$ and $C_\zeta > 0$ such that

$$\sup_{u \in \mathbb{Z}^d} \mathbb{E} \left( \sup_{\| f \| \leq 1} \| \chi_{x+u} f (H_\omega) P_\omega (I(\delta_0)) \chi_u \|_2^2 \right) \leq C_\zeta e^{-|x|\zeta},$$ \hspace{1cm} (2.9)

for $0 < \zeta < 1$, where $I(\delta_0) = [E - \delta_0, E + \delta_0]$. Moreover, $E \in \Sigma_{SI}$ and we have the following properties,

(SUDEC) **Summable uniform decay of eigenfunction correlations:** for a.e. $\omega \in \Omega$, the Hamiltonian $H_\omega$ has pure point spectrum in $I \subset \Sigma_{SI}$ with finite multiplicity. Let $\{ \epsilon_{n,\omega} \}_{n \in \mathbb{N}}$ be an enumeration of the distinct eigenvalues of $H_\omega$ in $I$. Then for each $\zeta \in [0, 1]$ and $\epsilon > 0$ we have, for every $x, u \in \mathbb{Z}^d$,

$$\| \chi_{x+u} \phi \| \| \chi_u \varphi \| \leq C_{T, \zeta, \epsilon, \omega} \| T_{u}^{-1} \phi \| \| T_{u}^{-1} \varphi \| \langle x + u \rangle^{\frac{d+\epsilon}{2}} \langle u \rangle^{\frac{d-\epsilon}{2}} e^{-|x|\zeta},$$ \hspace{1cm} (2.10)

for all $\phi, \varphi \in \text{Ran } P_\omega (\{ \epsilon_{n,\omega} \})$ (see Section 3).
Anderson metal-insulator transition for non ergodic operators

(DFP) Decay of the Fermi projections: for \( E \in \Sigma_{SI} \) and for any \( \zeta \in ]0,1[ \) we have
\[
\sup_{u \in \mathbb{Z}^d} \mathbb{E}\{ \| \chi_{x+u} P_\omega((\infty, E]) \chi_u \|_2^2 \} \leq C_{\zeta, \lambda, E} e^{-|x|\zeta}
\] (2.11)
where the constant \( C_{\zeta, E} \) is locally bounded in \( E \).

Remark 2.1. The condition (2.8) is called the initial length scale estimate (ILSE) of the Bootstrap MSA. In practice is often useful to prove the equivalent estimate [GK3, Theorem 4.2]: For some \( \theta > d \), we have
\[
\limsup_{L \to \infty} \inf_{x \in \mathbb{Z}^d} \mathbb{P}\{ \Lambda_L(x) \text{ is } (\theta, E)-suitable \} = 1.
\] (2.12)

Definition 3. The multiscale analysis region for \( H_\omega \) is defined as the set of energies where we can perform the bootstrap MSA, i.e.
\[
\Sigma_{MSA} = \{ E \in \mathbb{R} : H_\omega \text{ satisfies a uniform Wegner estimate at } E \text{ and } (ILSE) \text{ holds for some } L > L_\theta(E) \}. \] (2.13)

By Theorem 2.1 we have \( \Sigma_{MSA} \subset \Sigma_{SI} \).

We introduce the (lower) transport exponent in the annealed regime:
\[
\beta(p, \mathcal{X}) = \liminf_{T \to \infty} \frac{\log_+ \sup_{u} \mathbb{E}(\mathcal{M}_{u, \omega}(p, \mathcal{X}, T))}{p \log T}
\] (2.14)
for \( p \geq 0 \), \( \mathcal{X} \in C^\infty_{\mathbb{R}_+}(\mathbb{R}) \), where \( \log_+ t = \max\{0, \log t\} \), and define the \( p \)-th local transport exponent at the energy \( E \), by
\[
\beta(p, E) = \inf_{I \ni E} \sup_{\mathcal{X} \in C^\infty_{\mathbb{R}_+}(I)} \beta(p, \mathcal{X}),
\] (2.15)
where \( I \) denotes an open interval. The exponents \( \beta(p, E) \) provide a measure of the rate of transport in wave packets with spectral support near \( E \). Since they are increasing in \( p \), we define the local (lower) transport exponent \( \beta(E) \) by
\[
\beta(E) = \lim_{p \to \infty} \beta(p, E) = \sup_{p > 0} \beta(p, E).
\] (2.16)

With the help of this transport rate we can define two complementary sets in the energy axis for fixed \( B > 0 \), \( \lambda > 0 \), the region of dynamical localization
\[
\Xi^{DL} = \{ E \in \mathbb{R} : \beta(E) = 0 \},
\] (2.17)
also called the trivial transport region (TT) in [GK3] and the region of dynamical delocalization
\[
\Xi^{DD} = \{ E \in \mathbb{R} : \beta(E) > 0 \},
\] (2.18)
also called the weak metallic transport region (WMT), in [GK3]. Recalling Theorem 2.1, we have that \( \Sigma_{MSA} \subset \Sigma_{SI} \subset \Xi^{DL} \).

The following result is an improvement of [GK3, Theorem 2.11] for the non ergodic setting
Theorem 2.2. Let $H_\omega$ be a Schrödinger operator satisfying a uniform Wegner estimate with Hölder exponent $s$ in an open interval $J$ and assumptions (R), (IAD). Let $\mathcal{X} \in C^{\infty}_c(\mathbb{R})$ with $\mathcal{X} \equiv 1$ on some open interval $J \subset J$, $\alpha \geq 0$ and $p > p(\alpha, s) := \frac{12}{s} + 2\alpha \frac{d}{s}$. If
\[
\liminf_{T \to \infty} \sup_{u \in \mathbb{Z}^d} \frac{1}{T^s} E (\mathcal{M}_{u, \omega}(p, \mathcal{X}, T)) < \infty, \tag{2.19}
\]
then $J \subset \Sigma_{MSA}$. In particular, it follows that (2.19) holds for any $p \geq 0$.

Moreover, we can extend this result to a quenched regime, a new feature in both ergodic and non-ergodic situations:

Theorem 2.3. Let $H_\omega$ be a Schrödinger operator satisfying a uniform Wegner estimate with Hölder exponent $s$ in an open interval $J$ and assumptions (R), (IAD). Let $\mathcal{X} \in C^{\infty}_c(\mathbb{R})$ with $\mathcal{X} \equiv 1$ on some open interval $J \subset J$, $\alpha \geq 0$ and $p > p(\alpha, s) := \frac{15}{d} + 2\alpha \frac{d}{s}$. If
\[
\liminf_{T \to \infty} \sup_{u \in \mathbb{Z}^d} T^{\alpha} \mathbb{P}(\mathcal{M}_{u, \omega}(p, \mathcal{X}, T) > T^\alpha) = 0, \tag{2.20}
\]
then $J \subset \Sigma_{MSA}$. In particular, it follows that (2.20) holds for any $p \geq 0$.

Remark 2.2. If the moment increases almost surely at any other rate less than polynomial, this implies in particular condition (2.20) for some $\alpha > 0$, and the result follows.

Moreover, if condition (2.28) in [GK3, Theorem 2.11] holds for $\alpha > 0$ and $p > p(\alpha, s) + d$, then condition (2.20) holds for $\alpha' = \alpha + \delta$ and the same $p$, where $0 < s/2 < \delta < \frac{(p-p(\alpha, s))}{2\alpha}$ and $p > p(\alpha', s)$, since by Chebyshev’s inequality we have
\[
T^{\alpha'} \sup_{u} \mathbb{P}(\mathcal{M}_{u, \omega}(p, \mathcal{X}, T) > T^{\alpha'}) \leq \frac{1}{T^{\alpha + \delta - s/2}} \sup_{u} E (\mathcal{M}_{u, \omega}(p, \mathcal{X}, T)) \text{ for all } T > 0. \tag{2.21}
\]
This also shows that (2.20) is indeed a weaker condition than (2.19).

By Theorem 2.2 we have that $\Xi^{DL} \subset \Sigma_{MSA}$, so Theorems 2.8 and 2.10 of [GK3] hold in our setting. Thus, the local transport exponent $\beta(E)$ gives a characterization of the metal-insulator transport transition for non ergodic models as for the usual ergodic setting. Moreover, if we consider only the random moments in a quenched regime to behave asymptotically slow, we see the same behavior for the ergodic and non ergodic setting, in agreement with the annealed regime.

3. Proof of Theorem 2.1

3.1. Generalized eigenfunction expansion. We have to construct a generalized eigenfunction expansion adapted to the non ergodic case. Compared to [GK3, Section 2.3] we shall use a family of weighted spaces rather than just one in particular, using translations in $u \in \mathbb{Z}^2$ of the operator $T$ defined there and thus without using translation invariance in the proofs.

Let $T_u$ be the operator in $\mathcal{H}$ given by multiplication by the function $(1+|x-u|^2)^\nu$, where $\nu > d/4, u \in \mathbb{Z}^2$. We define the weighted spaces $\mathcal{H}_\pm^u$ as
\[ \mathcal{H}_u^\pm = L^2(\mathbb{R}^d, (1 + |x - u|^2)^{\nu} dx; \mathbb{C}). \] (3.1)

The sequilinear form

\[ \langle \phi_1, \phi_2 \rangle_{\mathcal{H}_u^+, \mathcal{H}_u^-} = \int \phi_1 \phi_2(x) dx \quad \text{for } \phi_1 \in \mathcal{H}_u^+, \phi_2 \in \mathcal{H}_u^- \]

makes \( \mathcal{H}_u^+ \) and \( \mathcal{H}_u^- \) conjugates dual to each other and we denote by \( \dagger \) the conjugation with respect to this duality. The natural injections \( \iota_u^+ : \mathcal{H}_u^+ \to \mathcal{H} \) and \( \iota_u^- : \mathcal{H} \to \mathcal{H}_u^- \) are continuous with dense range, with \( \iota_u^\dagger = \iota_u \). The operators \( T_{u,+} = \iota_u^+ \) and \( T_{u,-} : \mathcal{H} \to \mathcal{H}_u^- \) defined by \( T_{u,+} = T_u \iota_u^+ \) and \( T_{u,-} = \iota_u^- T_u \) on \( \mathcal{D}(T_u) \) are unitary with \( T_{u,-} = T_{u,+}^\dagger \). Note that

\[ \| \chi_{x,L} \|_{\mathcal{H}, \mathcal{H}_u^+} = \| \chi_{x,L} \|_{\mathcal{H}_u^-, \mathcal{H}} \leq C_{L,d,\nu}(1 + |x - u|^2)^\nu, \] (3.2)

for all \( x \in \mathbb{R}^d \) and \( L > 0 \).

With this redefinition we can follow [GK1], restating assumption GEE for non ergodic operators. We consider a fixed open interval \( I \) and a bounded function \( f \) such that \( \iota_u^f : \mathcal{H}_u^+ \to \mathcal{H} \) and \( \iota_u^- : \mathcal{H} \to \mathcal{H}_u^- \) are bounded and \( \iota_u^f(x) \in \mathcal{D}(\mathcal{F}) \) for every bounded set \( \mathcal{F} \). Thus with probability one, for all \( u \)

\[ \iota_u^f(\mathcal{F}) = \iota_u^f(x), \quad u, \omega \text{ a.e.} \]

and \( \mathcal{F} \in \mathcal{D}(\mathcal{F}) \) is the spectral projection of the operator \( \mathcal{F} \) on a Borel set \( \mathcal{F} \subseteq \mathbb{R} \).

(UGEE) For some \( \nu > d/4 \), the set \( \mathcal{D}_u = \{ \phi \in \mathcal{D}(\mathcal{F}) \cap \mathcal{H}_u^+ : \mathcal{F} \iota_u^f \phi \in \mathcal{H}_u^+ \} \) is dense in \( \mathcal{H}_+ \) and an operator core for \( \mathcal{F} \) for \( \mathbb{P} - \text{a.e. } \omega \) and all \( u \). There exists a bounded function \( f \), strictly positive on the spectrum of \( \mathcal{F} \) such that, for bounded \( u \)

\[ \sup_u \text{tr}_{\mathcal{H}} (T_u^{-1} f(H_u) P_u(\mathcal{I}) T_u^{-1}) < \infty, \] (3.3)

and \( \mathbb{P}-\text{a.e. } \omega \).

If UGEE holds, for almost every \( \omega \) and all \( u \) we have

\[ \text{tr}_{\mathcal{H}} (T_u^{-1} P_u(J \cap \mathcal{I}) T_u^{-1}) < \infty, \] (3.4)

for all bounded sets \( J \). Thus with probability one, for all \( u \)

\[ \mu_{u,\omega}(J) = \text{tr}_{\mathcal{H}} (T_u^{-1} P_u(J \cap \mathcal{I}) T_u^{-1}) \] (3.5)

is a spectral measure for the restriction of \( \mathcal{F} \) to the Hilbert space \( P_u(\mathcal{I}) \mathcal{H} \), and for every bounded set \( J \),

\[ \mu_{u,\omega}(J) < \infty. \] (3.6)

Then, we have a generalized eigenfunction expansion as in [GK1] Section 2: for every \( u \), there exists a \( \mu_{u,\omega} \)-locally integrable function \( P_{u,\omega}(\lambda) \) from \( \mathbb{R} \) into \( T_{\mathcal{I}}(\mathcal{H}_u^+, \mathcal{H}_u^-) \), the space of trace class operators from \( \mathcal{H}_u^+ \) to \( \mathcal{H}_u^- \), with

\[ P_{u,\omega}(\lambda) = P_{u,\omega}(\lambda)^\dagger \] (3.7)

and

\[ \text{tr}_{\mathcal{H}} (T_{u,-} P_{u,\omega}(\lambda) T_{u,+}) = 1 \quad \text{for } \mu_{u,\omega}-\text{a.e. } \lambda, \] (3.8)

such that

\[ \iota_u^f(\mathcal{F}) = \int \mathcal{P}_{u,\omega}(\lambda) d\mu_{u,\omega}(\lambda) \quad \text{for bounded Borel sets } J \] (3.9)

where the integral is the Bochner integral of \( T_{\mathcal{I}}(\mathcal{H}_u^+, \mathcal{H}_u^-) \)-valued functions.
The following (a restatement of assumption SGEE), is a stronger version of UGEE:

\textbf{(USGEE)} We have that (UGEE) holds with

\[
\sup_u \mathbb{E} \left( \left[ \text{tr}_{\mathcal{H}} \left( T_u^{-1} f(H_\omega) P_\omega(I) T_u^{-1} \right) \right]^2 \right) < \infty. \tag{3.10}
\]

So for every bounded set \( J \),

\[
\sup_u \mathbb{E}(\mu_{u,\omega}(J)^2) < \infty. \tag{3.11}
\]

3.2. Kernel Decay and Dynamical Localization. Following the arguments in [GK1] for ergodic operators, we can show that HS-strong dynamical localization is a consequence of the applicability of the Bootstrap MSA for the non ergodic setting ([GK1, Theorem 3.4] with the stronger initial ILSE (2.8) instead of the original one).

We can restate Lemma 2.5 and Lemma 4.1 [GK1] as follows, extending the proofs to our new definitions,

\textbf{Lemma 3.1.} Let \( H_\omega \) be a random operator satisfying assumption GEE. We have with probability one, for all \( u \), that for \( \mu_{u,\omega} \)-almost every \( \tilde{\lambda} \),

\[
\| \chi_x P_{u,\omega}(\tilde{\lambda}) \chi_y \|_1 \leq C (1 + |x - u|^2)^\nu (1 + |y - u|^2)^\nu \tag{3.12}
\]

for all \( x, y \in \mathbb{R}^d \), with \( C \) a finite constant independent of \( \tilde{\lambda}, \omega \) and \( u \).

Suppose, moreover, that assumption EDI in [GK1] is satisfied in some compact interval \( I_0 \subset \mathcal{I} \). Given \( I \subset I_0 \), \( m > 0 \), \( L \in 6\mathbb{N} \) and \( x, y \in \mathbb{Z}^d \), if \( \omega \in R(m, L, I, x, y) \), with \( R(m, L, I, x, y) \) defined as in (3.18), then

\[
\| \chi_x P_{u,\omega}(\tilde{\lambda}) \chi_y \|_2 \leq C e^{-m L/4} (1 + |x - u|^2)^\nu (1 + |y - u|^2)^\nu, \tag{3.13}
\]

for \( \mu_{u,\omega} \)-almost all \( \tilde{\lambda} \in I \), with \( C = C(m, d, \nu, \tilde{\gamma}_{I_0}) \), where \( \tilde{\gamma}_{I_0} \) is the constant on assumption EDI.

\textbf{Proof of Theorem 2.1.} To apply the MSA in the non ergodic case we first need to verify for an operator satisfying only properties (R), (IAD) and (UWE), the standard assumptions (SLI), (EDI) [GK1], plus (UNE) and (USGEE), which are stronger assumptions than those stated in the mentioned article.

As for (SLI) and (EDI), these are deterministic assumptions that hold for each \( \omega \in \Omega \) and their proof, done in [GK3, Appendix A], relies on property (R), with no use of ergodicity. In the same appendix we see that assumption (NE) is uniform on cubes centered in \( x \in \mathbb{R}^d \) and relies on property (R) so it holds in our more general setting. The same is true for [GK3, Lemma A.3], and can be extended in an analog way to the case \( H_0 = H_B \) [BGKS, Section 2.1], proving the first part of (USGEE) (and UGEE)).

As for the trace estimate (3.10), for the case \( H_0 = -\Delta \) it follows from [GK3, Lemma A.4] and [KKS, Theorem 1.1], taking \( V = \langle X - u \rangle^{-2\nu} \) there, the result being uniform in \( u \). It can be extended to the case \( H_0 = H_B \) as in [BGKS, Proposition 2.1].

To obtain the basic result of MSA [GK1, Theorem 3.4] we need conditions (IAD), (SLI), (UNE) and (UWE) to follow an analog iteration procedure. Recall that in
their article, Germinet and Klein take two versions of MSA by Figotin and Klein, improve their estimates yielding other two MSA and then bootstrapping them to obtain the strongest result out of the weakest hypothesis, so in order to extend this results to the non ergodic setting we reformulate this methods. Each step consists of a purely geometric deterministic part where we use SLI, and therefore it does not depend on the placement of the boxes were we perform the procedure, and a probabilistic part, where we use (UWE) instead of (WE) to obtain an estimate on the probability of having bad events, in a stronger sense than the usual, that is, uniform with respect to the placement of the box in space.

We begin with the single energy multiscale analyses, Theorems 5.1 and 5.6 [GK1], which in our non-ergodic setting consists in estimating the decay of

$$p_L = \sup_{x \in \mathbb{Z}^d} p_{x,L}, \quad (3.14)$$

where

$$p_{x,L} = \mathbb{P}\{\Lambda_L(x) \text{ is bad}\} \quad (3.15)$$

(here a box is bad if it is not $(\theta, E)$-suitable for $H_\omega$). In the ergodic case we need only to consider $p_{0,L}$. Hypothesis (2.8) ensures we can follow the same iteration procedure in all boxes centered in $x \in \mathbb{Z}^d$, where $p_{0,L}$ is thus replaced by $p_L$. We use properties SLI and (UWE) instead of WE, and the deterministic arguments remain the same, since they do not depend on the location of the box. Considering a Hölder exponent $s$ in WE implies that the choice of the initial length scale will also depend on $s$.

Next we consider the energy interval multiscale analyses, Theorems 5.2 and 5.7 [GK1], which in our general setting consists in estimating

$$\hat{p}_L = \sup_{x,y \in \mathbb{Z}^d, |x-y| > L+\rho} \hat{p}_{x,y,L}, \quad (3.16)$$

with

$$\hat{p}_{x,y,L} = \mathbb{P}\{R(m,L,I(\delta_0),x,y)^c\} \quad (3.17)$$

where $I(\delta_0) = [E - \delta_0, E + \delta_0]$, for some $\delta_0 > 0$ and

$$R(m,L,I(\delta_0),x,y) = \{\omega : \text{for every } E \in I(\delta_0), \Lambda_L(x) \text{ or } \Lambda_L(y) \text{ is good}\} \quad (3.18)$$

(here a box is good if it is $(m,E)$-regular for $H_\omega$, with $m$ to be specified later). In the ergodic case it suffices to consider $\hat{p}_{x,y,L}$. We can thus follow the original iteration procedure on this estimate, replacing $\hat{p}_{x,y,L}$ by $\hat{p}_L$, obtaining an analog of [GK1] Eq. 3.4], i.e., there exists $\delta_0 > 0$ such that given any $\zeta$, $0 < \zeta < 1$ there is a length scale $L_0 < \infty$ and a mass $m_\zeta = m(\zeta, L_0) > 0$ such that if we set $L_{k+1} = [L_k^\alpha]_{\mathbb{N}}$, $0 < \alpha < \zeta^{-1}$, $k = 0, 1, 2, ...$ we have

$$\inf_{x,y \in \mathbb{Z}^d, |x-y| > L+\rho} \mathbb{P}\{R(m_\zeta,L_k,I(\delta_0),x,y)\} \geq 1 - e^{-L_k^\zeta}. \quad (3.19)$$

To derive results on the spectrum and the dynamics of the operator from this estimate we need to consider also conditions EDI and USGEE. Thus, with Lemma 3.1 in hand, (3.19) and USGEE we can follow the proof of [GK1] Theorem 3.8] with
minor modifications. We want to show that if \((3.19)\) holds we have that for any \(0 < \zeta < 1\), there is a finite constant \(C_\zeta\) such that

\[
\sup_u \mathbb{E} \left( \sup_{\|f\| \leq 1} \|\chi_{x+u} f(H_\omega) P_\omega(I(\delta_0)) \chi_u\|_2^2 \right) \leq C_\zeta e^{-|x|^\zeta}, \tag{3.20}
\]

For this, we consider the pair of points \(x, y\) as the pair \(x + u, u\), and fix \(x \in \mathbb{Z}^d\) and \(k\) such that \(L_{k+1} + \varrho > |x| > L_k + \varrho\). We split the expectation in \((3.20)\) in two parts: the first one over the set \(R(m_\zeta, L_k, I(\delta_0), x + u, u)\) and the second one over its complement, which has probability less than \(e^{-L_\zeta^2}\), uniformly in \(u\), by \((3.19)\).

We follow the arguments in [GK1, Eq. 4.8-4.13]. By \((3.9)\) and Lemma 3.1 we can write, for a positive constant \(C_1\),

\[
\sup_{\|f\| \leq 1} \|\chi_{x+u} f(H_\omega) P_\omega(I(\delta_0)) \chi_u\|_2 \leq C_1 e^{-L_\zeta^2} \mu_{u, \omega}(I). \tag{3.21}
\]

This implies,

\[
\sup_u \mathbb{E} \left( \sup_{\|f\| \leq 1} \|\chi_{x+u} f(H_\omega) P_\omega(I(\delta_0)) \chi_u\|_2^2 ; R(m_\zeta, L_k, I(\delta_0), x + u, u) \right)
\leq C_1^2 \sup_u \mathbb{E} \{ (\mu_{u, \omega}(I(\delta_0)))^2 \} e^{-2L_\zeta^2}, \tag{3.22}
\]

As for the expectation over \(R(m_\zeta, L_k, I(\delta_0), x + u, u)^c\), \((3.19)\) implies that

\[
\sup_u \mathbb{P}(R(m_\zeta, L_k, I(\delta_0), x + u, u)^c) < e^{-L_\zeta^2}
\]

this yields,

\[
\sup_u \mathbb{E} \left( \sup_{\|f\| \leq 1} \|\chi_{x+u} f(H_\omega) P_\omega(I(\delta_0)) \chi_u\|_2^2 ; R(m_\zeta, L_k, I(\delta_0), x + u, u)^c \right)
\leq 4^\nu \sup_u \mathbb{E} \{ (\mu_{u, \omega}(I(\delta_0)))^2 \} \frac{1}{4} e^{-\frac{1}{4}L_\zeta^2} \tag{3.23}
\]

where we use the fact that by \((3.5)\) we can write

\[
\|\chi_{x+u} f(H_\omega) P_\omega(I(\delta_0)) \chi_u\|_2^2 \leq \|f\|^2 \|P_\omega(I(\delta_0)) \chi_u\|_2^2 \leq C \|f\| \mu_{u, \omega}(I(\delta_0)) \tag{3.24}
\]

Combining \((3.22)\) and \((3.23)\), using USGEE we obtain the desired decay, namely \((3.20)\).

Now we can prove a strong version of dynamical localization as in [GK1, Corollary 3.10]. Notice that, if \(p > 2\)

\[
\langle X - u \rangle^p = \sum_{x \in \mathbb{Z}^d} (1 + \|y - u\|^2)^{p/2} \chi_x(y) \leq C_d \sum_{x \in \mathbb{Z}^d} (1 + \|x - u\|^2)^{p/2} \chi_x(y)
= C_d \sum_{x \in \mathbb{Z}^d} (1 + \|x\|^2)^{p/2} \chi_{x+u}(y), \tag{3.25}
\]

so we have,
\[ \|X - u\|^p f(H_\omega)P_\omega(I(\delta_0))\chi_u\|_2^2 \]
\[ = \text{tr}[\chi_u f(H_\omega)P_\omega(I(\delta_0))(X - u)^p P_\omega(I(\delta_0))f(H_\omega)\chi_u] \]
\[ \leq C_d \sum_{x \in \mathbb{Z}^d} (1 + \|x\|^2)^{p/2} \|\text{tr}[\chi_u f(H_\omega)P_\omega(I(\delta_0))\chi_{x+u}P_\omega(I(\delta_0))f(H_\omega)\chi_u]\|_2^2 \]
\[ = C_d \sum_{x \in \mathbb{Z}^d} (1 + \|x\|^2)^{p/2} \|\chi_{x+u}f(H_\omega)P_\omega(I(\delta_0))\chi_u\|_2^2 \quad (3.26) \]

Taking the expectation and then the supremum over \( u \in \mathbb{Z}^2 \), by (3.20) we obtain strong HS-dynamical localization in the energy interval \( I(\delta_0) \).

Following the proof of [GK4 Corollary 3], after adapting [GK4 Theorem 1] to our setting we obtain the summable uniform decay of eigenfunction correlations SUDEC. As for property DFP, it is a consequence of (3.20) combined with [BGK, Theorem 1.4], which is a deterministic result also valid in our setting, in the lines of [GK4 Theorem 3].

□

4. Proofs of Theorems 2.2 and 2.3

Here we can proceed as in [GK3]. First we state the following Lemma, which is an intermediate result in the proof of [GK3 Lemma 6.4], adapted to the (UWE) with Hölder exponent \( s \). We consider a cube \( \Lambda_L(x) \) with arbitrary \( x \) so we omit it from the notation.

**Lemma 4.1.** Let \( H_\omega \) be a random Schrödinger operator satisfying a uniform Wegner estimate in an open interval \( I \), with Wegner constant \( Q_E \) and Hölder exponent \( s \). Let \( p_0 > 0 \) and \( \gamma > d \). For each \( E \in I \), there exists \( \mathcal{L} = \mathcal{L}(d, E, Q_E, \gamma, p_0, s) \) bounded on compact subsets of \( I \), such that, given \( L \in 2\mathbb{N} \) with \( L \geq \mathcal{L} \), and subsets \( B_1 \) and \( B_2 \) of \( \Lambda_L \) (not necessarily disjoint) with \( B_1 \subset \Lambda_{L-5/2} \) and \( \Lambda_{L-1} \setminus \Lambda_{L-3} \subset B_2 \), then for each \( \alpha > 0 \) and \( 0 < \epsilon < 1 \) we have

\[ \mathbb{P}\left( \|\chi_2 R_{\omega,L}(E + i\epsilon)\chi_1\|_L > \frac{\alpha}{4} \right) \leq \mathbb{P}\left( \|\chi_2 R_{\omega}(E + i\epsilon)\chi_1\|_L > \frac{\alpha}{L^{d/2}} \right) + \frac{p_0}{10}, \quad (4.1) \]

and

\[ \mathbb{P}\left( \|\chi_2 R_{\omega,L}(E)\chi_1\|_L > \frac{\alpha}{2} \right) \leq \mathbb{P}\left( \|\chi_2 R_{\omega}(E + i\epsilon)\chi_1\|_L > \frac{\alpha}{L^{d/2}} \right) + Q_E \left( \frac{4\epsilon}{\alpha} \right)^{s/2} L^{d} + \frac{p_0}{10}, \quad (4.2) \]

where \( \chi_i \) stands for \( \chi_{B_i}, i = 1, 2 \).

**Proof of Theorem 2.2.** By the same arguments used in [GK3 Theorem 4.2], it suffices to show that, under condition (2.20), for each \( E \in J \) there is some \( \theta > d/s \) such that

\[ \limsup_{L \to \infty} \inf_{y \in \mathbb{Z}^d} \mathbb{P}\left( \|\Gamma_{y,L} R_{\omega,y,L}(E)\chi_{y,L/3}\|_L \leq \frac{1}{L^\theta} \right) = 1, \quad (4.3) \]

i.e. the starting condition for the bootstrap MSA, (2.8), in its strong version, holds at some finite scale \( L > \mathcal{L}_0(E) \).
Let $E \in J$, $\theta > d/s$ and $L \in 6 \mathbb{N}$. We start by estimating

$$P_{E,L} := \sup_y \mathbb{P} \left( \| \Gamma_{y,L} R_{\omega,L}(E) \chi_{y,L/3} \|_{y,L} > \frac{1}{L^{\theta}} \right).$$  \hspace{1cm} (4.4)

We decompose as in [GK3, Eq. 6.26-6.28], using

\[ \chi_{y,L} = \chi_{y,2L/3} + \chi_{y,L\setminus 2L/3}, \]  

where $\chi_{y,L\setminus 2L/3} = \chi_{y,\Lambda_L \setminus \Lambda_{2L/3}}$

so (for simplicity we omit the subscript $y$ from the norm)

\[ P_{E,L} \leq \sup_y \mathbb{P} \left( \frac{1}{4L^{\theta}} < \left\| \Gamma_{y,L} R_{\omega,L}(E + i\epsilon) \chi_{y,L/3} \right\|_{L} \right) \hspace{1cm} (4.5) \]

\[ + \sup_y \mathbb{P} \left( \frac{1}{2L^{\theta}} < \epsilon \left\| R_{\omega,L}(E + i\epsilon) \|_{L} \| \Gamma_{y,L} R_{\omega,L}(E) \chi_{y,2L/3} \|_{L} \right\| \right) \hspace{1cm} (4.6) \]

\[ + \sup_y \mathbb{P} \left( \frac{1}{4L^{\theta}} < \epsilon \left\| R_{\omega,L}(E) \|_{L} \| \chi_{y,L\setminus 2L/3} R_{\omega,L}(E + i\epsilon) \chi_{y,L/3} \|_{L} \right\| \right) \hspace{1cm} (4.7) \]

To estimate the first term we use (4.1) with $\alpha = L^{-\theta}$. As for the rest, we use (4.2) and (4.1), respectively, with $\alpha = 1$, plus the uniform Wegner estimate. We obtain

\[ P_{E,L} \leq \sup_y \mathbb{P} \left( \frac{1}{L^{\theta+\gamma}} < \left\| \Gamma_{y,L} R_{\omega}(E + i\epsilon) \chi_{y,L/3} \right\| \right) \hspace{1cm} (4.8) \]

\[ + \sup_y \mathbb{P} \left( \frac{1}{L^{\gamma}} < \left\| \Gamma_{y,L} R_{\omega}(E + i\epsilon) \chi_{y,2L/3} \right\| \right) \hspace{1cm} (4.9) \]

\[ + \sup_y \mathbb{P} \left( \frac{1}{L^{\gamma}} < \left\| \chi_{y,L\setminus 2L/3} R_{\omega}(E + i\epsilon) \chi_{y,L/3} \right\| \right) \hspace{1cm} (4.10) \]

\[ + Q_I (4\epsilon)^{s/2} L^d + 2Q_I \epsilon^s L^{\theta s + d} + \frac{3p_0}{10} \hspace{1cm} (4.11) \]

for $L > \mathcal{L}$, with $\mathcal{L}$ as in Lemma 4.1 where $\gamma > d/s$, $0 < \epsilon \leq 1$, $0 < p_0 < 1$ and $Q_I = \sup_{E \in I} Q_E < \infty$. Set

\[ L = L(I, \epsilon) := \left\lfloor \left( \frac{p_0}{20Q_I \epsilon^s} \right)^{1/(\theta s + d)} \right\rfloor_{6 \mathbb{N}}, \hspace{1cm} (4.12) \]

so that

\[ Q_I (4\epsilon)^{s/2} L^d \leq \frac{p_0}{10} \quad \text{and} \quad 2Q_I \epsilon^s L^{\theta s + d} \leq \frac{p_0}{10}. \]

We first estimate,

\[ \sup_y \mathbb{P} \left( \frac{1}{L^{\theta+\gamma}} < \left\| \Gamma_{y,L} R_{\omega}(E + i\epsilon) \chi_{y,L/3} \right\| \right). \hspace{1cm} (4.13) \]

To do this, we decompose the norm using the function $\mathcal{X}(H_\omega)$ that localizes in energy, yielding

\[ \sup_y \mathbb{P} \left( \frac{1}{2L^{\theta+\gamma}} < \left\| \Gamma_{y,L} R_{\omega}(E + i\epsilon) \mathcal{X}(H_\omega) \chi_{y,L/3} \right\| \right) \hspace{1cm} (4.14) \]

\[ + \sup_y \mathbb{P} \left( \frac{1}{2L^{\theta+\gamma}} < \left\| \Gamma_{y,L} R_{\omega}(E + i\epsilon)(1 - \mathcal{X}(H_\omega)) \chi_{y,L/3} \right\| \right). \hspace{1cm} (4.15) \]
For the second term we use Chebyshev’s inequality and follow [GK3, Eq. 6.32 - 6.34], so we can bound it by $p_0/12$.

Estimating in the same way the terms (4.9) and (4.10) we obtain that for $L$ big enough,

$$P_{E,L} \leq \sup_y P \left( \frac{1}{2L^{\theta+\gamma}} < \| \Gamma_{y,L} R_\omega (E + i\epsilon) \chi (H_\omega) \chi_{y,L/3} \| \right) \quad (4.16)$$

$$+ \sup_y P \left( \frac{1}{2L^{\gamma}} < \| \Gamma_{y,L} R_\omega (E + i\epsilon) \chi (H_\omega) \chi_{y,2L/3} \| \right) \quad (4.17)$$

$$+ \sup_y P \left( \frac{1}{2L^{\gamma}} < \| \chi_{y,L/3} (E + i\epsilon) \chi (H_\omega) \chi_{y,L/3} \| \right) + \frac{3p_0}{4}. \quad (4.18)$$

As for the first term,

$$P \left( \frac{1}{2L^{\theta+\gamma}} < \| \Gamma_{y,L} R_\omega (E + i\epsilon) \chi (H_\omega) \chi_{y,L/3} \| \right) \leq 2L^{\theta+\gamma} \sum_{u \in \tilde{\Lambda}_{L/3}(y)} E (\| (X - u)^{p/2} R_\omega (E + i\epsilon) \chi (H_\omega) \chi_u \|^2_2) \quad (4.19)$$

$$\leq 2L^{\theta+\gamma} \int_{\mathbb{R}} E (\| (X - u)^{p/2} R_\omega (E + i\epsilon) \chi (H_\omega) \chi_u \|^2_2) dE \quad (4.20)$$

For any $u$ fixed, given a compact subinterval $I \subset J$ and $M > 0$ we set :

$$A_{u,M,I,\epsilon} = \left\{ E \in I : E (\| (X - u)^{p/2} R_\omega (E + i\epsilon) \chi (H_\omega) \chi_u \|^2_2) \leq M \epsilon^{-(\alpha+1)} \right\}.$$  

We have, taking $T = \epsilon^{-1}$ and using [GK3, Lemma 6.3]

$$| I \setminus A_{u,M,I,\epsilon} | \leq \frac{1}{M \epsilon^{-(\alpha+1)}} \int_{\mathbb{R}} E (\| (X - u)^{p/2} R_\omega (E + i\epsilon) \chi (H_\omega) \chi_u \|^2_2) dE \leq \frac{2\pi}{MT^{\alpha+1}} \int_0^\infty e^{-2t/T} E (\| (X - u)^{p/2} e^{-itH_\omega} \chi (H_\omega) \chi_u \|^2_2) dt \leq \frac{\pi}{MT^{\alpha}} \sup_u E (\mathcal{M}_{u,\omega}(p, \chi, T)). \quad (4.21)$$

**Remark 4.1.** Notice that the analogous sets $A_{k,I,M}$ in the proof [GK3, Theorem 2.11] do not work in the non ergodic setting, so we need to consider a family of sets $A_{u,M,I,\epsilon}$, indexed by $u$.

By hypothesis 2.19 we can pick a sequence $T_k \to \infty$ such that for $k$ big enough, we have $\sup_u E (\mathcal{M}_{u,\omega}(p, \chi, T_k)) < C T_k^\alpha$, then for the corresponding sequence $\epsilon_k \to 0^+$ we have

$$| I \setminus A_{u,M,I,\epsilon_k} | \leq \frac{C}{M} \quad (4.22)$$

Notice that this bound is uniform in $u$.

Thus, for an $E \in I$ fixed and $\epsilon_k = T_k^{-1}$, either $E \in A_{u,I,M,\epsilon_k}$ in which case we have,
\[ \mathbb{E}(\|\Gamma_{y,L} R_\omega(E + i\epsilon_k)\mathcal{X}(H_\omega)\chi_u\|) \leq C_{p,p} L_k^{-p/2} \mathbb{E}\left(\| (X - u)^{p/2} R_\omega(E + i\epsilon_k)\mathcal{X}(H_\omega)\chi_u\|_2\right) \]
\[ \leq C_{p,p} L_k^{-p/2} \mathbb{E}\left(\| (X - u)^{p/2} R_\omega(E + i\epsilon_k)\mathcal{X}(H_\omega)\chi_u\|_2^2\right)^{1/2} \]
\[ \leq C_{p,p} L_k^{-p/2} M^{1/2} \epsilon_k^{-(\alpha+1)/2}. \]  
(4.23)

where we write \(L_k = L(I, \epsilon_k)\), or else, \(E \in I \setminus A_{u,M,1,\epsilon_k}\), so by (4.22) there exists \(E_u \in A_{u,I,M,\epsilon_k}\) such that

\[ |E - E_u| \leq \frac{C}{M} \]

and so, by the resolvent identity and the definition of \(A_{u,M,1,\epsilon},\)

\[ \mathbb{E}(\|\Gamma_{y,L} R_\omega(E + i\epsilon_k)\mathcal{X}(H_\omega)\chi_u\|) \leq \mathbb{E}(\|\Gamma_{y,L} R_\omega(E_u + i\epsilon_k)\mathcal{X}(H_\omega)\chi_u\|)
+ |E - E_u| \mathbb{E}(\| R_\omega(E + i\epsilon_k)\| R_\omega(E_u + i\epsilon_k)\|)
\leq C_{p,p} L_k^{-p/2} M^{1/2} \epsilon_k^{-(\alpha+1)/2} + \frac{C}{M^2}. \]
(4.24)

Therefore,

\[ \mathbb{P}\left(\frac{1}{2 L_k^{\theta+\gamma}} < \|\Gamma_{y,L} R_\omega(E + i\epsilon_k)\mathcal{X}(H_\omega)\chi_{y,L_k/\gamma}\|\right) \leq C'_{p,p} L_k^{\theta+\gamma-p/2+d} M^{1/2} \epsilon_k^{-(\alpha+1)}
+ C''_{p,p} L_k^{\theta+\gamma+d} \frac{M^2}{M^2}. \]  
(4.25)

The remaining terms \((4.17)\) and \((4.18)\) are estimated in the same way, using the fact that \(\text{dist}(\Lambda_{L-1} \setminus \Lambda_{L-3}, \Lambda_{2L}) \geq \frac{L}{3} - \frac{3}{2}\) and \(\text{dist}(\Lambda_L, \frac{2L}{3}, \Lambda_{2L}) \geq \frac{L}{6}\). For these terms we obtain an estimate as \((4.25)\) with constants \(C_{p,d}^{(2)}\), \(C_{p,d}^{(2)}\) and \(C_{p,d}^{(3)}\), respectively, and with no \(\theta\) in the exponent of \(L\). Denote by \(C_{p,d}\) the maximal constant, and since \(L^\theta < L^{\theta+\gamma}\), the estimate on \((4.25)\) using \(C_{p,d}\) will imply the same estimate on \((4.17)\) and on \((4.18)\).

Now, for \(p\) such that \(p > p'(\alpha, s) = \alpha \frac{2d}{s} + 12 \frac{d}{s}\), we can find \(\theta, \gamma > d/s\) for which

\[ p > 5\theta + 3\gamma + 2d + (\alpha+1)(\theta s + d)/s, \]  
(4.26)

so if we set

\[ M = L_k^{3\theta+\gamma}, \]  
(4.27)

and recall

\[ \epsilon_k^{-(\alpha+1)/2} = C_{p_0,Q_1} L_k^{(\alpha+1)(\theta s + d)/2s}, \quad \epsilon_k^{-2} = C_{p_0,Q_1} L_k^{-2(\theta s + d)/s}. \]  
(4.28)

we obtain, for \(k\) big enough depending on \(d, I, p, \alpha, \theta, \gamma, s, p_0, Q_1,\)

\[ C_{p,d} L_k^{\theta+\gamma-p/2+d} M^{1/2} \epsilon_k^{-(\alpha+1)} < p_0/24. \]  
(4.29)
and
\[ C''_{p,d} \frac{L_k^{\theta+\gamma+d}}{M^2 L_k} < \frac{p_0}{24}, \quad (4.30) \]
so there exists a sequence \( L_k \to \infty \) such that for \( k \) big enough,
\[ P \left( \frac{1}{2L_k^{\theta+\gamma}} < \| \Gamma_{y,L_k} R_{\omega}(E + i\epsilon_k) \mathcal{X}(H_{\omega}) \chi_{y,L_k/3} \| \right) < \frac{p_0}{12}. \quad (4.31) \]
The same argument shows that the terms (4.17) and (4.18) are smaller than \( \frac{p_0}{12} \), for \( k \) big enough.

Inserting this in (4.16)-(4.18) we see that
\[ \limsup_{k \to \infty} \sup_y P \left( \frac{1}{2L_k^{\theta+\gamma}} < \| \Gamma_{y,L_k} R_{\omega,y,L_k}(E) \chi_{y,L_k/3} \| \right) \leq \frac{p_0}{12}, \quad (4.32) \]
Since \( 0 < \frac{p_0}{12} < 1 \) is arbitrary, we conclude that (4.3) holds for each \( E \in I \).

\[ \Box \]

Proof of Theorem 2.3. From equation (4.3) to equation (4.18) the previous proof remains valid in the current setting. We will only estimate (4.16), since the remaining terms (4.17) and (4.18) can be estimated in the same way. Notice that
\[ P \left( \frac{1}{2L_k^{d/2}} < \| \Gamma_{y,L_k} R_{\omega}(E + i\epsilon_k) \mathcal{X}(H_{\omega}) \chi_{y,L_k/3} \| \right) \]
\[ \leq \sum_{u \in \Lambda_{L/3}(y)} P \left( \frac{1}{2L_k^{\theta+\gamma+d}} < \| \Gamma_{y,L_k} R_{\omega}(E + i\epsilon_k) \mathcal{X}(H_{\omega}) \chi_{u} \| \right) \quad (4.33) \]

To estimate the r.h.s of the last inequality, the following following lemma is crucial,

**Lemma 4.2.** There exists \( \mathcal{L} = \mathcal{L}(I,p,\theta,\gamma,d,\alpha,s,p_0,\epsilon) \) such that for any \( u \in \Lambda_{L/3} \) with \( L = L(I,\epsilon) \) as in (4.12), \( L \geq \mathcal{L} \) and \( E \in I \) fixed, if
\[ p > p(\theta,\gamma,d,\alpha,s) := \alpha \left( \frac{\theta s + d}{s} \right) + 9\theta + 3\gamma + 2d + \frac{d}{s} \quad (4.34) \]
then, for \( T = \epsilon^{-1} \),
\[ \left\{ \omega : \| \Gamma_{y,L_k} R_{\omega}(E + i\epsilon_k) \mathcal{X}(H_{\omega}) \chi_{u} \| > \frac{1}{2L_k^{\theta+\gamma+d}} \right\} \subset \left\{ \omega : \mathcal{M}_{u,\omega}(p,\mathcal{X},T) > T^\alpha \right\}. \]
\[ (4.35) \]

Now, if \( p > p(\alpha,s) := 15\frac{d}{s} + 2\alpha \frac{d}{s} \), then there exist \( \theta,\gamma > d/s \) such that \( p > p(\theta,\gamma,d,\alpha,s) > p(\alpha,s) \) so Lemma 4.2 holds yielding, for \( L = L(I,\epsilon) \) as in (4.12) big enough,
\[ P \left( \frac{1}{2L^{p+\gamma}} < \| \Gamma_{y,L} R_{\omega}(E + i\epsilon) X(H_{\omega}) \chi_{y,L} \| \right) \leq C_{p_0,Q_1} T_k^2 \sup_u P(M_{u,\omega}(p, X, T) > T^\alpha) \]

(4.36)

where \( C_{p_0,Q_1} \) comes from \( L^d = C_{p_0,Q_1} T_k^2 \), by (4.12).

By hypothesis (2.20), we can pick a sequence \( T_k \to \infty \) such that for \( k \) big enough

\[ T_k^2 \sup_u P(M_{u,\omega}(p, X, T_k) > T^\alpha_k) < p_0/12. \]

(4.37)

In an analogous way we can estimate (4.17) and (4.18). It follows that for all \( E \in \mathcal{I} \) we have

\[ \limsup_{k \to \infty} \sup_y P \left( \frac{1}{\Gamma_{y,L} R_{\omega,y,L}(E) \chi_{y,L} / 3} \right) < p_0. \]

(4.38)

Since \( 0 < p_0 < 1 \) is arbitrary, we conclude that (4.3) holds for each \( E \in \mathcal{I} \).

□

Proof of Lemma 4.2. Let \( \omega \in \{ \omega : M_{u,\omega}(p, X, T) \leq T^\alpha \} \). For a given compact subinterval \( I \subset J, M > 0 \) and \( L = L(\epsilon, I) \) as in (4.12), we set

\[ A_{u,\omega,M,I} = \{ E \in I : \| (X - u)^{p/2} R_{\omega}(E + i\epsilon) X(H_{\omega}) \chi_u \|_2^2 \leq M \epsilon^{-(\alpha+1)} \}. \]

We have, using [GK3, Lemma 6.3]

\[ |I \setminus A_{u,\omega,M,I}| \leq \frac{1}{M \epsilon^{-(\alpha+1)}} \int_R \| (X - u)^{p/2} R_{\omega}(E + i\epsilon) X(H_{\omega}) \chi_u \|_2^2 dE \]

\[ = \frac{2\pi}{MT^{\alpha+1}} \int_0^\infty e^{-2t/T} \| (X - u)^{p/2} e^{-iH_{\omega}} X(H_{\omega}) \chi_u \|^2_2 dt \]

\[ = \frac{\pi}{MT^{\alpha}} M_{u,\omega}(p, X, T) \]

\[ \leq \frac{\pi}{M}, \]

(4.39)

where the last bound is uniform on \( u \) and \( \omega \).

Thus, for an \( E \in I \) fixed either \( E \in A_{u,\omega,M,I} \) in which case we have

\[ \| \Gamma_{y,L} R_{\omega}(E + i\epsilon) X(H_{\omega}) \chi_u \| \leq C_{p,d} L^{-p/2} \| (X - u)^{p/2} R_{\omega}(E + i\epsilon) X(H_{\omega}) \chi_u \|_2 \]

\[ \leq C_{p,d} L^{-p/2} M^{1/2} \epsilon^{-(\alpha+1)/2} \]

(4.40)

or else, \( E \in I \setminus A_{u,\omega,M,I} \), so by 4.39 there exists \( E_{u,\omega} \in A_{u,\omega,M,I} \) such that

\[ |E - E_{u,\omega}| \leq \frac{\pi}{M} \]

and therefore, by the resolvent identity and the definition of \( A_{u,\omega,M,I} \).
\[ \| \Gamma_{y,L} R_{\omega} (E + i\epsilon) \chi (H_{\omega}) \chi_u \| \leq \| \Gamma_{y,L} R_{\omega} (E_{u,\omega} + i\epsilon) \chi (H_{\omega}) \chi_u \| \\
+ |E - E_{u,\omega}| \| R_{\omega} (E + i\epsilon) \| \| R_{\omega} (E_{u,\omega} + i\epsilon) \| \\
\leq C_{p,d} L^{-p/2} M^{1/2} \epsilon^{-(\alpha + 1)/2} + \frac{\pi}{Me^2} \tag{4.41} \]

Now, for \( p > p(\theta, \gamma, d, \alpha, s) \) we have
\[ 2(\theta + \gamma + d) < p - 6\theta - \gamma - (1 + \alpha)(\theta s + d)/s \tag{4.42} \]
so if we set
\[ M = L^{6\theta + \gamma}, \tag{4.43} \]
and recall
\[ \epsilon^{-(1+\alpha)/2} = C_{p_0, Q_I} L^{(1+\alpha)(\theta s + d)/2s}, \tag{4.44} \]
we obtain, for \( L \) big enough depending on \( d, I, p, \alpha, \gamma, s, p_0, Q_I \),
\[ C_{p,d} L^{-p/2} M^{1/2} \epsilon^{-(\alpha + 1)/2} = C_{p,d, Q_I, p_0} L^{-p/2 - (6\theta + \gamma)/2 - (1 + \alpha)(\theta s + d)/2s} \]
\[ < \frac{1}{4L^{(\theta + \gamma + d)}} \tag{4.45} \]
and
\[ \frac{\pi}{Me^2} = C'_{p_0, Q_I} L^{6\theta + 2\gamma - 2(\theta s + d)/s} < \frac{1}{4L^{(\theta + \gamma + d)}}. \tag{4.46} \]
Inserting this in (4.41) proves the lemma. \qed

5. **Uniform Wegner estimates for Delone-Anderson type potentials**

**Definition 4.** A subset \( D \) of \( \mathbb{R}^d \) is called an \((r,R)\)-Delone set if there exist reals \( r \) and \( R \) such that for any cubes \( \Lambda_r, \Lambda_R \) of sides \( r \) and \( R \) respectively, we have \( \sharp (D \cap \Lambda_r) \leq 1 \) and \( \sharp (D \cap \Lambda_R) \geq 1 \), where \( \sharp \) stands for cardinality.

**Remark 5.1.** Note that in an \((r,R)\)-Delone set there exists a minimal distance between any two points, \( r/2 \), and a maximal distance between neighbors, \( R/\sqrt{2} \). Such a set is said to be uniformly discrete and relatively dense. A lattice is a particular case of a Delone set.

Take \( 0 < r < R < \infty \) and consider the operator \( H_{\omega} = H_0 + \lambda V_{\omega} \) with random potential given by
\[ V_{\omega}(x) = \sum_{\gamma \in D} \omega_{\gamma} u(x - \gamma), \tag{5.1} \]
where \( D \) is a \((r,R)\)-Delone set. The measurable function \( u \), called single-site potential, is such that \( \| \sum_{\gamma \in D} u(x - \gamma) \|_\infty = 1 \), it has compact support and satisfies
\[ u^- \chi_{0,\epsilon_u} \leq u \leq u^+ \chi_{0,\delta_u}, \tag{5.2} \]
for some constants \( 0 < \epsilon_u \leq \delta_u < \infty \) and \( 0 < u^- \leq u^+ < \infty \).
Here, $(\omega_\gamma)_{\gamma \in D}$ is a family of independent random variables, with probability distributions $\mu_\gamma$ of bounded and continuous densities $\rho_\gamma$ such that

$$\rho_+ := \sup_{\gamma \in D} \|\rho_\gamma\|_\infty < \infty, \quad (5.3)$$

$$0 \in \text{supp } \rho_\gamma \subset [-m_0, M_0] \quad (5.4)$$

where $0 \leq m_0 < \infty$, $0 < M_0 < \infty$. Under these assumptions $V_\omega$ is a bounded scalar potential jointly measurable in both $\omega \in \Omega$ and $x \in \mathbb{R}^d$, and so the mapping $\omega \mapsto H_\omega$ is measurable.

Denote by $H_{\lambda,\omega,x,L}$ and $H_{0,x,L}$ the restriction of $H_\omega$ and $H_0$ to the cube $\Lambda_L(x)$ with periodic boundary conditions, respectively (in the particular case of the Landau Hamiltonian, details on the finite volume operator $H_{B,L}$ are stated in Section 6), with $\lambda$ fixed and $V_{\omega,x,L}$ being the restriction of $V_\omega$ to $\Lambda_L(x)$, defined by

$$V_{\omega,x,L}(\cdot) = \sum_{\gamma \in D \cap \Lambda_L - \delta_u(x)} \omega_\gamma u(\cdot - \gamma), \quad (5.5)$$

and denote by $\tilde{V}_{x,L}$ the potential defined by

$$\tilde{V}_{x,L}(\cdot) = \sum_{\gamma \in \tilde{\Lambda}_L - \delta_u(x)} u(\cdot - \gamma), \quad (5.6)$$

where $\tilde{\Lambda}_L(x) = D \cap \Lambda_L(x)$.

We denote by $P_{\lambda,\omega,x,L}$, $P_{0,x,L}$ the spectral projector associated to the finite volume operators $H_{\lambda,\omega,x,L}$, $H_{0,x,L}$, respectively. In the particular case of the finite volume random Landau Hamiltonian and free Landau Hamiltonian, we write $H_{B,\lambda,\omega,x,L}$ and $H_{B,x,L}$, respectively, and we use the notation $\Pi_{n,x,L}$ for the spectral projector associated to the $n$-th Landau level, and $\Pi^\perp_{n,x,L}$ for its orthogonal projector (see Section 6.1). Define $s(\epsilon) = \sup_{\gamma \in D, E \in \mathbb{R}} \mu_\gamma([E, E + \epsilon])$.

We prove several Wegner estimates that we summarize in the following theorem,

**Theorem 5.1.**

i. For $d = 2$, let $H_0$ be the Landau Hamiltonian with constant magnetic field $B > 0$ fixed. For any bounded interval $I \subset \mathbb{R}$ there exist constants $Q_W = Q_W(B, \lambda, R, r, I, u, m_0, M_0)$, $\eta_{B,\lambda,\Delta} \in [0,1]$ and a finite scale $L_* = L_* (B, \lambda, I, R)$ such that for every compact subinterval $\Delta \subset I$, with $|\Delta| < \eta_{B,\lambda,\Delta}$ and $L > L_*$, we have

$$\sup_{x \in \mathbb{R}^d} \mathbb{E}\{ \text{ tr } P_{\lambda,\omega,x,L}(\Delta) \} \leq Q_W \rho_+ s(|\Delta|) L^d. \quad (5.7)$$

ii. Let $E_0 \in \mathbb{R} \setminus \sigma(H_0)$ for $H_0 = -\Delta + V_0$, where $V_0$ is $\mathbb{Z}^d$-periodic. For any bounded interval $I \subset \mathbb{R} \setminus \sigma(H_0)$ there exist a constant $Q_W = Q_W(\lambda, R, I, u)$ and a finite scale $L_* = L_* (I)$ such that for every compact subinterval $\Delta \subset I$, $\mathbb{E}\{ \text{ tr } P_{\lambda,\omega,x,L}(\Delta) \} \leq Q_W \rho_+ s(|\Delta|) L^d. \quad (5.7)$ holds.
iii. Assume the IDS of $H_0$ is Hölder continuous with exponent $\delta > 0$ in some open interval $I$ and no further assumption on $s(\epsilon)$. Then there exists a constant $Q'_W = Q'_W(B, \lambda, I, u, R, r, d) > 0$ such that for all compact subintervals $\Delta \subset I$ with $|\Delta|$ small enough, and $0 < \gamma < 1$,

$$E\{\text{tr} P_{\lambda, \omega, x, L}(\Delta)\} \leq Q'_W \max\{|\Delta|^{\delta \gamma}, |\Delta|^{-2 \gamma} s(|\Delta|)\} L^d. \quad (5.8)$$

In particular, if $s(\epsilon) \leq C\epsilon^\zeta$, for some $\zeta \in [0, 1]$, then

$$E\{\text{tr} P_{\lambda, \omega, x, L}(\Delta)\} \leq Q'_W |\Delta|^{\frac{\delta \zeta}{2}} L^d. \quad (5.9)$$

Since the results are uniform in $x$, we state them for $x = 0$, $\lambda$ fixed and for simplicity we omit these subscripts from the notation.

For the proof we follow [CHK2], based on [CHK], plus [GKS] in the case of the Landau Hamiltonian. In all cases we need to estimate $E\{\text{tr} P_{\omega, L}(\Delta)\}$. We decompose it with respect to the free spectral projector of an interval $\tilde{\Delta}$, such that $\Delta \subset \tilde{\Delta}$ and $d_\Delta = \text{dist}(\Delta, \Delta^c) > 0$, that is

$$\text{tr} P_{\omega, L}(\Delta) = \text{tr} P_{\omega, L}(\Delta) P_{0, L}(\tilde{\Delta}) + \text{tr} P_{\omega, L}(\Delta) P_{0, L}(\tilde{\Delta}^c). \quad (5.10)$$

The key step in estimating the first term of the r.h.s is to prove a positivity estimate as in [CHK2] Theorem 2.1. In order to obtain this estimate in the case of the Landau Hamiltonian, we need some preliminary lemmas.

**Lemma 5.2.** Using the notations above, there exists a positive finite constant $C_n(B, u, R)$, so that

$$\Pi_{n, L} \tilde{V}_{x, L} \Pi_{n, L} \geq C_n(B, u, R) \Pi_{n, L}. \quad (5.11)$$

**Proof.** From [CHKR] we have that for $n \in \mathbb{N}$, $\tilde{R} > 0$, for each $0 < \epsilon < \tilde{R}$, $\kappa > 1$ and $\eta > 0$ there exists a constant $C_0 = C_{0, n, \epsilon, \tilde{R}, \eta} > 0$ such that

$$\Pi_{n} \chi_{0, \epsilon} \Pi_{n} \geq C_0 (\Pi_{n} \chi_{0, \tilde{R}} \Pi_{n} - \eta \Pi_{n} \chi_{0, \kappa \tilde{R}} \Pi_{n}). \quad (5.12)$$

Because of the invariance of $H_B$ under the magnetic translations $[6.2]$ we have that the projections $\Pi_{n}$ commute with these unitary operators, which in turn gives, for an arbitrary $x \in \mathbb{R}^2$,

$$U_{x} \Pi_{n} \chi_{0, \epsilon} \Pi_{n} U_{x}^* \geq C_0 U_{x} (\Pi_{n} \chi_{0, \tilde{R}} \Pi_{n} - \eta \Pi_{n} \chi_{0, \kappa \tilde{R}} \Pi_{n}) U_{x}^* \quad (5.13)$$

$$\Pi_{n} U_{x} \chi_{0, \epsilon} U_{x}^* \Pi_{n} \geq C_0 (\Pi_{n} U_{x} \chi_{0, \tilde{R}} U_{x}^* \Pi_{n} - \eta \Pi_{n} U_{x} \chi_{0, \kappa \tilde{R}} U_{x}^* \Pi_{n}) \quad (5.14)$$

$$\Pi_{n} \chi_{x, \epsilon} \Pi_{n} \geq C_0 (\Pi_{n} \chi_{x, \tilde{R}} \Pi_{n} - \eta \Pi_{n} \chi_{x, \kappa \tilde{R}} \Pi_{n}), \quad (5.15)$$

since conjugation by unitary operators is a positivity preserving operation.

Now, we recall [GKS] Lemma 5.3] (which is independent of $V$ and, therefore, $D$).

**Lemma 5.3.** Fix $B > 0$, $n \in \mathbb{N}$, $\tilde{R} > 0$, $0 < \epsilon < \tilde{R}$ and $\eta > 0$. If $\kappa > 1$ and $L \in \mathbb{N}_B$ (defined as in [6.8]) are such that $L > 2(L_B + \kappa \tilde{R})$ then for all $\tilde{x} \in \Lambda_L(x)$, we have
\[ \Pi_{n,L} \hat{\chi}_{x,R} \Pi_{n,L} \geq C_0 \Pi_{n,L} (\hat{\chi}_{x,R} - \eta \hat{\chi}_{x,R}) \Pi_{n,L} + \Pi_{n,L} \mathcal{E}_{n,\hat{\chi},L} \Pi_{n,L}, \quad (5.16) \]

where \( C_0 = C_{0,n,B,\epsilon,R,\eta} > 0 \) is a constant as before and the error operator \( \mathcal{E}_{n,\hat{\chi},L} \) satisfies

\[ \| \mathcal{E}_{n,\hat{\chi},L} \| \leq C_{n,B,\epsilon,R,\eta} e^{-m_{n,B} L}, \quad (5.17) \]

for some positive constant \( m_{n,B} \).

Now, by (5.2) we have

\[ \hat{V}_{x,L}(\cdot) = \sum_{\gamma \in \tilde{\Lambda}_{L-s_\omega}} u(\cdot - \gamma) \geq u - \sum_{\gamma \in \tilde{\Lambda}_{L-s_\omega}} \hat{\chi}_{\gamma,\varsigma_\omega}. \quad (5.18) \]

We fix \( \hat{R} > 2R + \delta u \), in which case

\[ \sum_{\gamma \in \tilde{\Lambda}_{L-s_\omega}} \hat{\chi}_{\gamma,\hat{R}} \geq \chi_{x,L}. \quad (5.19) \]

Now fix \( \kappa > 1 \) and pick \( \eta > 0 \) such that

\[ \eta \sum_{\gamma \in \tilde{\Lambda}_{L-s_\omega}} \hat{\chi}_{\gamma,\kappa \hat{R}} \leq \frac{1}{2} \chi_{x,L}. \quad (5.20) \]

It follows from Lemma 5.3, (5.19) and (5.20) that

\[ \Pi_{n,L} \hat{V}_{x,L} \Pi_{n,L} \geq u - C_0 \sum_{\gamma \in \tilde{\Lambda}_{L-s_\omega}} \Pi_{n,L} (\hat{\chi}_{\gamma,\hat{R}} - \eta \hat{\chi}_{\gamma,\kappa \hat{R}}) \Pi_{n,L} + \Pi_{n,L} \mathcal{E}_{n,L} \Pi_{n,L} \]

\[ \geq \frac{u - C_0}{2} \Pi_{n,L} + \Pi_{n,L} \mathcal{E}_{n,L} \Pi_{n,L} \]

\[ \geq C_1 \Pi_{n,L}, \quad (5.21) \]

for \( L \geq L^* \) for some \( L^* = L^{*,n,B,\epsilon,R,\kappa,\eta} < \infty \) and \( C_1 = \frac{u - C_0}{2} \), since the error operator

\[ \Pi_{n,L} \mathcal{E}_{n,L} \Pi_{n,L} = \Pi_{n,L} \sum_{\gamma \in \tilde{\Lambda}_{L-s_\omega}} \mathcal{E}_{n,\gamma,L} \Pi_{n,L} \]

by (5.17), satisfies

\[ \| \mathcal{E}_{n,L} \| \leq L^2 C_{n,B,\epsilon,R,\eta} e^{-m_{n,B} L}. \]

Finally we recall,

**Lemma 5.4.** [CHK2, Lemma 2.1] Suppose that \( T \) is a trace class operator independent of \( \omega \) and \( u \), the single site potential (5.2). We then have

\[ E \{ \text{tr} P_{\omega,L}(\Delta) u_i T u_j \} \leq 8s(\| \Delta \|) \| u_i T u_j \|_1. \quad (5.24) \]

where we use the notation \( u_i = u_\omega(x - i), \ i \in \mathbb{R}^2 \).
Proof of Theorem 5.1. To prove (i), using the preliminary lemmas we can follow the proof in [CHK2, Theorem 4.3]. Notice that the spatial homogeneity of the Delone set in the sense that points do not accumulate neither are too far away, so the sums over indexes of elements of \( D \) preserves the properties of the sums over indexes of elements of the lattice \( \mathbb{Z}^2 \) as the original proofs.

Recall that we need to estimate \( \mathbb{E}\{\text{tr} P_{\omega,L}(\Delta)\} \) as in (5.10), that is, for an arbitrary \( E_0 \in \mathbb{R} \), with \( \Delta \) and \( \tilde{\Delta} \) closed bounded intervals centered on \( E_0 \) such that \( \Delta \subset \tilde{\Delta} \), \( |\Delta| < 1 \), \( d_\Delta > 0 \), we need to estimate

\[
\text{tr} P_{\omega,L}(\Delta) = \text{tr} P_{\omega,L}(\Delta)\Pi_{n,L} + \text{tr} P_{\omega,L}(\Delta)\Pi_{n,L}^\perp.
\]

(5.25)

a. Estimate on \( \mathbb{E}\{\text{tr} P_{\omega,L}(\Delta)\Pi_{n,L}^\perp\} \).

The analysis in [CHK2, Eq. 2.6 - 2.10] for the \( n \)-th Landau band remains valid taking, for the constants defined therein, \( M = 1 \) and the operator \( K \) defined by

\[
K \equiv \left( \frac{H_{B,L} + 1}{H_{B,L} - E_m} \right)^2 \quad \|K\| \leq K_n \equiv \left( 1 + \frac{1 + \Delta_+}{d_n} \right)^2,
\]

(5.26)

where \( E_m \) is an eigenvalue of \( H_{B,\lambda,\omega,L} \), \( d_n \equiv \min\{\text{dist}(I, B_{n-1}), \text{dist}(I, B_{n+1})\} \) and \( \Delta = [\Delta_-, \Delta_+] \).

Then we can obtain the analog of [CHK2, Eq. 4.4],

\[
\text{tr} P_{\omega,L}(\Delta)\Pi_{n,L}^\perp \leq K_n \lambda^2 \max\{m_0, M_0\}^2 \sum_{i,j \in \tilde{\Lambda}} |\text{tr} P_{\omega,L}(\Delta)u_i K_{ij}|,
\]

(5.27)

where \( K_{ij} \equiv \chi_i(H_{B,L} + 1)^{-2}\chi_j \), for \( \chi \geq 0 \) a smooth function of compact support slightly larger than the support of \( u \) such that \( \chi u = u \). Note that due to the spatial homogeneity of \( D \) and the fact that supp \( u \) is contained in a cube of side \( r \), the translated supports of \( u \) do not overlap.

Now, denote by \( \tilde{\Lambda}_0 = \{i, j \in \tilde{\Lambda}/\chi_i \chi_j = 0\} \) and by \( \tilde{\Lambda}_0^c = \{i, j \in \tilde{\Lambda}/\chi_i \chi_j \neq 0\} \). For \( i, j \in \tilde{\Lambda}_0 \), the operator \( K_{ij} \) is trace class [BGKS Lemma 2.2], [CHK2 Lemma 5.1] and it satisfies the Combes-Thomas estimate,

\[
\|K_{ij}\|_1 = \|\chi_i(H_{B,L} + 1)^{-2}\chi_j\|_1 \leq C_0^e e^{-\tilde{C}_0\|i-j\|},
\]

(5.28)

where \( C_0^e \) and \( \tilde{C}_0 \) are positive constants. So we can use Lemma 5.4 to obtain

\[
\mathbb{E}\{\sum_{i,j \in \tilde{\Lambda}_0} \text{tr} P_{\omega,L}(\Delta)u_i K_{ij}\} \leq \mathbb{E}\{\sum_{i,j \in \tilde{\Lambda}_0} |\text{tr} P_{\omega,L}(\Delta)u_i K_{ij}|\} \leq C_08s(|\Delta|) \sum_{i,j \in \tilde{\Lambda}_0} e^{-\tilde{C}_0\|i-j\|} \leq C_1 s(|\Delta|)|\Delta|,
\]

(5.30)

where \( C_1 \) also depends on \( r \), since \( |\tilde{\Lambda}_0| \leq C_{r,d} L^d \) for \( L > R \), see Eq. (6.26).

On the other hand, for \( i, j \in \tilde{\Lambda}_0^c \), \( K_{ij} \) is also trace class [BGKS Lemma 2.2] so we can apply Lemma 5.4 again, obtaining
\[ \mathbb{E}\{\text{tr}P_{\omega,L}(\Delta)\Pi^\bot_{n,L}\} \leq C_2 s(|\Delta|)|\Lambda|, \]  
where \( C_2 > 0 \) depends on \( u, I, \lambda, r \) and \( M = \max\{m_0, M_0\} \).

b. **Estimate on** \( \mathbb{E}\{\text{tr}P_{\omega,L}(\Delta)\Pi_{n,L}\} \).

We use the spectral projector \( \Pi_{n,L} \) in order to control the trace. Here the key ingredient is the positivity estimate (5.11) and the fact that, under our hypotheses on \( u \), there exists a finite constant \( C_u \), depending on \( u \) only, such that
\[ 0 < \tilde{V}_L^2 \leq C_u \tilde{V}_L. \]  
Now,
\[ \text{tr}P_{\omega,L}(\Delta)\Pi_{n,L} \leq \frac{1}{C_n(B, u, R)} \text{tr}P_{\omega,L}(\Delta)\Pi_{n,L}\tilde{V}_L\Pi_{n,L} \]  
\[ \leq \frac{1}{C_n(B, u, R)} \left\{ \text{tr}P_{\omega,L}(\Delta)\tilde{V}_L\Pi_{n,L} - \text{tr}P_{\omega,L}(\Delta)\Pi^\bot_{n,L}\tilde{V}_L\Pi_{n,L} \right\}. \]  
(5.34)

Then we can proceed as in parts (2) and (3) of the proof of [CHK2, Theorem 4.3], and we finally arrive to the desired result,
\[ \mathbb{E}\{\text{tr}P_{\omega,L}(\Delta)\} \leq Q_W s(|\Delta|)|\Lambda|. \]  
where the constant \( Q_W > 0 \) depends on \( B, u, R, I, \lambda \) and \( M \).

As for \((ii)\), note that in this case \( \text{tr}P_{0,L}(\tilde{\Delta}) = 0 \) if \( \tilde{\Delta} \subset \mathbb{R} \setminus \sigma(H_0) \), so we only need to estimate the second term in the r.h.s. of (5.10), where we do not need the positivity estimate (5.11) for \( P_{0,L} \). The proof mimics \((i)-a\).

In case \((iii)\) we can estimate the first term in the r.h.s. of (5.10) without using the analog of (5.11) for \( P_{0,L} \). Instead, the Hölder continuity of the IDS of the non perturbed operator implies that there exists a constant \( C > 0 \) such that
\[ \text{tr}P_{0,L}(\tilde{\Delta}) \leq C|\tilde{\Delta}|^\gamma|\Lambda|, \]  
and so, for \( 0 < \gamma < 1 \)
\[ \text{tr}P_{\omega,L}(\Delta)P_{0,L}(\tilde{\Delta}) \leq C|\Delta|^{\gamma}|\Lambda|. \]  
(5.36)

Since, as in the previous case (writing explicitly the dependence on \( d_\Delta \)) we have
\[ \mathbb{E}\{\text{tr}P_{\omega,L}(\Delta)P_{0,L}(\tilde{\Delta})\} \leq \frac{Q'_W}{d_\Delta} s(|\Delta|)|\Lambda|, \]  
by taking \( d_\Delta = |\Delta|^\gamma \) we obtain the desired result. Furthermore, if \( s(\epsilon) \) is \( \zeta \)-Hölder continuous, we get, taking \( \gamma \) such that \( \gamma \delta = \zeta - 2\gamma \),
\[ \mathbb{E}\{\text{tr}P_{\omega,L}(\Delta)\} \leq Q'_W \max\{|\Delta|^{\delta}, |\Delta|^{\zeta-2\gamma}\}L^2 \]  
\[ \leq Q'_W |\Delta|^{\frac{\zeta}{\delta}}L^2, \]  
(5.38)

where \( Q'_W \) depends on \( u, I, \lambda, R, r \) and \( M \).

\( \Box \)
6. Applications to non ergodic random Landau operators

6.1. The model. We consider the case where the free Hamiltonian in (2.1) is $H_B$, the Landau Hamiltonian, and the random potential represents impurities placed in a Delone set (for the case $H_0 = -\Delta$ see [G]). We aim to prove for this model the existence of complementary regions of dynamical localization and delocalization in the spectrum and therefore, the existence of a dynamical transition energy. By doing this we extend known results for ergodic random Landau Hamiltonians [CH, CH2, GKS, GKS2] to non-ergodic ones.

Let $H_B$ be the unperturbed Landau Hamiltonian on $L^2(\mathbb{R}^2)$

$$H_B = (-i \nabla - A)^2 \quad \text{with} \quad A = \frac{B}{2} (x_2, -x_1),$$

where $A$ is the vector potential and $B$ is the strength of the magnetic field.

The spectrum of $H_B$ is pure point and consists of a sequence of infinitely degenerate eigenvalues, the Landau levels

$$\{B_n = (2n + 1)|B|; \ n = 0, 1, ... \},$$

with associated orthogonal projection operators $\Pi_n$. As the spectrum is independent of the sign of $B$, we will always assume $B > 0$.

We define the magnetic translations $U_a$ for $a \in \mathbb{R}^2$ and $\varphi \in \mathcal{C}_0^\infty(\mathbb{R}^2)$, by

$$U_a \varphi(x) = e^{-i \frac{B}{2} (x_2 a_1 - x_1 a_2)} \varphi(x - a),$$

obtaining a projective unitary representation of $\mathbb{R}^2$ on $L^2(\mathbb{R}^2)$:

$$U_a U_b = e^{i \frac{B}{2} (a_2 b_1 - a_1 b_2)} U_{a+b} = e^{i B (a_2 b_1 - a_1 b_2)} U_b U_a, \quad a, b \in \mathbb{R}^2.$$

We then have $U_a H_B U_a^* = H_B$ for all $a \in \mathbb{R}^2$.

We consider the perturbed family of Landau Hamiltonians given by

$$H_{B, \lambda, \omega} = H_B + \lambda V_\omega \quad \text{on} \quad L^2(\mathbb{R}^2),$$

where, as before, $\lambda$ is the disorder parameter which we consider fix and $V_\omega$ is the Delone-Anderson type potential given by (6.24)-(5.4) with the additional conditions:

(a.c.) $\delta_a < \tilde{r}/10$, i.e. $u$ has compact support contained in $B(0, \tilde{r}/10)$. This implies that for $i, j \in D$ with $i \neq j$, supp $u_i \cap$ supp $u_j = \emptyset$, where we use the notation $u_i = u(\cdot - i)$ for $i \in \mathbb{R}^2$.

(a0.) $\|u\|_\infty = 1$ and $u(0) = 1$.

We denote the spectrum of this operator by $\sigma_{B, \lambda, \omega}$. By perturbation theory [K, Theorem V.4.10] we know that for each $\omega \in \Omega$

$$\sigma_{B, \lambda, \omega} \subset \bigcup_{n=0}^{\infty} B_n(B, \lambda),$$

where $B_n(B, \lambda) = [B_n - \lambda m_\omega, B_n + \lambda M_0]$ is called the $n$-th Landau band. Moreover, by a Borel-Cantelli argument, for almost every $\omega \in \Omega$,

$$\sigma_B \subset \sigma_{B, \lambda, \omega}$$

(6.5)
where $\sigma_B$ is the spectrum of the free Landau operator. We also show that there exists almost surely spectrum near the band edges so our results are not empty (see Section 6.4).

For $B$ fixed $\lambda$ is small enough such that

$$\lambda(m_0 + M_0) < 2B,$$

i.e., the Landau bands $B_n(B, \lambda)$ are disjoint and hence the open intervals

$$G_n(B, \lambda) = [B_n + \lambda M_0, B_{n+1} - \lambda m_0], \quad n = 0, 1, 2, \ldots$$

are nonempty spectral gaps for $H_{B,\lambda,\omega}$.

We now define finite volume operators following [GKS]. For $B > 0$, we set

$$K_B = \min \left\{ k \in \mathbb{N} : k \geq \sqrt{\frac{B}{4\pi}} \right\} \quad \text{and} \quad L_B = K_B \sqrt{\frac{B}{4\pi}}.$$  

We denote $N_B = L_B \mathbb{N}$, $\tilde{N}_B = N_B \cup \{\infty\}$ and $\mathbb{Z}_B^2 = L_B \mathbb{Z}^2$.

We consider squares $\Lambda_L(x)$ with $L \in N_B$ and $x \in \mathbb{R}^2$, and identify them with the torii $T_{L,x} := \mathbb{R}^2 / (L \mathbb{Z}^2 + x)$. We denote by $\chi_{x,L}$ the characteristic function of the cube $\Lambda_L(x)$ and for $\tilde{x} \in \Lambda_L(x)$ and $r < L$ we denote by $\Lambda_{r,\tilde{x}}$ and $\tilde{\chi}_{r,\tilde{x}}$ the cube and characteristic function in $T_{L,x}$.

For the first order differential operator $D_B = (-i \nabla - A)$ restricted to $C^\infty_c(\Lambda_L(x))$ we take its closed, densely defined extension $D_{B,x,L}$ from $L^2(\Lambda_L(x))$ to $L^2(\Lambda_L(x); \mathbb{C}^2)$, with periodic boundary conditions and then set $H_{B,x,L} = D_{B,x,L}^* D_{B,x,L}$.

We are left with the operator $H_{\omega,B,x,L}$ acting on $L^2(\Lambda_L(x))$ defined by

$$H_{B,\lambda,\omega,x,L} = H_{B,x,L} + \lambda V_{\omega,x,L}.$$  

where $V_{\omega,x,L}$ is defined as in 6.24.

We write $R_L(z) = (H_{B,\lambda,\omega,x,L} - z)^{-1}$ for the resolvent operator of $H_{B,\lambda,\omega,x,L}$.

Since $H_{B,x,L}$ has a compact resolvent, its spectrum consists in the Landau Levels but now with finite multiplicity. We denote by $\Pi_{n,L}$ the orthogonal projection associated to the $n$-th Landau level and define $P_{B,\lambda,\omega,x,L}(J) = \chi_J(H_{B,\lambda,\omega,x,L})$ for $J \subset \mathbb{R}$ a Borel set.

This operator satisfies the compatibility conditions [GKS, Eq. 4.2]: If $\varphi \in D(D_{B,x,L})$ with supp $\varphi \subset \Lambda_{L-\delta_{L}}(x)$, then $I_{x,L} \varphi \in D(D_B)$ and

$$I_{x,L} D_{B,x,L} \varphi = D_B I_{x,L} \varphi,$$

$$I_{x,L} \chi_{x,L-\delta_{L}} V_{\omega,x,L} = \chi_{x,L-\delta_{L}} V_{\omega},$$

where $I_{x,L} : L^2(\Lambda_L(x)) \to L^2(\mathbb{R}^2)$ is the canonical injection

$$I_{x,L} \varphi(y) = \begin{cases} 
\varphi(y) & \text{if } y \in \Lambda_L(x) \\
0 & \text{otherwise.}
\end{cases}$$

From this we have

$$I_{x,L} H_{B,\lambda,\omega,x,L} \varphi = H_{B,\lambda,\omega} I_{x,L} \varphi.$$
that is, the finite volume operators $H_{B,\lambda,\omega,x,L}$ agree with $H_{B,\lambda,\omega}$ inside the square $\Lambda_L(x)$.

However, $H_{B,\lambda,\omega,x,L}$ does not satisfy the covariance condition (2.3) so we have a priori

$$H_{B,\lambda,\omega,x,L} \neq U_x H_{B,\lambda,\tau_x(\omega),0,L} U_x^*,$$

where $U_x$ is the magnetic translation (6.2) seen as a unitary map from $L^2(\Lambda_L(0))$ to $L^2(\Lambda_L(x))$ and $\tau_x$ is the translation defined as $\tau_x(\omega) = \omega_{x-g}$ for $x \in \mathbb{R}^2$.

### 6.2. Dynamical localization in Landau bands.

In this section we prove

**Theorem 6.1.** Let $H_\omega$ be as before. For any $n = 0, 1, 2, \ldots$ there exist finite positive constants $B(n)$ and $K_n(\lambda)$ depending only on $n$, $M$, $u$ and $\rho$ such that for all $B \geq B(n)$ we can perform MSA in the intervals

$$\Sigma_{B,n,\lambda,\omega} = \sigma_{B,\lambda,\omega} \cap \{E \in B_n : |E - B_n| \geq K_n(\lambda) \frac{\log B}{B}\}, \quad (6.11)$$

We have strong HS-dynamical localization at energy levels up to a distance $K_n(\lambda) \frac{\log B}{B}$ from the Landau levels for large $B$.

For the proof we need to verify the conditions to start the modified Multiscale Analysis, Theorem 2.1. As mentioned in the proof of Theorem 2.1 this model satisfies properties (IAD), (R), (EDI), (SLI) and (UNE). What is left to prove is the existence of a suitable length scale $L_0$ that satisfies (2.8) and (UWE). The latter comes from the following improvement in the Wegner estimate of the previous section and it follows [CH, Theorem 3.1].

**Theorem 6.2.** There exists $\tilde{B} > 0$ and a constant $Q_n = \tilde{Q}_{n,\lambda,u}\|\rho\|_\infty$ such that for all $B > \tilde{B}$ and for any closed interval $\Delta \subset B_n \setminus \sigma(H_B)$

$$\mathbb{E}\{\text{tr} P_{B,\lambda,\omega,x,L}(\Delta)\} \leq Q_n \frac{B}{2(\text{dist}(\Delta,B_n))^2}|\Delta|L^2. \quad (6.12)$$

In particular, for $E_0 \notin \sigma(H_B)$ and all $0 < \epsilon < |E_0 - B_n|$, we have

$$\mathbb{P}\{\text{dist}(\sigma(H_{B,\lambda,\omega,x,L}),E_0) \leq \epsilon\} \leq Q_n \frac{B}{(|E_0 - B_n| - \epsilon)^2} \epsilon L^2. \quad (6.13)$$

**Proof.** Without loss of generality we work within the first Landau band $B_0$, containing the Landau level $B_0$. Set $M = \|V_\omega\|_\infty = \max\{m_0,M_0\}$. Let $\Delta$ be an interval such that $\Delta \subset B_0 \setminus \{B_0\}$ and inf $\Delta > B$, so dist $(\Delta,B_0) > 0$.

Following the same arguments in [CH, Eq. 3.4 - 3.11], we get

$$\mathbb{E}\{\text{tr} P_L(\Delta)\} < \text{dist}(\Delta,B_0)^{-2}M^2\|\rho\|_\infty|\Delta| \sum_{i,j \in D} \|\Pi_{i,j,L}^{ij}\|_1, \quad (6.14)$$

where $P_L(\Delta)$ stands for $P_{B,\lambda,\omega,x,L}(\Delta)$ and we use the notation $A^{ij} = u_i^{1/2} A u_j^{1/2}$ for any bounded operator $A$.

To evaluate the sum we consider separately the indices $i,j$ for which $||i-j|| < 4\delta_u$ and those for which $||i-j|| \geq 4\delta_u$, with $\delta_u$ as in (5.2).
Let $\chi_{ij}$ be the characteristic function of $\text{supp}(u_i + u_j)$. Again, as in Thm 5.1 the translated supports of $u$ behave in a similar way as in the lattice. Then we follow the same arguments therein and obtain, using [CH Lemma 2.1],

$$
\sum_{|i-j|<4\delta_u} \| \Pi_{0,L}^{ij} \|_1 \leq \| u \|_\infty^2 \sum_{|i-j|<4\delta_u} \| \chi_{ij} \Pi_{0,L} \chi_{ij} \|_1 \leq C_0 B|\Lambda|\text{supp } u, \quad (6.15)
$$

where the constant $C_0$ actually depends on the index $n$ of the Landau level, which in this case is 0.

Define $\chi_{ij}^+$ to be the characteristic function of the set $\{ x \in \mathbb{R}^2 : \|x-i\| < \|x-j\| \}$ and denote $\chi_{ij}^- = 1 - \chi_{ij}^+$. Then we obtain

$$
\| \Pi_{0,L}^{ij} \|_1 \leq \| u_j^{1/2} \Pi_{0,L} \chi_{ij}^{+2} \|_{L^2} \| \chi_{ij}^- \Pi_{0,L} u_i^{1/2} \|_{L^2} + \| u_j^{1/2} \Pi_{0,L} \chi_{ij}^- \|_{L^2} \| \chi_{ij}^- \Pi_{0,L} u_i^{1/2} \|_{L^2}.
$$

Now, if $|i-j| \geq 4\delta_u$, condition (5.2) implies that

$$
\text{dist}(\text{supp } \chi_{ij}^+, \text{supp } u_j) \geq \frac{|i-j|}{2} - \delta_u \geq k|i-j|
$$

for some $k > 0$. Similarly for $\text{dist}(\text{supp } \chi_{ij}^-, \text{supp } u_i)$. We then obtain

$$
\sum_{|i-j|\geq4\delta_u} \| \Pi_{0,L}^{ij} \|_1 \leq C_1 |\text{supp } u|\Lambda. \quad (6.16)
$$

Combining (6.14), (6.15) and (6.16) we obtain

$$
\mathbb{E}\{\text{tr}P_L(\Delta)\} \leq Q_0 (\text{dist}(\Delta, B_0))^{-2} |\rho|\|_\infty^2 \epsilon B|\Lambda|,
$$

where the constant $Q_0$ depends on $\lambda$, $M$, $\|u\|_\infty$ and $\text{supp } u$. Taking $\Delta = [E_0 - \epsilon, E + \epsilon]$ for small $\epsilon > 0$ and applying Chebyshev’s inequality we obtain (6.13). $\square$

As for the initial length scale estimate (2.8) to start the multiscale analysis, we need to verify that for some $L_0 \in 6\mathbb{N}$ sufficiently large (as specified in [GK2]), given $\theta > 0$, $E \in \mathbb{R} \setminus \sigma(B_{B,L})$,

$$
\mathbb{P}\left\{ \| \Gamma_{x,L_0} R_{B,\omega,x,L_0}(E) \chi_{x,L_0/3} \| \leq \frac{1}{L_0^\theta} \right\} > 1 - \frac{1}{L_0^p}, \quad (6.17)
$$

for a suitable choice of $p$, where $\Gamma_{x,L} = \chi_{\Lambda_{L-1}(x) \setminus \Lambda_{L-3}(x)}$.

To do so we follow the approach [CH] to obtain estimates that we will later state as in [GK2]. We need to show that in the annular region between a box of side $L/3$ and $L$, there exists a closed, connected ribbon where the potential $V$ satisfies the condition $|V(x) + B_n - E| > a > 0$, for $E \neq B_n$ with a good probability ([CH Eq. 4.2]). To prove this, Combes and Hislop used bond percolation theory, defining occupied bonds of the lattice as those bonds where the potential satisfies this property. However, in our case there is no need to use percolation theory since this fact is assured by the assumption (6.1) on the single-site potential. More precisely, we will show that there exist ribbons where the potential is zero almost surely.
Let us consider the Voronoi diagram associated to $D$. Since $\Lambda_L = D \cap \Lambda_L$ is a discrete bounded set, we can write $\Lambda_L = \{p_1, \ldots, p_n\}$, $n \in \mathbb{N}$. For each site $p_i$ we consider its Voronoi cell, defined as

$$V(p_i) = \{ x \in \mathbb{R}^2 : \|x - p_i\| \leq \|x - p_j\|, j \neq i, 1 \leq j \leq n\},$$

i.e., the set of points that are closer to $p_i$ than to any other site in $\Lambda_L$. The Voronoi diagram associated to $\Lambda_L$, denoted by $\text{Vor}(\Lambda_L)$ is a subdivision of $\Lambda_L$ into Voronoi cells,

$$\text{Vor}(\Lambda_L) = \bigcup_{1 \leq i \leq n} V(p_i).$$

The edges and vertices of $\text{Vor}(\Lambda_L)$ are polygonal connected lines with the property that the minimal and maximal distances from any site $p_i$ to an edge or vertex are $r/4$ and $R/2\sqrt{2}$, respectively.

Now, take a covering of $\Lambda_L/3$ by a finite collection of Voronoi cells, $V_{\Lambda}$, which is a convex polygon. Its perimeter is a polygonal line $C$ that encloses $\Lambda_L/3$ such that $C \cap D = \emptyset$. Taking $L$ big enough with respect to $R$ we have $C \subset \Lambda_L-3 \setminus \Lambda_L/3$. Moreover, assumption $(uc)$ implies that we can always find a ribbon $R$ associated to $C$, i.e., a set

$$R = \{ x \in \mathbb{R}^2 : \text{dist}(x, C) < \frac{\hat{r}}{4} - \frac{\hat{r}}{10}\},$$

such that $V(x) = 0$ for all $x \in R$ (see Fig. 1).

![Diagram of Voronoi cells and ribbon](image)

**Figure 1.** Ribbon $R$ in the Voronoi diagram associated to $D$. Points represent the support of the Delone-Anderson potential.

Then, condition [CH] Eq. (4.2) holds almost surely, therefore [CH] Corollary 4.1 holds almost surely, and this implies (see [CH] Proposition 5.1, [GK2] Theorem 4.3)

**Theorem 6.3.** Let $E = B_n \pm 2a$ for some $n = 0, 1, 2\ldots$ with $0 < 2a < B$. There exists constants $Y_n, \beta_n > 0$ depending only on $n, M, u, \delta_u$ such that for any $0 < \epsilon \leq a$, $L \in 6\mathbb{N}$ and $Q_n$ as in the previous theorem,
\[ P \left\{ \left\| \Gamma_{x,L} R_{B,\omega,x,L}(E) \chi_{x,L/3} \right\| \leq Y_n \frac{B}{a \epsilon^2} e^{-\beta_n \min(aB,\sqrt{B})} \right\} > 1 - Q_n \frac{B \epsilon}{a^2} L^2. \] (6.18)

Therefore, to satisfy (6.17) we need only to verify the conditions

\[ Y_n \frac{B}{a \epsilon^2} e^{-\beta_n \min(aB,\sqrt{B})} \leq 1 - \frac{\theta_0}{L_0}, \] (6.19)

\[ Q_n \frac{B \epsilon}{a^2} L_0^2 \leq 1 - \frac{\theta_0}{L_0}, \] (6.20)

which can be done in the same way as in the proof of [GK2, Theorem 4.1], yielding Theorem 6.1.

### 6.3. Dynamical delocalization in Landau bands.

**Theorem 6.4.** Under the disjoint bands condition (6.6) the random Landau Hamiltonian \( H_{B,\lambda,\omega} \) exhibits dynamical delocalization in each Landau band \( \mathcal{B}_n(B, \lambda) \), i.e. for all \( n = 1, 2, ... \),

\[ \Xi^{DD} \cap \sigma_{B,\lambda,\omega} \cap \mathcal{B}_n(B, \lambda) \neq \emptyset. \] (6.21)

In particular, there exists at least one energy \( E_{n,\omega}(B, \lambda) \in \mathcal{B}_n(B, \lambda) \) such that for every \( X \in C^{\infty}_c(\mathbb{R}) \) with \( X \equiv 1 \) on some open interval \( J \supset E_{n,\omega}(B, \lambda) \) and \( p > 0 \), we have

\[ M_{B,\lambda}(p, X, T) \geq C_{p,\lambda} T^{\frac{p}{4} - 6}, \] (6.22)

for all \( T \geq 0 \) with \( C_{p,\lambda} > 0 \).

This is a consequence of the quantization of the Hall conductance in each Landau band and the fact that in regions of dynamical localization, the Hall conductance is constant, as proven in [GKS, Section 3]. We recall the main lines of their strategy.

Consider the switch function \( h(t) = \chi_{(-\infty, \infty)}(t) \) and let \( h_j \) denote the multiplication by the function \( h(x_j) \), \( j = 1, 2 \). The Hall conductance is defined as

\[ \sigma_{H,\omega}(B, \lambda, E) = -2\pi i \Theta(P_{B,\lambda,\omega,E}) := \text{tr}\left\{ P_{B,\lambda,\omega,E}[[P_{B,\lambda,\omega,E}, h_1], [P_{B,\lambda,\omega,E}, h_2]] \right\}. \] (6.23)

where \( P_{B,\lambda,\omega,E} := P_{B,\lambda,\omega}((-\infty, E]) \).

Following the proof of [GKS, Lemma 3.2] we see that the Hall conductance is constant in connected components of the dynamical localization region, where property SUDEC is valid, as consequence of Theorem 2.1. On the other hand, it is well known that for \( \lambda = 0 \), \( \sigma_{H,\omega}(B, \lambda, E) = n \) if \( E \in (B_n, B_{n+1}) \) for all \( n = 0, 1, 2, ... \). Under the disjoint bands condition (6.6), if \( E \in \mathcal{G}_n(B, \lambda_s) \) for \( \lambda_s \) and some \( n \in \{0, 1, 2, ...\} \), we can find some \( \lambda_E > \lambda_s \) such that \( E \in \mathcal{G}_n(B, \lambda) \) for all \( \lambda \in (0, \lambda_E] \). That is, the spectral gaps stay open as \( \lambda \) increases. Then we prove along the lines of [GKS, Lemma 3.3] that \( \sigma_{H,\omega}(B, \lambda, E) = n \) if \( E \in \mathcal{G}_n(B, \lambda) \), for all \( [0, \lambda_E] \). As the spectral gaps \( \mathcal{G}_n(B, \lambda) \) are by definition part of the localization region, this implies that the Hall conductance has the same value in different gaps, which is a contradiction. Therefore, we must have \( \Xi^{DD} \cap \sigma_{B,\lambda,\omega} \cap \mathcal{B}_n(B, \lambda) \neq \emptyset \) for every \( \omega \in \Omega \).
By Theorems 6.1 and 6.4 we conclude that there exists a dynamical transition energy in each Landau band as stated in Theorem 6.4.

6.4. Almost sure existence of spectrum near band edges. Since we deal with a non ergodic random operator, previous results on the nature of the spectrum do not hold in this setting. In particular, we cannot use the characterization of the spectra as a union of spectra of periodic operators as in [GKS]. We need a more constructive approach and thus, to go back to the argument used in [CH]. We extend [CH, Theorem 7.1] to a Delone-Anderson potential to make sure that, although the spectrum $\sigma_{B,\lambda,\omega}$ is random, there exists almost surely some part of $\sigma_{B,\lambda,\omega}$ in the region were we can prove dynamical localization, that is, in the spectral band edges.

We explicit the dependence on the $(r, R)$-Delone $D$ set by writing $V^D_\omega$ for the Delone-Anderson potential and $H^D_\omega$ for the corresponding random operator defined by (6.4).

Consider the operator acting on $L^2(\mathbb{R}^2)$, $H^D_\omega = H_B + \lambda V^D_\omega$ where $\lambda > 0$ and $V^D_\omega$ is defined as in (6.24). Recall that

$$V^D_\omega(x) = \sum_{\gamma \in D} \omega_\gamma u_\gamma,$$

where $D$ is an $(r, R)$-Delone set, the random variables $\omega_\gamma$ are i.i.d. with absolute continuous probability density $\mu$, $\text{supp } \mu = [-M, M]$ and $u_\gamma = u(x - \gamma)$. Assume moreover $u \in C^2, \|u\|_\infty = 1$, $\text{supp } u \subset \Lambda_r(0)$ and $u(0) = 1$.

**Theorem 6.5.** Under the disjoint bands conditions, for a random Landau Hamiltonian as stated before and any $n = 0, 1, 2, ...$ there exists a finite positive constant $B(n)$ depending on $n, M, u, \lambda$ and $K_n(\lambda)$ such that for all $B > B(n)$, the intervals $\Sigma_{B,n,\lambda,\omega}$ in Theorem 6.1 are almost surely non empty. More precisely, we prove that there exist finite positive constants $C_n, B(n)$ depending on $n, M, u$ such that for every $B > B(n)$, we have for all $E \in \mathcal{E}_n$,

$$\sigma(H_\omega) \cap [E - \lambda C_n B^{-1/2}, E + \lambda C_n B^{-1/2}] \neq \emptyset$$

(6.25)

For a set $A \in \mathbb{R}^2$ we denote by $\tilde{A}$ the intersection $A \cap D$. Recall that we have, for an arbitrary box $\Lambda_L(x)$ of side $L \in \mathbb{N}$ centered in $x$:

$$C_{R,d} L^d \leq \#(\Lambda_L) = \#(D \cap \Lambda_L) \leq C_{r,d} L^d,$$

(6.26)

where $C_{R,d} = R^{-d}$ and $C_{r,d} = [r^{-d}]$.

Take a sequence $\{x_n\}$ such that $|x_n - x_m| > L$ for every $n, m$ and consider the following sets in the probability space $\Omega$:

$$\Omega^L_\epsilon(x_n) = \{ \omega : |\omega_\gamma - \eta| \leq \epsilon \forall \gamma \in \tilde{\Lambda}_L(x_n) \}$$

and

$$\Omega^L_\epsilon = \bigcap_{N} \bigcup_{n \geq N} \Omega^L_\epsilon(x_n)$$

(6.27)

where $\eta \in [-M, M]$. By the choice of $\{x_n\}$, the events $\Omega^L_\epsilon(x_n)$ and $\Omega^L_\epsilon(x_m)$ are independent for $n \neq m$.

Since the random variables are i.i.d. and (6.26) holds for every box $\Lambda_L(x_n)$, we obtain
\[ \mathbb{P} \left( \Omega^L_n(x_n) \right) = \mathbb{P} \left( |\omega_\gamma - \eta| \leq \epsilon, \forall \gamma \in \Lambda_L(x_n) \right) = \mathbb{P} \left( |\omega_\gamma - \eta| \leq \epsilon \right)^{2 \left( |D \cap \Lambda_L(x_n)| \right)} \]  
\[(6.28) \]
\[
\geq \mathbb{P} \left( |\omega_\gamma - \eta| \leq \epsilon \right)^{C_{r,d} L^d} 
\]
\[
= \mu \left( [\eta - \epsilon, \eta + \epsilon] \right)^{C_{r,d} L^d} 
\]
\[(6.29) \]
\[(6.30) \]
\[
(6.31) \]

Therefore
\[
\sum_n \mathbb{P} \left( \Omega^L_n(x_n) \right) = \infty, 
\]
\[(6.32) \]

which implies that \( \mathbb{P} \left( \Omega^L \right) = 1 \), by the Borel-Cantelli lemma.

Given \( \delta > 0 \), take \( \epsilon = \delta/(rL)^d \). We have shown that for \( \omega \in \Omega^L \), a set of full measure, there exists an infinite sequence \( \{x_n\} \) such that for any \( \eta \in [-M,M] \),
\[
|\omega_\gamma - \eta| < \frac{\delta}{(rL)^d} \quad \text{for all } \gamma \in \Lambda_L(x_n) 
\]
\[(6.33) \]

Fix one of these boxes and call it \( \Lambda_0 \) (so \( \Lambda_0 \) depends on \( \omega \), but this procedure can be done for all \( \omega \in \Omega_0 \), the yielding result being uniform in \( \omega \)).

Without loss of generality, \( \Lambda_0 \) contains 0. Indeed, if \( 0 \notin \Lambda_L(x_n) \) for all \( n \), take \( L > R \) so that \( \Lambda_0 \neq 0 \) and take \( \gamma_0 \in \Lambda_0 \). Consider now the operator
\[
H^{D-\gamma_0}_\omega = H_B + \lambda \sum_{\gamma \in D-\gamma_0} \omega_\gamma u_\gamma
\]
\[(6.34) \]

We have that \( \sigma(H^{D}_\omega) = \sigma(H^{D-\gamma_0}_\omega) \), since, taking a translation \( \tau_{\gamma_0} : \Omega \times D \to \Omega \times (D-\gamma_0) \) defined by \( \tau_{\gamma_0}(\omega_\gamma, \gamma) = (\omega_\gamma, \gamma - \gamma_0) \), that associates the same random variable of a point to its translated, we can see \( H^{D}_\omega \) is unitarily equivalent to \( H^{D-\gamma_0}_\omega \).

Moreover, by what is known for \( H^{D}_\omega \), with full probability there exists a sequence \( \{x_n\} = \{x_n-\gamma_0\} \) such that \((6.33)\) holds. In particular, since the cube \( \Lambda_0 \) is a cube that satisfies \((6.33)\) for \( H^{D}_\omega \), then the cube \( \Lambda_{\gamma_0} = \Lambda_0 - \gamma_0 \) satisfies \((6.33)\) for \( H^{D-\gamma_0}_\omega \).

Define
\[
V_{\gamma_0}(x) = \eta \sum_{\gamma \in \Lambda_{\gamma_0}} u_\gamma. 
\]
\[(6.35) \]

Since \( \gamma_0 \in \Lambda_0 = \Lambda_0 \cap D \) we have that \( 0 \in \Lambda_{\gamma_0} = (\Lambda_0 - \gamma_0) \cap (D - \gamma_0) \). Moreover, the assumptions on \( u \), namely that \( u(0) = 1 \) and the supports of \( u_\gamma \) do not overlap, imply that \( V_{\gamma_0}(0) = \eta \). Therefore, without loss of generality we can assume \( \Lambda_0 \) is centered in 0 and so we work from now on with \( H^{D}_\omega, V^{D}_\omega \) and \( V_0 \) as in \((6.35)\) with \( \gamma_0 = 0 \).

**Remark 6.1.** The assumption \( u(0) = 1 \) is so we can later perform a Taylor expansion around 0.

**Proof of Theorem ??**. From now on \( L \) is fixed. For the sake of completeness, we will reproduce the details of [CH Appendix 2] with the corresponding adaptations and work in the 0-th Landau band. Let \( \Pi_0 \) be the Landau projection in the 0-th Landau band, around the Landau level \( B_0 \). Take the normalized function \( \phi_0 \in \Pi_0(H) \), defined by
Anderson metal-insulator transition for non ergodic operators

\[ \phi_0(x) = \left( \frac{2B}{\pi} \right)^{1/2} e^{-B|x|^2}. \] (6.36)

Let \( E \in [B_0 - \lambda M, B_0 + \lambda M] \), that is, \( E = B_0 + \lambda \eta \) for some \( \eta \in [-M, M] \). The case \( \eta = 0 \) is trivial by the previous Borel-Cantelli argument, as \( \{ B_n \}_{n \geq 0} \subset \sigma(H_\omega) \) almost surely. Since the argument is analog for \( \eta < 0 \), in the following we consider only \( \eta \in (0, M] \), and write

\[ \| (H_D^\omega - E) \phi_0 \| = \| (H_D^\omega - B_0 - \lambda \eta) \phi_0 \| \] (6.37)

\[ \leq \| \Pi_0(\lambda V_\omega^\gamma - \lambda \eta) \phi_0 \| + \lambda \| (1 - \Pi_0) V_\omega^D \phi_0 \| \] (6.38)

For simplicity we write \( V_\omega \) instead of \( V_D^\omega \). The deterministic result [CH, Lemma A.1] implies that

\[ \lambda \| (1 - \Pi_0) V_\omega \phi_0 \| \leq \lambda C_1 B^{-1/2}, \] (6.39)

where \( C_1 \) is a constant depending only on the single-site potential \( u \). We are left with

\[ \| \Pi_0(\lambda V_\omega^\gamma - \lambda \eta) \phi_0 \| \leq \lambda \| \left( \sum_{\gamma \in \Lambda_0} \omega_\gamma u_\gamma + \sum_{\gamma \in D \setminus \Lambda_0} \omega_\gamma u_\gamma - \eta \right) \phi_0 \| \] (6.40)

\[ \leq \lambda \| \left( \sum_{\gamma \in \Lambda_0} \omega_\gamma u_\gamma - \eta \right) \phi_0 \| + \lambda \| \sum_{\gamma \in D \setminus \Lambda_0} \omega_\gamma u_\gamma \phi_0 \| \] (6.41)

\[ \leq \lambda \| \left( \sum_{\gamma \in \Lambda_0} \omega_\gamma u_\gamma - \eta \right) \phi_0 \| + \lambda M \sum_{\gamma \in D \setminus \Lambda_0} \| u_\gamma \phi_0 \| \] (6.42)

Recall that

\[ \{ \gamma \in D : \gamma \in D \setminus \Lambda_0 \} \subset \{ \gamma \in D : |\gamma| > r \}. \] (6.43)

The second term in (6.42) can be estimated as in [CH, Eq. 7.6], where it is shown that

\[ \| u_\gamma \phi_0 \|^2 = \int_{\mathbb{R}^2} \phi_0(x)^2 u(x-j)^2 dx \leq \| u \|^2_{\infty} e^{-2B|j|^2 + 4Br|j|} \] (6.44)

which is summable for \( \gamma \) such that \( |\gamma| > r \), yielding that for all \( B > B_* \), for a constant \( B_* \) big enough,

\[ \lambda M \sum_{\gamma \in D \setminus \Lambda_0} \| u_\gamma \phi_0 \| \leq \lambda C_2 B^{-1/2} \] (6.45)

where the constant is uniform in \( B \).

As for the first term in (6.42), recalling the definition of \( V_0 \) from (6.35), we write
\[
\lambda \| \sum_{\gamma \in \Lambda_0} \omega_{\gamma} u_{\gamma} - \eta \|_0 = \lambda \| \sum_{\gamma \in \Lambda_0} \omega_{\gamma} u_{\gamma} - V_0 + V_0 - \eta \|_0 \quad (6.46)
\]

\[
\leq \lambda \| \sum_{\gamma \in \Lambda_0} \omega_{\gamma} u_{\gamma} - \eta \|_0 + \lambda \| V_0 - \eta \|_0 \quad (6.47)
\]

\[
\leq \lambda \| \sum_{\gamma \in \Lambda_0} (\omega_{\gamma} - \eta) u_{\gamma} \phi_0 \phi_0 \| + \lambda \| V_0 - \eta \|_0 \quad (6.48)
\]

By the choice of \(\Lambda_0\) the first term in (6.48) is
\[
\lambda \| \sum_{\gamma \in \Lambda_0} (\omega_{\gamma} - \eta) u_{\gamma} \phi_0 \| \leq \lambda \delta \quad (6.49)
\]

As for the second term in (6.48)
\[
\| (V_0 - \eta) \phi_0 \|_0^2 = \left( \frac{2}{\pi} \right) \int_{\mathbb{R}^2} |V_0(x) - \eta| e^{-2B|x|^2} \, dx \quad (6.50)
\]

\[
= \left( \frac{2}{\pi} \right) \int_{\mathbb{R}^2} |V_0(B^{-1/2}x) - \eta| e^{-2|x|^2} \, dx \quad (6.51)
\]

Now, since \(V_0(0) = \eta\), we have
\[
|V_0(B^{-1/2}x) - \eta| = |V_0(B^{-1/2}x) - V_0(0)| \quad (6.52)
\]

and we can perform a Taylor expansion around 0 for \(V_0\), obtaining, since \(\text{supp } V_0 \subset \Lambda_0\)
\[
|V_0(B^{-1/2}x) - V_0(0)| \leq B^{-1/2} \| x \| \| \nabla V_0 \|_\infty \leq B^{-1/2} L \| \nabla V_0 \|_\infty \quad (6.53)
\]

Notice that \(\| \nabla V_0 \|_\infty \leq C_3\) for a constant \(C_3\) depending only on \(u\), uniformly with respect to \(\eta \in [0, M]\). Replacing this in the integral we obtain
\[
\| (V_0 - \eta) \phi_0 \|_0^2 = \left( \frac{C_4}{\pi B} \right) \int e^{-2 \| x \|^2} \, dx \quad (6.54)
\]

So we obtain more
\[
\lambda \| (V_0 - \eta) \phi_0 \|_0 \leq \lambda C_5 B^{-1/2} \quad (6.55)
\]

Finally, adding the estimates (6.39), (6.45), (6.49) and (6.55) yields that for all \(B > B_*\),
\[
\| H_\omega^D - (B_0 + \lambda \eta) \| \leq \lambda C_5 B^{-1/2} + \delta \quad (6.56)
\]

where the bound is uniform in \(B, \omega \in \Omega_0\) and in \(\eta \in [0, M]\). The same result holds in any Landau band for all \(B\) large enough. Therefore, with probability one and for any \(E = B_0 + \lambda \eta\), we have
\[
\sigma(H_\omega^D) \cap [E - \lambda C_5 B^{-1/2} - \delta, E + \lambda C_5 B^{-1/2} + \delta] \neq 0 \quad (6.57)
\]

Since \(\delta > 0\) is arbitrary,
\[
\sigma(H_\omega^D) \cap [E - \lambda C_5 B^{-1/2}, E + \lambda C_5 B^{-1/2}] \neq 0, \quad (6.58)
\]

for every \(E \in [B_n, B_n + \lambda M]\). This proves that any gap in the spectrum of \(H_\omega^D\) in the Landau band cannot exceed a length of order \(B^{-1/2}\). \(\Box\)
In particular, since we know by perturbation theory that
$$\sigma(H^D) \subset [B_n - \lambda M, B_n + \lambda M],$$
we have that for $E = B_n + \lambda M$, that is, in the edge of the Landau band,

$$\sigma(H^D \omega) \cap [B_n + \lambda M - \lambda C_5 B^{-1/2}, B_n + \lambda M] \neq \emptyset \quad (6.59)$$

On the other hand, by Theorem 6.1 we know the localization region is at a
distance $K_n(\lambda)\ln B$ from the Landau level $B_n$. If $\lambda$ is fixed and $B$ is such that

$$K_n(\lambda)\ln B < \lambda M - \lambda C_n B^{-1/2} \quad (6.60)$$

then the region of the spectrum that is almost surely near the band edge, that is
above $B_n + \lambda M - \lambda C_n B^{-1/2}$, lies in the localization region, that is above $B_n + K_n(\lambda)\ln B$. So we have shown Theorem 6.5, that is, for every $n = 0, 1, 2, \ldots$

$$\Sigma_{B,n,\lambda,\omega} \neq \emptyset \quad \text{for a.e. } \omega \in \Omega \quad (6.61)$$
