Proteomics of stress responses in wheat and barley—search for potential protein markers of stress tolerance

Klára Kosová*, Pavel Vítámvás and Ilja T. Prášil

Laboratory of Plant Stress Biology and Biotechnology, Division of Crop Genetics and Breeding, Department of Plant Genetics, Breeding and Product Quality, Crop Research Institute, Prague, Czech Republic

INTRODUCTION

Wheat (Triticum aestivum; T. durum) and barley (Hordeum vulgare) represent major cereal crops grown in temperate climate areas. Cereal agricultural production is limited by a wide array of abiotic and biotic stress factors including drought (Cattivelli et al., 2008), cold (Thomashow, 1999; Kosová et al., 2008a), heat, salinity (Munns, 2005; Kosová et al., 2013a), imbalances in mineral nutrition, viral (Kosová et al., 2008b) and fungal pathogens such as Fusarium (Kosová et al., 2009; Yang et al., 2010a,b), leaf rust (Puccinia triticina; Rampitsch et al., 2006), blotch (Septoria tritici; Yang et al., 2013) and others, often acting in combinations under field conditions (Mittler, 2006). Proteome plays an important role in stress response since proteins are directly involved in several processes aimed at an enhancement of stress tolerance being “closer to phenotype” than transcripts.

During the past decades, the boom of high-throughput proteomics techniques has enabled the researchers to study plant proteome responses to various factors including stresses in a complex way. Despite numerous studies reporting identifications of a few thousand of proteins in plant samples, a complete description of plant proteome in a given tissue, developmental phase and environmental conditions still remains a great challenge (Jorrin-Novò et al., 2009).

Both abiotic and biotic stresses induce profound changes in plant proteomes aimed at an adjustment of metabolism to altered environment and an enhancement of plant stress tolerance. Plant stress response is a dynamic process and several phases with a unique proteome composition could be distinguished (Levitt, 1980; Larcher, 2003). Reviews on plant proteome responses to abiotic stresses (Kosová et al., 2011; Hossain et al., 2012) and pathogens (Sergeant and Renaut, 2010; Gonzalez-Fernandez and Jorrin-Novò, 2012) provide important overviews; however, several novel studies were published recently (Table 1).

Most proteomic papers aimed at an investigation of plant stress responses are comparative studies that are based on comparison of proteome composition in stressed plants vs. control ones, and also in differentially-tolerant genotypes exposed to stress. Moreover, studies on the roles of subcellular proteomes such as chloroplast (Kamal et al., 2012) and mitochondrial (Jacoby et al., 2010, 2013) proteomes as well as posttranslational modifications (PTMs) such as phosphoproteomics (Yang et al., 2013; Zhang et al., 2014) in wheat exposed to stress have been published recently. Considering the increasing amount of proteomic data, it is arising necessary to mine the data published in various proteomic studies in order to identify key proteins involved in plant responses to a wide array of stress factors (dehydrative stresses—drought, osmotic stress, salinity, frost, heat) as well as proteins induced only at specific stress conditions (e.g., phytochelatins and heavy metal stress). An attempt has already been published regarding proteomic studies under salinity (Zhang et al., 2012). Moreover, comparison of proteome responses in

Keywords: proteome, barley, wheat, abiotic stress factors, biotic stress factors, protein markers
Table 1 | A list of proteomic studies focused on abiotic and biotic stress responses in wheat (*Triticum aestivum; T. durum*), barley (*Hordeum vulgare*), and related species.

|----------------|-----------|---------|---------------------------------------------|------------|
| **LOW TEMPERATURE (COLD, FROST)** | | | | |
| Winter wheats [*Triticum aestivum*] Mironovskaya 808 (T) and Bezostaya 1 (t)–leaf | 2°C (21 days) | 0.1 M Tris-HCl, pH 9; 2DE LC-MS/MS | Up: WCS120, WCS19, COR14a–higher levels in T | Vitámvás et al., 2007 |
| Winter wheats Norstar (T) and Azar2 (t)–leaf | 2°C (0, 14, 26, 42, 56 days) | 2DE MALDI-TOF/TOF | Up: COR/LEA (WCOR14a, WRAB17, WRAB18); Cu/Zn-SOD, 2-2-Cys Prx, GST–higher levels in T | Sarhadi et al., 2010 |
| Winter wheat Cheyenne (T)–leaf | 4°C (63 days) | TCA/acetone; 2DE MS/MS | Up: WCOR18, WRAB17 WCOR615; VER2, glycine-rich RNA binding protein | Rinalducci et al., 2011a |
| Spring wheat Kohdasht (S)–leaf | 4°C (42 days) Control: 20°C (42 days) | TCA/acetone; 2DE MS/MS | Up: APX, DHAR, COR/LEA, cysteine proteinase, proteasome subunit α Down: glycolysis (GAPDH, TPI), Krebs cycle enzymes (MDH), ATP synthase β, ε; PSII subunits | Rinalducci et al., 2011b |
| Winter wheats Mironovskaya 808 (T) and Bezostaya 1 (t)–crown | 6°C (0, 3, 21, 84 days) | TCA/acetone/phenol; 2D-DIGE MALDI-TOF/TOF | 298 DAP (202 identified) Up: 3-PGK, TPI, PGM, ENO; HSP70; MDAR, DHAR, GPX, GST Down: ALDO, GAPDH; SUS1, UDP-glucose pyrophosphorylase; 14-3-3; HSP90; APX Vernalization: Chopper chaperone Genotypic differences: MDH, legumin-like protein–higher in T than t | Vitámvás et al., 2012 |
| Winter wheat Samanta (T), spring wheat Sandra (S)–crown | 4°C (0, 3, 21 days) | TCA/acetone/phenol; 2D-DIGE MALDI-TOF/TOF | 58 DAP (36 identified) Up: GAPDH, β subunit ATP synthase, CPN60α, CPN60β Down: FRK-2, SUS1, 11S seed storage protein Genotypic differences: methionine synthase, elf3, elf5A2–higher in T; VER2, sGRP–higher in S | Kosová et al., 2013b |
| Winter wheats–Shixin 828 (T), Shiluan 02-1 (t)–leaf | −8°C (5 h) | TCA/acetone; 2DE MALDI-TOF/TOF | Rubisco LSU and SSU; α and β subunit ATP synthase, V-ATPase; MDH; Genotypic differences: Rubisco LSU and SSU, PRK; Mn-SOD–higher in T than t | Xu et al., 2013 |
| Wild wheat [*Triticum urartu*]–leaf | 4–6°C (28 days) followed by −2°C (12 h) | TCA/acetone; 2DE MALDI-TOF/TOF | 34 identified proteins–25 up- and 9 down-regulated Up: LEA-III, WCOR14, PR4; OEE1, chloroplastic ribosomal protein L12 Down: Rubisco SSU | Gharechahi et al., 2014 |
| Barley (*Hordeum vulgare*) Winter barley Luxor (T)–crown, leaf | 3°C (0, 1, 21 days), −3°C (1 day) | TCA/acetone/phenol; 2D-DIGE MALDI-TOF | Up: HSP70; OEE1 (PsbO), Down: eEF-Tu; GS1 and 2; UDP-glucose 6-dehydrogenase Both leaf and crown: AAA ATPase, | Hlaváčková et al., 2013 |

|----------------|-----------|---------|---------------------------------------------|------------|
| **HEAT** | | | | |
| Common wheat–Fang (T), Wyuna (S)–grain endosperm | 40/25°C (day/night)–15, 16, 17 days post-anthesis | TCA/acetone 2DE MALDI-TOF; MS/MS Q-TOF | Genotypic differences: Seven small HSP (16.9 kD class I HSP) proteins unique to T | Skylas et al., 2002 |
| Common wheat–Thésée–grain endosperm | 34/10°C (day/night)–697 and 763°C d (degree–days) | Sodium-phosphate buffer; 2 DE MALDI-TOF | 42 identified proteins Up: 20 kD sHSP, 17 kD class II HSP; HSP82 (HSP90 family); eEF-Tu, V-ATPase subunit E Down: starch biosynthesis enzymes granule-bound starch synthase, glucose-1-phosphate adenytransferase; β-amylase; β subunit ATP synthase | Majoul et al., 2004 |
| **DROUGHT** | | | | |
| Common wheat–spring wheats Arvand, Khazar-1, Kelk Afghani–grain endosperm | Field conditions (Azarbayjan) plus artificial irrigation | 2DE MALDI-TOF/TOF | 121 (57 identified) Up: Trx h, 1-Cys peroxiredoxin, GST; PDI; LEA, sHSP71, HSP70 | Hajheidari et al., 2007 |
| Australian wheats Kukri (S), Excalibur, RAC875 (T)–leaf | Water withholding until leaf wilting in Kukri (S)–14, 24 days, and rewatering (25 days) | TCA; nanoLC-MS/MS iTRAQ 8plex | 1299 identified proteins Increase in ROS metabolism-associated proteins (CAT, Cu/Zn-SOD, Mn-SOD), decrease in photosynthesis and Calvin cycle-related proteins (RubisCO; PSI subunit VII PsaC) Genotypic differences: COR410–higher increase in T than S | Ford et al., 2011 |
| Common wheat cv. Nesser (T), Opata M85 (S)–root | 21°C; 40 % humidity–combined effect of drought and ABA (100 μM) | nanoLC-MS/MS iTRAQ | 1656 identified proteins 805 ABA-responsive proteins: LEA, protein phosphatases PP2C; Genotypic differences: HSP70, HSP90; 14-3-3, G-proteins; V-ATPase–higher in T; β-expansin, porins–higher in S | Alvarez et al., 2014 |
| Durum wheat cv. Ofanto–leaf | 70 % FWC for 7 days (control); 57 % FWC for 7 days (stress) | 175 mM Tris-HCl, pH 8.8, TCA-acetone; 2DE MALDI-TOF | 36 identified proteins Up: carbonic anhydrase, RubisCO LSU Down: RubisCO SSU, Calvin cycle enzymes (ALDO, PRK); ATP synthase CF1 α; plastidic GS2a,b,c | Caruso et al., 2009 |
| Durum wheat cv. Kiziltan (S), emmer (T. dicoccoides) lines TR39477, TTD22 (T)–leaf | 9 days without watering | 2DE nanoLC-ESI-MS/MS | 76 identified proteins, 11 candidates for drought tolerance Genotypic differences: TPI, ATP synthase CF1 (efficient carbohydrate metabolism and ATP production)–higher in T; β-1,3-glucanase, β-1,4-glucanase, XET (cell wall remodeling for osmotic adjustment and energy source); methionine synthase–higher in S | Budak et al., 2013 |
### Table 1 | Continued

| Plant material | Treatment | Methods | Major differentially-abundant proteins (DAP) | References |
|----------------|-----------|---------|---------------------------------------------|------------|
| Barley cv. Basrah (T) and Golden Promise (S)–leaf, root | 7 days without watering; Control: 80 % RWC; Drought: 70 % RWC (T), 60 % RWC (S) | 10 mM PBS, TCA-acetone; 2D-DIGE MALDI-TOF | Identified proteins: 24 (leaf), 45 (root) Up: ABA-induced protein r40c1, small G-protein Rab2, Myb-like protein, 14-3-3 protein Down: GST, GPX Genotypic differences: Enhanced regulation of ROS (APX, CAT, LOX, class III POX) and protein folding in T than in S | Wendelboe-Nelson and Morris, 2012 |
| Barley–8 Egyptian accessions, 2 selected for proteome analysis 15141 (T), 15163 (S)–leaf | 24°C; 70 % FWC (control); 5 days at 10 % FWC (stress) | TCA/acetone; 2D-DIGE MALDI-TOF | Up: PDI, Hsp90, Hsp100 (Clp protease), chloroplastic ATP synthase CF1 α; Genotypic differences: PPDK, Hsp70, zinc metalloprotease–higher in T than S; proteins involved in osmolyte biosynthesis (betaine aldehyde dehydrogenase, methionine synthase, SUS1)–higher in S than T | Ashoub et al., 2013 |
| Barley cv. Golden Promise–leaf | Ca 100% FWC (control); 25 % FWC (stress)–28 days–combined effect of drought and *Pinformospora indica* | TCA/acetone; 2DE MALDI-TOF/TOF | 45 identified proteins Up: RubisCO activase A, RubisCO SSU, CCOMT Down: PRK, ACP Effect of *P. indica*: RubisCO SSU, PSI Fe-S center, chl a/b binding protein; CCOMT, APX, 30S ribosomal protein 3, V-ATPase, 2-Cys Prx–higher in inoculated than control plants under stress | Ghabooli et al., 2013 |
| OSMOTIC STRESS (PEG-6000) | Common wheat cv. Yumai 34–leaf | Hoagland solution, 15% PEG-6000 (3 days); 0.5 mM SA pretreatment (3 days) | TCA/acetone; 2DE MALDI-TOF/TOF | 82 (76 identified proteins), of which 35 SA-responsive proteins Up: 14-3-3; APX, GST, SA-responsive proteins: GS1c, GST1, PDI; ATP synthase CF1 α, β | Kang et al., 2012 |
| Common wheat–spring wheats Abbondanza (T), Qingchun 38 (S)–leaf | PEG-6000 (−1 MPa; 72 h), recovery (24 h) | TCA/acetone; 2DE MALDI-TOF/TOF | 38 (35 identified proteins) Up: GAPDH B; 26S proteasome, V-ATPase A Down: RubisCO LSU and SSU, GAPDH, TPI, AGPase (starch biosynthesis) Genotypic differences: Less PEG-affected proteins in T than S | Ye et al., 2013 |
| Common wheat cv. Hanxuan 10 (T) and Ningchun 47 (t)–seedling leaf | Hoagland solution, 20% PEG-6000 (−075 MPa) for 48 h | TCA/acetone/phenol; phosphopeptide enrichment via TiO₂ microcolumns; LC-MS/MS | 173 (T) and 251 (t) phosphoproteins identified Phosphoproteins identified: signaling (SnRK2 kinase, protein phosphatase 2C, CDPK, calmodulin 2-2); transport (AQP MSSP2; H⁺-ATPase); LEA proteins (WCOR719, WCOR825, WRAB17) | Zhang et al. (2014) |

| **SALINITY**  |           |         |                                             |            |
| Common wheat (\textit{T. aestivum}) Jinan 177 (S), \textit{T. aestivum} × \textit{Thinopyrum ponticum} Shanrong 3 (T)—seedling root | \(\frac{1}{2}\) Hoagland solution, 200 mM NaCl (24 h) | TCA/acetone; 2DE MALDI-TOF; MALDI-TOF/TOF | 114 (110 identified—49 salt-responsive, 34 genotypic differences) Up: 14-3-3; Down: tubulin α-3 Genotypic differences: DEAD-box RNA helicase, DWARF3 (GA biosynthesis), elf5A2, V-ATPase subunit E—higher in T; G-protein β subunit, ethylene receptor ETR1—higher in S | Wang et al., 2008 |
| Common wheat cv. Calingri, Janz (S), Wyalkatchem (T)—shoot mitochondrial fraction | 200 mM NaCl (increase per 50 mM NaCl/days) | Isolation: PVP gradient; acetone extraction; 2D-DIGE LC-MS/MS | 192 DAP (68 identified) Up: AOX, Mn-SOD, VDAC Down: CS, NDPK, outer mitochondrial membrane porin Genotypic differences: AOX, Mn-SOD—higher in T | Jacoby et al., 2010 |
| Common wheat cv. Keumgang—leaf chloroplast fraction | 150 mM NaCl (1, 2, 3 days) | Isolation: Percoll gradient; TCA/acetone; 2D LTO-FTICR-MS | 100 DAP (65 identified) Up: Rubisco, GAPDH, GDH, PDX1.2 and PDX1.3 Down: ATP synthase α, β, γ; V-type proton ATPase | Kamal et al., 2012 |
| Common wheat (\textit{T. aestivum}) cv. Chinese Spring (S), \textit{T. aestivum} × \textit{Lophopyrum elongatum} amphiploid (T)—mitochondrial fraction (shoot, root) | 200 mM NaCl (increase per 50 mM NaCl/days) | 100% acetone (leaf), TCA/acetone (root); 2D-DIGE MALDI-TOF/TOF; HPLC Q-TOF MS/MS (peptide fingerprinting—genotypic differences) | 55 root, 15 shoot differentially abundant proteins Organ-specific differences: aspartate aminotransferase, GDH (up in shoot, down in root) Genotypic differences: Mn-SOD, MDH, aconitase, SHMT, β-CAS—higher in T | Jacoby et al., 2013 |
| Durum wheat (\textit{T. durum}) cv. Ofanto—leaf | 100 mM NaCl (2 days) | TCA/acetone 2DE MALDI-TOF | 38 identified proteins Up (28): TP; CPN60-4, Rubisco activase, carbonic anhydrase; osmolyte biosynthesis-related enzymes (glycine dehydrogenase, SAMs); COR; Cu/Zn-SOD Down (10): ALDO, PGK, Rubisco SSU, OEE1 precursor, β-glucosidase, ATP synthase CF1 α | Caruso et al., 2008 |
| Durum wheat cv. Waha—seed embryo and surrounding tissue | 250 mM NaCl (42 h)—AsA priming (0.5 mM) | KCl (100 mM), acetone/nanoHPLC-MS | 697 identified proteins—proteins involved in energy metabolism, protein metabolism, disease/defense, protein destination, storage—a positive effect of AsA priming on mitigation of salinity stress | Fercha et al., 2013, 2014 |
| Barley cv. OUK305 (T), OU1743 (S)—root | 200 mM NaCl (5 days) | 40 mM Tris, 8 M urea, 4% CHAPS, 0.2% Bio-Lyte; 2DE nanoLC-ESI-MS/MS | 6 differentially abundant proteins CCOMT, DHAR, GST (2 spots), POX, PR10—higher in T than S | Sugimoto and Takeda, 2009 |
Table 1 | Continued

| Plant material | Treatment | Methods | Major differentially-abundant proteins (DAP) | References |
|----------------|-----------|---------|---------------------------------------------|------------|
| Barley cv. Morex (T), Steptoe (S)–root | 100, 150 mM NaCl (13 days) | TCA/acetone; 2DE MALDI-TOF; nanoLC-ESI-Q-TOF MS/MS | 39 differentially abundant proteins Up: LOX1, POX, SAMS, β-1,3-glucanase Down: IDI1, IDI2, IDS2, IDS3, Genotypic differences: class III POX, SAMS–higher in T; APX, MDAR–higher in S | Witzel et al., 2009 |
| Barley cv. Afzal (T), L527 (S)–leaf | 300 mM NaCl (increase per 50 mM NaCl/days)–21 days | TCA/acetone; 2DE MALDI-TOF/TOF | 117 DAP (22 identified proteins) Up:, PC, OEE2, PSI subunit VII (PsaC), PRK; 2-Cys Prx, Trx, GST, SOD; TPI, FBP ALDO–higher in T than S | Rasoulnia et al., 2011 |
| Barley cv. Afzal (T), L527 (S)–leaf | 300 mM NaCl (increase per 50 mM NaCl/days)–24 h | TCA/acetone; 2DE MALDI-TOF/TOF | 44 DAP Up (43): RubisCO LSU, SSU, RubisCO activase, OEE2; NDPK; GLP; profilin; ribosomal protein L12, 30S ribosomal protein S1; translationally-controlled tumor protein homolog Genotypic differences: DHAR, Trx–higher in S | Fatehi et al., 2012 |
| Barley cv. Morex (T), Steptoe (S)–root | 100, 150 mM NaCl (0, 1, 4, 7, 10 days) | TCA/acetone; 2DE MALDI-TOF; nanoLC-ESI-Q-TOF MS/MS | 91 DAP (74 identified proteins) Genotypic differences: GLP3–7, GLP12, β-1,3-glucanase, ATP synthase CF1 β–higher in T; GLP5a, PR17–higher in S | Witzel et al., 2014 |

COMBINED STRESS

| Plant material | Treatment | Methods | Major differentially-abundant proteins (DAP) | References |
|----------------|-----------|---------|---------------------------------------------|------------|
| Osmotic stress or salinity–common wheat (T. aestivum) Jinan 177 (S), T. aestivum × Thinopyrum ponticum Shanrong 3 (T)–root, leaf | ½Hoagland solution 18% PEG-6000 or 200 mM NaCl (24 h) | TCA/acetone; 2DE MALDI-TOF/TOF | 93 (root), 65 (leaf) differentially abundant proteins; 34 (root), 6 (leaf)–genotypic differences PEG: 38 root, 39 leaf; Salinity: 52 root, 52 leaf proteins PEG-specific proteins: ribosomal protein S8 (↓) Salt-specific proteins: importin α 1b (root), Genotypic differences: chl a/b binding apoprotein CP24 precursor, DWARF3–higher in T | Peng et al., 2009 |
| Drought and heat Barley–Syrian landrace Arta (T), Australian cv. Keel (T)–leaf (heading stage) | Drought: 50% FWC (control), 15% FWC (stress) for 3 days Heat: 36°C (4 h) | TCA/acetone; 2DE, 2D-DIGE MALDI-TOF/TOF | 99 DAP Heat–up: FBP ALDO, chaperones, proteases, eEF-G, elF4A, RubisCO activase B Genotypic differences (14 proteins): photosynthesis-related proteins (LHCl type III Lhcb3, OEE1 PsbO, RubisCO activase B)–higher in Keel than Arta | Rollins et al., 2013 |
| Drought or waterlogging and cold–winter common wheat cv. Yannong 19–leaf | Drought + LT: 35% FWC (7 days) Waterlogging + LT (7 days) | TCA/acetone; 2DE MALDI-TOF/TOF | 32 identified proteins Up: DHAR, GP, Hsp70; Down: C metabolism–related proteins (glycolysis, TCA, Krebs cycle), RubisCO activase A, ATP synthase CF1 α,β | Li et al., 2014 |

| **Boron** | | | | |
| Barley Clipper (S) × Sahara (T) DH lines–leaf, root | 1 mM H$_2$BO$_3$ (S), 5 mM H$_2$BO$_3$ (T) for 14 days | PBS pH 7.5, TCA/acetone; 2D-nanoLC-MS/MS iTRAQ | 138 (leaf), 341 (root) identified proteins Up: IDS2, IDS3, methyl-thioribose kinase Leaf: PRK, PGK, PGM, ENO, PC, RubisCO activase, eEF1-α, β, γ; eEF-G, eEF-Tu; TLP; Cu/Zn-SOD; 50S ribosomal protein L3; 60S ribosomal protein L1 Root: CCOMT, class III POX, chitinase, 26S proteasome, β-1,3-glucanase; ATP synthase CF1 β, IDS2, IDS3; Hsp70; Hsc70; 40S ribosomal protein S5 | Patterson et al., 2007 |
| **Copper** | | | | |
| Common wheat cv. Yumai 34–leaf, root | 100 μM CuSO$_4$ (3 days) | TCA/acetone; 2DE MS/MS | 98 DAP [93 identified proteins–43 (leaf), 49 (root)] 36 Cu-responsive proteins Leaf: 14-3-3; MDH, TPI; PD; V-ATPase A; ATP synthase CF1 α; carboxic anhydrase, RubisCO activase, PSI subunit VII (PsaC); Root: 14-3-3, translationally-controlled tumor protein; Hsp70, APX, GST, Cu/Zn-SOD, PR10; TPI; ATP synthase CF1 α; actin 1, tubulin | Li et al., 2013 |
| **Nitrogen** | | | | |
| Common wheat cv. Arche, Récital–leaf | 2, 8, 20 mg N/plant/d for 60 days | TCA/acetone; 2DE LC-MS/MS | 76 DAP (14 identified proteins) FBP ALDO, PGK, PGM, ENO2, MDH; RubisCO activase A, OEE1 (PsbO); 2-Cys Prx | Bahrman et al., 2004 |
| **PATHOGENS** | | | | |
| **Fusarium culmorum and F. graminearum** (teleomorph Gibberella zeae) | | | | |
| Barley cv. Scarlett (S)–young spikelet | artificial inoculation F. Graminearum–3 days | Acetone; 2DE MALDI-TOF | 51 DAP (50 identified) Up: PR proteins (PR-1,2,3,5,9,15); proteolytic fragments of β-aminase induced by pathogen | Yang et al., 2010a |
| Barley cv. Scarlett (S)–mature grain | artificial inoculation F. Graminearum–72 h; 15, 100 kg ha$^{-1}$ N | 5 mM Tris-HCl pH 7.5 (water soluble proteins), 2DE MS/MS | Up: 80 proteins (serpin, protease inhibitors CI-1A, CI-1B) Down: 108 proteins (albumins) 65 proteolytic fragments (albumins, serpin, protease inhibitors) 9 proteins of F. graminearum (peptidyl-prolyl cis-trans isomerase, Cu/Zn-SOD, L-xyulose reductase) Positive effect of increased N on plant resistance | Yang et al., 2010b |
| Naked barley (Hordeum vulgare ssp. nudum)–mature grain | 1.2 mg/kg DON (artificial inoculation F. culmorum and F. graminearum) | 50 mM Tris-HCl pH 7.4; NEPHGE 2-DE MALDI-TOF nanoLC-MS/MS | 11 identified proteins Up: DNA-dependent RNA-polymerase; Dof zinc-finger protein, NBS-LRR (transcription regulation); serpin I3 spots; serine | Eggert and Pawelzik, 2011 |
### Common Wheat Genotypes

| Plant material | Treatment | Methods | Major differentially-abundant proteins (DAP) | References |
|----------------|-----------|---------|---------------------------------------------|------------|
| Emmer (Triticum dicoccum)–mature grain | 10 mg/kg DON (artificial inoculation) TCA/acetone; 2DE nanoLC-MS/MS | 10 identified proteins Up: serpin (serine protease inhibitor), TLP; β-amylase, globulin Down: POX, Prx; glycosyltransferase; chininase; α-gliadin | Eggert et al., 2011 |
| Puccinia triticina | Common wheat cv. Thatcher (S), NIL Thatcher Lr1 (T)–leaf 3, 6, 9 days after artificial infection TCA/acetone; 2DE qTOF-MS/MS | 32 identified proteins (S); T showed no reproducible response Up: eEF1-β, eIF5A2, 20S proteasome subunit α-1, ribosomal protein P0; TPI; dihydroliopasomide acetyl transferase; α-tubulin; Hsp70, CPN60; ATP synthase CF1 β; peptidyl-prolyl cis-trans isomerase | Rampitsch et al., 2006 |
| Septoria tritici (teleomorph Mycosphaerella graminicola) | Common wheat cv. Sevin (S), Stakado (T)–leaf 3, 7, 11 days after artificial infection Phenol extraction; phosphoprotein separation; Poros Oligo R3 micro-column; LC-MS/MS | Plant: Phosphoproteins (70 in T, 60 in S)–signaling (CDPK, MAPK); transport (PIP ATPase)–higher in T than S Pathogen: 31 proteins, 5 phosphoproteins (G-proteins, 14-3-3; Ras GTPase; ABC transporter) | Yang et al., 2013 |

**Abbreviations:** 2Cys-Prx, 2-cysteine peroxiredoxin; 2DE, two-dimensional electrophoresis; 2D-DIGE, two-dimensional differential in-gel electrophoresis; β-CAS, β-cyanohydrin synthase; ABA, abscisic acid; ACP, acyl carrier protein; ADP-Glucose pyrophosphorylase; AOX, alternative oxidase; APX, ascorbate peroxidase; AT, tolerant (genotype); B, glyceraldehyde-3-phosphate dehydrogenase B form; CDPK, calcium-dependent protein kinase; DAP, differentially abundant proteins; DH, double haploid (line); DHAR, dehydroascorbate reductase; DON, deoxynivalenol; ENO, enolase; FBP ALDO, fructose-1,6-bisphosphate aldolase; FWC, field water capacity; GAPDH, glyceraldehyde-3-phosphate dehydrogenase; GAPDH B, glyceraldehyde-3-phosphate dehydrogenase B form; GH3, glutamine synthetase; GST, glutathione S-transferase; HFLC, high performance liquid chromatography; Hsc70, heat shock cognate protein 70; iTRAQ, isobaric tag for relative and absolute quantification; LC, liquid chromatography; LEA, Late embryogenesis-abundant (protein); LOK, lipoygenase; LTO-FTICR, linear quadrupole trap-Fourier transform ion cyclotron resonance; MALDI-TOF/TOF, matrix-assisted laser desorption ionization time-of-flight/time-of-flight (spectrometry); MAPK, mitogen-activated protein kinase; MDAR, monodehydroascorbate reductase; MDA6, malate dehydrogenase; MS, mass spectrometry; MSSP2, monosaccharide sensing protein2; NBS-LRR, nucleotide-binding site leucine-rich repeat protein; NEPHGE, non-equilibrium pH gel electrophoresis; NDPK, nucleoside diphosphate kinase; NIL, near-isogenic line; OEE, oxygen evolving enhancer (protein); PDS, phosphate buffer saline; PC, plastocyanin; PDI, protein disulfide isomerase; PDX, pyridoxal biosynthesis protein; PEG, polyethylene glycol; PGK, phosphoglycerokinase; PGM, phosphoglyceromutase; POX, peroxidase; PPDF, pyruvate phosphate dikinase; PRK, phosphoribulokinase; Prx, peroxiredoxin; PS, photosystem; PVP, polyvinyl pyrrolidone; qTOF, quadrupole time-of-flight; Rubisco CO, ribulose-1,5-bisphosphate carboxylase/oxygenase; Rubisco LSU, Rubisco large subunit; Rubisco SSU, Rubisco small subunit; RWC, relative water content; S, sensitive (genotype); SA, salicylic acid; SHMT, serine hydroxymethyltransferase; SnRK, sucrose non-fermenting-related protein kinase; SOD, superoxide dismutase; SUS1, sucrose synthase 1; T, tolerant (genotype); TCA, trichloroacetic acid; TLP, thaumatin-like protein; TPI, triose phosphate isomerase; Tx, thioredoxin; V-ATPase, vacuolar ATPase; VDAC, voltage-dependent anion channel; WSC, Wheat Cold-specific (protein); WRAB, Wheat responsive to-ABA (protein); XET, xyloglucan endo-transglycosylase.

Differentially-tolerant genotypes may help researchers to identify key proteins underlying the differences in stress tolerance. The aim of this minireview is to summarize the major results obtained by proteomic studies in temperate cereal crops wheat and barley studied under abiotic and biotic stresses. Proteins affected by differential stress factors and proteins revealing a differential response between differentially-tolerant wheat and barley genotypes are discussed in a greater detail. Possibilities of utilization of proteins revealing a differential stress response between tolerant and sensitive genotypes as protein markers in breeding programs aimed at improvement of stress tolerance are suggested.

**COMMON FEATURES OF STRESS RESPONSE AT PROTEOME LEVEL**

Plant stress response is a dynamic process aimed at an enhancement of plant stress tolerance and an establishment of a novel homeostasis between plant and environment (Figure 1). Several
phases of plant stress response could be distinguished including an alarm phase, an acclimation phase, a resistance phase, an exhaustion phase when stress is too severe or lasts too long, and a recovery phase after a cessation of the given stress factor (Levitt, 1980; Larcher, 2003; Kosová et al., 2011). At proteome level, profound alterations in protein relative abundance were found between stressed and control plants as well as between differential genotypes (Table 1). During an alarm phase, stress induces profound alterations in proteins involved in cell signaling although these proteins are detected scarcely on 2DE gels due to their low abundance. An increase in 14-3-3 proteins as well as translationally controlled tumor protein homologs was detected in copper- and water-stressed wheat (Kang et al., 2012; Ghabooli et al., 2013; Li et al., 2013; Alvarez et al., 2014) and barley (Wendelboe-Nelson and Morris, 2012) and genotype-specific responses of β subunit of heterotrimeric G protein were found in salt-stressed wheat (Peng et al., 2014) and components of mitochondrial ATP-synthase, namely β subunit of CF1 complex (Bahrman et al., 2004; Patterson et al., 2007; Vítámvás et al., 2012; Budak et al., 2013; Kosová et al., 2013b; Rollins et al., 2013; Xu et al., 2013) indicating an enhanced demand for energy.

Regarding photosynthesis, an increase or a decrease in several photosynthetic proteins (proteins involved in primary photosynthetic reactions, carbon fixation, and Calvin cycle) have been observed depending on the severity of stress (Caruso et al., 2008, 2009; Ye et al., 2013). A downregulation of photosynthesis reactions under severe stress is reflected at proteome level by a decrease in D1 and D2 proteins in photosystem II reaction center (RC PSII), proteins of oxygen evolving complex (OEC), a decrease in chlorophyll a-b binding proteins in both photosystem (PS) I and II, a decrease in Fe-S complex in PSI, a downregulation of Rubisco and key Calvin cycle enzymes phosphoglycerate kinase and phosphoribulokinase in cold- and waterlogging-treated winter wheat (Li et al., 2014), salt-treated durum wheat (Caruso et al., 2008) and in drought-treated barley (Ghabooli et al., 2013) while an increase in OEC protein OEE2 was found in salt-treated barley (Rasoulinia et al., 2011; Fatehi et al., 2012). In addition, an
increase in proteins with stimulating and protective functions such as RubisCO activase A (Bahrman et al., 2004; Caruso et al., 2008, 2009; Fatehi et al., 2012; Budak et al., 2013), a thermostable RubisCO activase B (Rollins et al., 2013), carbonic anhydrase (Caruso et al., 2008) and RubisCO large and small subunit binding proteins CPN60-α and CPN60-β was observed under various stresses (Caruso et al., 2008; Sarhadi et al., 2010; Kang et al., 2012; Budak et al., 2013; Kosová et al., 2013b; Xu et al., 2013).

An increased demand on energy under stress acclimation corresponds with a decreased abundance of enzymes (fructokinase-2, sucrose synthase-1) involved in biosynthesis of energy-rich compounds such as starch and a decrease in storage proteins (11S seed storage protein 2-like, legumin-like protein; Vitámvás et al., 2012; Kosová et al., 2013b).

Stress acclimation also reveals an enhanced demand on protein metabolism including both protein biosynthesis and degradation. Changes in the levels of eukaryotic translation initiation factors eIF3 subunit 1, eIF5A2 (Kosová et al., 2013b), eIF4A (Rollins et al., 2013) and elongation factor eEF1-α (Budak et al., 2013), several ribosomal proteins, e.g., 60S proteins P0, P2A, L3, L38 (Fercha et al., 2014), or chloroplastic ribosomal proteins 30S-3, 30S-L12 (Ghabooli et al., 2013; Gharechahi et al., 2014), as well as proteasome subunits such as 20S proteasome subunit α-type 1 and 6 (Rampitsch et al., 2006; Rinalducci et al., 2011a; Fercha et al., 2013; Ghabooli et al., 2013) and proteins of ubiquitin pathway involved in proteasome targeting such as ubiquitin conjugating enzyme E2 variant IC like (Kosová et al., 2013b) were reported indicating an enhanced protein turnover during stress acclimation.

Stress represents an enhanced risk of protein damage due to imbalances in cellular homeostasis. Therefore, increased abundances of several proteins with chaperone and other protective functions have been reported. Extreme temperatures, but also drought, pathogens, and other stresses cause an enhanced risk of protein misfolding and they are thus associated with an enhanced accumulation of chaperones from HSP superfamily, namely HSP70 (Rampitsch et al., 2006; Li et al., 2013; Rollins et al., 2013), HSP100 (Clp protease; Ashoub et al., 2013), and small HSPs (Sylas et al., 2002; Majoul et al., 2004; Hajheidari et al., 2007), but also others such as chaperon chaperone (Vitámvás et al., 2012; Hlaváková et al., 2013), serpins (Yang et al., 2010b; Fercha et al., 2013, 2014), and protein disulfide isomerase (Hajheidari et al., 2007; Vitámvás et al., 2012; Li et al., 2013). However, a decrease in HSP90 was reported under cold (Vitámvás et al., 2012). Disorders in cellular metabolism under stress lead to an enhanced risk of oxidative damage. At proteome level, an increased abundance of several reactive oxygen species (ROS) scavenging enzymes was found practically under each kind of stress (Hajheidari et al., 2007; Ford et al., 2011). Plants try to reduce a risk of ROS formation by several ways. The major one represents a down-regulation of photosynthesis reactions which is associated with a decrease in D1 and D2 proteins in photosystem II reaction center (RC PSI1), proteins of OEC, RubisCO small subunit and key Calvin cycle enzymes phosphoglycerate kinase, phosphoribulokinase and transketolase (Caruso et al., 2008; Ford et al., 2011; Ashoub et al., 2013). Other indirect ways how to reduce ROS lie in a reduced uptake of metal ions, especially iron, which can act as catalysts of ROS formation. A reduced level of protein ID12 and dioxygenases IDS2, IDS3 involved in iron uptake and phytosiderophore biosynthesis was found by Witzel et al. (2009) in salt-treated barley roots while an increased level of these enzymes was found by Patterson et al. (2007) in barley grown under elevated boron.

Several stresses including drought, heat, salinity, cold, but also mechanical wounding, induce an enhanced accumulation of proteins belonging to LEA superfamily. Late embryogenesis-abundant (LEA) superfamily includes at least five subclasses, the most important being LEA-II (dehydrons) and LEA-III proteins whose transcript and protein levels, and also phosphorylation level, have been reported to correlate with wheat and barley tolerance to low temperatures (Crosatti et al., 1995; Vágújfalvi et al., 2000, 2003; Vitámvás et al., 2007; Kosová et al., 2008c; 2013c; Sarhadi et al., 2010), drought (Labhilili et al., 1995; Brini et al., 2007) and other stresses.

Several stresses, especially biotic ones, are associated with an induction of protective proteins from PR superfamily. Pathogenesis-related (PR) proteins encompass 16 groups involved in defense against microbial and fungal pathogens (Edreva, 2005). Many of PR proteins can resist acidic pH, they reveal enzymatic activities aimed at modifications of cell wall, and ROS scavenging functions (some germins and germin-like proteins reveal manganese superoxide dismutase (Mn-SOD) and oxalate oxidase activities). An enhanced abundance of several PR proteins was reported not only in cereals exposed to fungal pathogens such as Fusarium (class-II chitinase, β-amyrase, thaumatin-like protein, PR9–peroxidase; Yang et al., 2010a,b; Eggert and Pawelzik, 2011; Eggert et al., 2011), but also under abiotic stresses such as cold (β-1,3-glucanase, chitinase, PR4, thaumatin-like protein; Sarhadi et al., 2010; Kosová et al., 2013b; Gharechahi et al., 2014), salinity (germin-like protein, PR10; Fatehi et al., 2012; Kamal et al., 2012; Witzel et al., 2014), and others.

Stresses also affect other aspects of cellular metabolism. An increased abundance of methionine synthase catalyzing formation of methionine or S-adenosylmethionine synthase (SAMS) catalyzing formation of S-adenosylmethionine (SAM) has been reported (Bahrman et al., 2004; Patterson et al., 2007; Witzel et al., 2009; Vitámvás et al., 2012; Kosová et al., 2013b; Xu et al., 2013). SAM represents not only a universal methyl donor in regulation of DNA heterochromatin formation and gene expression, but it is also a precursor of several stress-related metabolites as glycine betaine, polyamines, hydroxymugineic acids (phytosiderophore precursors; Mori and Nishizawa, 1987) and ethylene. Alterations in glutamine synthetase (GS) have been reported under drought (Ford et al., 2011; Kang et al., 2012) and cold (Hlaváková et al., 2013) indicating an important role of nitrogen assimilation and proline biosynthesis in stress acclimation.

Stress affects cellular transport and membrane properties. An enhanced need for ion transport and thus an associated increase in plasma membrane and tonoplast ion transporters such as V-ATPase has been reported not only under salinity (Peng et al., 2008), but also under other stresses such as drought (Ghabooli et al., 2013), heat (Majoul et al., 2004) and osmotic stress (Ye et al., 2013; Zhang et al., 2014). Differential phosphorylation of several transport proteins such as aquaporins, H^+–ATPase or
monosaccharide sensing protein 2, was also reported in response to stress (Zhang et al., 2014). The effect of several stresses on cell wall remodeling is indicated by alterations in several enzymes involved in lignin metabolism such as caffeoyl-coenzyme A O-methyltransferase (CCOMT) indicating an important role of cell wall in plant stress response (Sugimoto and Takeda, 2009; Ghabooli et al., 2013).

Long-term and regularly occurring stress factors such as cold during winter also affect plant development. At proteome level, significant changes in the level of small glycine-rich RNA-binding proteins (sGRPs) and in lectins, glycoproteins involved in saccharide signaling, were found in wheat (Rinalducci et al., 2011b; Kosová et al., 2013b). Ricin B lectin 2 was reported to be induced by cold in crowns of both winter barley (Hlaváčková et al., 2013) and winter wheat (Kosová et al., 2013b). Lectin VER2 was reported to accumulate in winter wheat shoot apex until vernalization (Yong et al., 2003; Rinalducci et al., 2011b). Differences in sGRPs and VER2 levels between spring and winter wheat growth habits indicate a differential response to cold within wheat germplasm (Kosová et al., 2013b).

PROTEINS REVEALING A DIFFERENTIAL RESPONSE BETWEEN STRESS-TOLERANT AND STRESS-SENSITIVE GENOTYPES

A differential ability of various wheat and barley genotypes to cope with several stresses is reflected also at protein level. Stress-tolerant genotypes do not suffer from a disruption of energy metabolism when exposed to moderate stress levels; moreover, when exposed to stress, they can increase an abundance of key enzymes of energy metabolism to increase ATP production as indicated by a differential response observed in several photosynthesis-related proteins (RubisCO subunits, RubisCO activase), ROS scavenging enzymes as well as respiration (Krebs cycle) enzymes. Quantitative differences in Krebs cycle enzymes such as mitochondrial NADH-dependent MDH between two differentially frost-tolerant winter wheats (Vítámvás et al., 2012), in aconitase (Budak et al., 2013), thioredoxin h and glutathione-S-transferase (GST; Hajheidari et al., 2007; Sarhadi et al., 2010), lipoxygenase 1 and 2 (Alvarez et al., 2014) between differentially drought-tolerant wheats; in Cu/Zn-SOD, Mn-SOD (Ford et al., 2011; Xu et al., 2013), glyoxysomal MDH (gMDH; Ashoub et al., 2013), GST (Rasoulnia et al., 2011), class III peroxidase, catalase and lipoxygenase (Wendelboe-Nelson and Morris, 2012) between differentially drought- and salt-tolerant barleys; in Mn-SOD, MDH and aconitase between salt-treated wheat and wheat × Lophopyrum elongatum amphiploid (Jacoby et al., 2013), and a downregulation of MDH and isocitrate dehydrogenase in cold-sensitive spring wheat (Rinalducci et al., 2011a) indicate a crucial role of mitochondrial respiration and ROS metabolism in stress acclimation. Along with these data, a differential abundance in storage proteins such as legumin-like protein between two differentially frost-tolerant winter wheats was found by Vítámvás et al. (2012) indicating a higher demand on energy ensured by storage compound degradation in the less-tolerant genotype. Moreover, tolerant genotypes can also afford to accumulate higher amounts of stress-protective proteins such as PR proteins (Witzel et al., 2014) and ABA-responsive proteins (Alvarez et al., 2014). A significant correlation between wheat WCS120 and barley DHN5 dehydrin relative accumulation and acquired frost tolerance (FT) determined as lethal temperature for 50 % of the sample (LT50) was reported for winter genotypes grown under both cold and moderate cold temperatures (Vítámvás et al., 2007, 2010; Kosová et al., 2008c, 2013c). WCS120 and DHN5 can be thus considered promising FT markers.

Stress-tolerant and stress-sensitive genotypes or related plant species also reveal significant differences in proteins involved in regulation of cell cycle and plant development. Factor eIF5A2 does not only regulate translation initiation, but it is also known to participate in the regulation of cell cycle switch between cell proliferation and death (Thompson et al., 2004). Under salinity, a decreased abundance of eIF5A2 with respect to control was found in both salt-sensitive common wheat and salt-tolerant *T. aestivum* × *Thinopyrum ponticum* hybrid (Wang et al., 2008); however, a decrease in *T. aestivum* × *Th. ponticum* was much lower than in *T. aestivum* indicating a higher cell proliferation rate in the salt-tolerant hybrid. A differential abundance in lectin VER2 between cold-treated spring and winter wheat cultivars corresponds to a differential developmental response with a winter wheat revealing a developmental arrest while a spring wheat revealing a progression to reproductive phase as indicated at proteome and phytohormone levels (Kosová et al., 2012, 2013b).

CONCLUSIONS AND FUTURE PERSPECTIVES

Both abiotic and biotic stress factors induce an active plant stress response including a profound reorganization of plant proteome. Comparative proteomic studies are usually carried out on a limited range of plant material due to their expensiveness and much of sophisticated work. However, they can significantly contribute to identification of novel proteins revealing a differential response in abundance or PTMs between differentially-tolerant genotypes and representing potential protein markers of stress tolerance. The potential markers should be tested on a broad range of genotypes using simple protein quantification methods as ELISA or immunoblots which can be utilized by breeders. As an example, proteomic studies on cold-treated winter wheats resulting in an identification and testing of dehydrin proteins as FT markers can be given (Vítámvás et al., 2007, 2010). Recent publication of draft barley (The International Barley Genome Sequencing Consortium, 2012) and wheat (The International Wheat Genome Sequencing Consortium, 2014) genome sequences will significantly contribute to protein identification, sequential characterization and preparation of specific antibodies which will stimulate further research and applications in breeding for an improved stress tolerance.

AUTHOR CONTRIBUTIONS

Klára Kosová has outlined the idea and prepared the text. Pavel Vítámvás and Ilja T. Prášil contributed to preparation, drafting, critical reading, and publication of the manuscript.

ACKNOWLEDGMENTS

The work was supported by projects from Ministry of Education, Youth and Sports of the Czech Republic (MEYS CZ) LD14064 and LD14087 as a part of of COST actions FA1204 and FA1208,
respectively. The work was also supported by an institutional project MZE RO0414 from Ministry of Agriculture of the Czech Republic (MZe CZ).
