KAC-MOODY GROUPS AND COSHEAVES ON DAVIS BUILDING

KATERINA HRISTOVA AND DMITRIY RUMYNIN

Abstract. We investigate smooth representations of complete Kac-Moody groups. We approach representation theory via geometry, in particular, the group action on the Davis realisation of its Bruhat-Tits building. Our results include an estimate on projective dimension, localisation theorem, unimodularity and homological duality.

Our investigation of representation theory of Kac-Moody groups aims to combine two known lines of inquiry. Bernstein in his 1992 lectures in Harvard [1] proposed to look at representation theory of $p$-adic groups through a geometric prism, à la Klein. A $p$-adic group $H$ acts on a space, its Bruhat-Tits building $BT$. A careful study of this action brings new, useful insights into representation theory of $H$. This approach culminated in the 1997 seminal work by Schneider and Stuhler [21] where they developed a systematic approach for passing from representations to equivariant objects on $BT$, an ultrametric rendition of the Beilinson-Bernstein localisation.

The second line comes from the 2002 influential work by Dymara and Januszkiewicz. They pioneered a method for computing cohomology of a Kac-Moody group $G$ by studying cohomology of $BT$ and its Davis realisation $D$ [8].

In the present paper we examine the smooth representations of a Kac-Moody group $G$ by localising them over $D$. Thus, we unify the two lines of inquiry described above. A natural question is whether it is possible to use $BT$ rather than $D$. It is possible only for those Kac-Moody groups $G$ that are hyperbolic in the following sense: any proper Dynkin subdiagram is of finite type. In particular, affine Dynkin diagrams are hyperbolic, so our results are applicable to algebraic groups over local fields and their Bruhat-Tits buildings.

Let us now explain the content of the present paper. We strive to cover the correct generality in our results, the generality where our proofs work. The price we pay for this is that the different sections of the paper have different assumptions. Let us go section by section explaining our results and our assumptions.

In Section 1 we collect some useful results about Haar measure on a locally compact totally disconnected topological group $G$. One particular twist is that our
Haar measure takes values in a field of a possibly positive characteristic. We introduce Hecke algebra. While we follow Bushnell and Henniart [4] in our treatment, we do not assume unimodularity. In particular, we formulate a useful criterion for unimodularity (Proposition 1.2).

In Section 2 we keep the same assumptions on the group $G$ as in Section 1, in particular, $G$ is not necessarily unimodular. In perspective, we would like to cover the group $GL_n(K)$ over a local field $K$. When $GL_n(K)$ acts on $BT$, the stabilisers are not compact, just compact modulo centre. So we choose a central subgroup $A$ of $G$, modulo which we can effectively describe geometry and representation theory. In particular, we introduce the abelian category $M_A(G)$ of $A$-semisimple smooth representations of $G$ over a field $F$. We follow Bushnell and Henniart [4] to show that $M_A(G)$ is equivalent to a category of representations of a Hecke algebra (Theorem 2.5). The pay-off is existence of enough projectives in $M_A(G)$ (Corollary 2.7).

We study these projectives in Section 3. We also start contemplating projective resolutions. If $(P_\bullet, d_\bullet)$ is a resolution of the trivial module, then $(P_\bullet \otimes V, d_\bullet \otimes I_V)$ is a projective resolution of any module $V$ (Lemma 3.3). At this point we prove our first main theorem à la Bernstein (Theorem 3.4): if $G$ acts on a contractible simplicial complex $\mathcal{X}$, the projective dimension of $M_A(G)$ is bounded above by the dimension of $\mathcal{X}$. We follow Gelfand and Manin [12, Chapter 1] with simplicial notation and terminology: by $\mathcal{X}$ we denote a simplicial complex, by $\mathcal{X}_\bullet = (\mathcal{X}_n, \mathcal{X}(f))$ – a simplicial set, by $|\mathcal{X}|$ – the geometric realisation of $\mathcal{X}_\bullet$. In particular, $G$ acting on $\mathcal{X}_\bullet$ means action on each set $\mathcal{X}_n$, commutation of the action with the face maps $\mathcal{X}(f)$ and openness of all stabilisers.

In Section 4 we adopt the assumptions coming from Theorem 3.4: the group (as before) $G$ acts on a simplicial (not necessarily contractible) set $\mathcal{X}_\bullet$. We investigate $G$-equivariant cosheaves and sheaves (also known as coefficient systems in homology and cohomology) on $\mathcal{X}_\bullet$. We prove our second main theorem à la Schneider-Stuhler (Theorem 4.7). It is a localisation theorem clarifying the interface between $M_A(G)$ and $G$-equivariant cosheaves on $\mathcal{X}_\bullet$.

Since $\mathcal{M}(G)$ is a Noetherian category, a finitely generated module admits a finitely generated projective resolution. However, the resolution $(P_\bullet, d_\bullet)$ in Theorem 3.4 is not finitely generated. The goal of Section 5 is to chase a construction of a finitely generated resolution. Such resolution for $p$-adic algebraic groups is constructed by Schneider and Stuhler by choosing a suitable cosheaf on the Bruhat-Tits building $BT_\bullet$. Inspired by their approach, we propose a similar construction in Conjecture 5.4, proving only the 1-dimensional case in Theorem 5.5. We lack several crucial tools available to Schneider and Stuhler. Firstly, the Davis building $D_\bullet$ of a general type is not as well behaved as an affine $BT_\bullet$. Secondly, we lack Bernstein’s Theorem that certain subcategories of $M_A(G)$ are closed under subquotients [21, Th. I.3]. To overcome these difficulties, we propose to utilise the metric properties of $|D_\bullet|$, which is a CAT(0)-space by Davis’ Theorem. This controls the assumptions of Section 5: we work with a locally compact totally disconnected $G$ acting on a simplicial set $\mathcal{X}_\bullet$, whose geometric realisation $|\mathcal{X}|$ admits a CAT(0)-metric.

Our assumptions naturally evolve in Section 6. We assume that $G$ is a topological group of Kac-Moody type, i.e., it admits a generalised BN-pair with certain topological properties. The main result of the section is Theorem 6.4, a description of the Davis building $D_\bullet$ for such a group $G$. Consequently, all results from
previous sections are applicable to $G$. Another important result is Theorem 6.6: a topological group of Kac-Moody type is unimodular.

Notice that the Davis building is often called the Davis realisation of Bruhat-Tits building in the literature. Our terminology is justified: $\mathcal{B}^T_e$ and $\mathcal{D}_e$ are distinct simplicial sets. They are homotopic if the Dynkin diagram has no connected components of finite type, but they are both homotopic to a point in this case. Both of them can be obtained from the same chamber system, yet by different means. We misapprehend why $\mathcal{D}$ is “a realisation” of $\mathcal{B}^T$. On the contrary, we feel they are quite distinct objects.

The Kac-Moody groups emerge in the penultimate Section 7. Given a root datum $\mathcal{D}$, we explain how the corresponding Kac-Moody group over a finite field $G_{\mathcal{D}}(\mathbb{F}_q)$ leads to a topological group of Kac-Moody type. Further details and proofs will be available in an upcoming paper by Capdeboscq and Rumynin [5].

The final Section 8 has similar assumptions to Section 6. We initiate the study of the homological duality for smooth $G$-modules. Origins of homological duality go back to Hartshorne [13]. For $p$-adic groups the duality was first introduced by Bernstein and Zelevinsky [2]. In our approach we are influenced by the work of Yekutieli on the duality for modules over noncommutative rings [23] as well as Bernstein’ lecture notes [1]. We formulate two conjectures 8.2 and 8.4 on homological duality at the end of this paper. We will address these conjectures in future research.

1. Haar Measure for Totally Disconnected Groups

Let $G$ be a locally compact totally disconnected topological group. If $K$ is a compact open subgroup, we can choose a left Haar measure $\mu_K$ on $G$ with $\mu_K(K) = 1$. We denote the modular function by $\Delta : G \to \mathbb{R}_{>0}^\times$.

Now let $I$ be the set of indices $|K : C|$ of all compact open subgroups $C \leq K$. Let $\mathcal{Z}_{(K)}$ be the ring of fractions on $\mathbb{Z}$ obtained by inverting all numbers $n \in I$.

**Lemma 1.1.** If $A \subseteq G$ is a Borel set, then $\mu_K(A) \in \mathcal{Z}_{(K)} \cup \{\infty\}$. Moreover, $\Delta(x) \in \mathcal{Z}_{(K)}$ for all $x \in G$.

**Proof.** The topology admits a basis at $e$ consisting of compact open subgroups [14 II.7.7]. If $C$ is a compact open subgroup, then it is commensurable to $K$, hence

$$\mu_K(C) = \frac{|C : (C \cap K)|}{|K : (C \cap K)|} \in \mathcal{Z}_{(K)}.$$

Since $A$ is a disjoint union of left cosets of various compact open subgroups, $\mu_K(A) \in \mathcal{Z}_{(K)} \cup \{\infty\}$. Finally, $\Delta(x) = \mu_K(Kx) \in \mathcal{Z}_{(K)}$. $\square$

Let $\mathbb{F}$ be a field of characteristic $p$ (possibly $p = 0$) equipped with the discrete topology. We say that the field (or its characteristic) is $K$-modular, if $p$ divides the order $|K|$. Similarly, it is $K$-ordinary, if $p$ does not divide $|K|$. Recall that the order $|K|$ of a profinite group $K$ is a supernatural number $\prod_p p^{n_p}$ with $n_p \in \{0, 1, \ldots, \infty\}$ that is the least common multiple of orders of $K/H$ for various open subgroups $H \leq K$.

A continuous function $\Theta : G \to \mathbb{F}$ is locally constant and, consequently, smooth. In fact, the sets of smooth functions, continuous functions and locally constant functions coincide.
If the characteristic $p$ is $K$-ordinary, then there is a natural ring homomorphism $\mathbb{Z}_p(K) \to \mathbb{F}$. Thus, by Lemma [11] we may think that the measure $\mu_K$ and the modular function $\Delta$ take values in $\mathbb{F}$. In particular, given a compactly supported smooth function $\Theta : G \to \mathbb{F}$, one can compute its integral $\int_G \Theta(x)\mu_K(dx) \in \mathbb{F}$.

The $\mathbb{F}$-vector space $\mathcal{H} = \mathcal{H}(G, \mathbb{F}, \mu_K)$ of all compactly supported smooth functions $\mathcal{H}$ is a commutative algebra under pointwise multiplication $\bullet$ and the Hecke algebra under the convolution product $[4]$

$$\Psi \cdot \Theta(x) = \int_G \Psi(y)\Theta(y^{-1}x)\mu_K(dy).$$

This multiplication depends on the choice of the compact open subgroup $K$ such that the field is $K$-ordinary. If no such $K$ exists, there is no Hecke algebra as defined here. If two such subgroups $K$ and $K'$ are chosen, the measures are scalar multiples of each other: $\mu_K = \alpha\mu_K'$. Hence, the corresponding Hecke algebras $(\mathcal{H}, \bullet)$ and $(\mathcal{H}, \bullet')$ are isomorphic:

$$f(\Psi \cdot \Theta) = f(\Psi) \cdot f(\Theta) \quad \text{where} \quad f(\Psi) = \alpha \Psi.$$

The Hecke algebra $(\mathcal{H}, \bullet)$ is associative but contains no identity unless $G$ is discrete. The identity should be the delta-function at $e \in G$ but it is not well-defined. Instead $\mathcal{H}$ contains a family of idempotents approximating identity. For a compact open subset $U$ we define a function $\Lambda_U \in \mathcal{H}$ by $\Lambda_U(x) = 0$ if $x \notin U$ and $\Lambda_U(x) = 1/\mu_K(U)$ if $x \in U$. Now take a basis of topology at $e$ consisting of all compact open subgroups. Then the functions $\Lambda_K$ as $K$ runs over this basis of topology form a family of idempotents approximating identity.

It is convenient for computations when the group $G$ is unimodular. If $G$ is not unimodular, the modular function shows up in the change of variables $y = x^{-1}$. Equation (1)

$$\mu_K(dx) \xrightarrow{y=x^{-1}} \Delta(y)\mu_K(dy).$$

is also useful to contemplate the behaviour of the counit $\phi$ and the antipode $\sigma$:

$$\phi : \mathcal{H} \to \mathbb{F}, \quad \sigma : \mathcal{H} \to \mathcal{H}, \quad \phi(\Theta) = \int_G \Theta(x)\mu_K(dx), \quad \sigma(\Theta)(x) = \Theta(x^{-1}).$$

Equation (1) leads to an interesting interaction between the antipode and the counit:

(2) \[ \phi(\sigma(\Theta)) = \int_G \Theta(x^{-1})\mu_K(dx) \xrightarrow{y=x^{-1}} \int_G \Theta(y)\Delta(y)\mu_K(dy) = \phi(\Theta \bullet \Delta). \]

Despite the non-unimodularity the antipode is still an anti-automorphism

(3) \[ \sigma(\Psi \bullet \Theta)(x) = \Psi \bullet \Theta(x^{-1}) = \int_G \Psi(y)\Theta(y^{-1}x^{-1})\mu_K(dy) \xrightarrow{z=xy} \int_G \Theta(z^{-1})\Psi([z^{-1}x^{-1}]\mu_K(dz) = [\sigma(\Theta) \bullet \sigma(\Psi)](x), \]

while the counit is a homomorphism

(4) \[ \phi(\Psi \bullet \Theta) = \int_G \int_{G^2} \Psi(y)\Theta(y^{-1}x)\mu_K(dx)\mu_K(dy) \xrightarrow{x=xy} \int_{G^2} \Psi(y)\Theta(z)\mu_K(dy)\mu_K(dz) = \int_{G^2} \Psi(y)\mu_K(dy) \int_G \Theta(z)\mu_K(dz) = \phi(\Psi) \cdot \phi(\Theta). \]

One of the following standard properties
• $G$ is compact modulo centre (in particular, compact),
• $G$ is perfect (in particular, simple),
• $G$ is second countable and admits a lattice,
• $G$ admits a Gelfand pair (in particular, abelian) [22, Prop 6.1.2]

evaluates that the group $G$ is unimodular. We finish with the following technical fact, useful as a unimodularity criterion, which we will use later in Theorem 6.6:

**Proposition 1.2.** Consider a compact open subgroup $H$ of $G$ and $x \in G$. Then

$$\Delta(x) \cdot |H : H \cap x^{-1}Hx| = |H : H \cap xHx^{-1}|.$$ 

**Proof.** Since $\mu(H) = \mu_K(H)$ is finite, it suffices to observe that $\Delta(x)\mu(H) = \mu(Hx) = \mu(x^{-1}Hx) = \frac{|x^{-1}Hx : H \cap x^{-1}Hx|}{|H : H \cap x^{-1}Hx|} \cdot \mu(H) = \frac{|H : H \cap xHx^{-1}|}{|H : H \cap x^{-1}Hx|} \cdot \mu(H).$ 

\[\square\]

## 2. Category of Smooth Representations

We study representations of a locally compact totally disconnected topological group $G$ over a field $F$. A representation $(\pi, V)$ of $G$ is called smooth if for all $v \in V$ there exists a compact open subgroup $K_v$ of $G$ such that $\pi(k)v = v$ for all $k \in K_v$. We denote the abelian category of all smooth representations of $G$ by $\mathcal{M}(G)$.

Fix a closed central subgroup $A \leq G$, which could be trivial. We want to study $A$-semisimple smooth representations of $G$. A simple representation of $A$ is just a simple $F$-representation of the group algebra $FA$. Hence, it is determined by a field extension $\mathbb{F} \supseteq F$ and a character $\chi : A \to \mathbb{F}^\times$ such that $\widehat{\mathbb{F}}$ is generated as an $A$-algebra by the image of $\chi$. We denote this representation by $\widehat{\mathbb{F}}\chi$ and the set of such characters by $\text{Irr}(\mathbb{F}A)$.

**Definition 2.1.** An $A$-semisimple smooth representation of $G$ is a smooth representation $(\pi, V)$ which is semisimple as a representation of $A$. By $\mathcal{M}_A(G)$ we denote the abelian category of $A$-semisimple smooth representations of $G$. For each character $\chi \in \text{Irr}(\mathbb{F}A)$ we denote by $\mathcal{M}_{A,\chi}(G)$ the full subcategory $\mathcal{M}_A(G)$ of those representations that are direct sums of $\widehat{\mathbb{F}}\chi$ as representations of $A$.

Now let $H$ be a closed subgroup of $G$ with $A \leq H$. Then $H$ is also locally compact and totally disconnected. There are several ways of inducing a representation from $H$ to $G$. We quickly recall them.

Let $(\sigma, W) \in \mathcal{M}_A(H)$. Consider the $\mathbb{F}$-vector space $\widehat{W}$ of all $H$-equivariant functions $f : G \to W$. Equivariance means that

(i) $f(hg) = \sigma(h)f(g)$, for all $h \in H$ and $g \in G$.

Consider the $\mathbb{F}$-vector subspace $\widehat{W} \subseteq \widehat{V}$ of all “smooth” functions, i.e.,

(ii) $f \in \widehat{W}$ if and only if there exists a compact open subgroup $K_f$ of $G$ such that $f(gk) = f(g)$, for all $g \in G$ and $k \in K_f$.

Consider the homomorphism $\rho : G \to \text{Aut}_F(\widehat{W})$ given by $[\rho(g)f](g') = f(g'g)$ for $g, g' \in G$ and $f \in \widehat{W}$. If $f \in \widehat{W}$ and $a \in A$, then $[\rho(a)f](g) = f(ga) = f(ag) = \sigma(a)f(g)$ for all $g \in G$. Writing $W = \bigoplus_i W_i$ as a direct sum of simple $A$-modules $W_i = \widehat{\mathbb{F}}\chi_i$, we can present $f = \sum_i f_i$ as a sum of $A$-equivariant smooth functions

$f_i : G \to W_i$ so that $[\rho(a)f](g) = \sum_i \sigma(a)f_i(g) = \sum_i [\chi_i(a)f_i](g)$. This proves
that $(\rho, \widehat{W})$ is $A$-semisimple (but not smooth). Its submodule $(\rho, \widehat{W})$ is smooth and also $A$-semisimple, hence it is in $\mathcal{M}_A(G)$. Following standard conventions in the literature, we call the pair $(\rho, \widehat{W})$ the representation of $G$ smoothly induced by $\sigma$ and denote it $\text{Ind}_G^H(\sigma)$.

If we restrict our attention to the subspace of $\widehat{W}$ of compactly supported modulo $H$ functions, we obtain another representation of $G$ called compactly induced and denoted by $c - \text{Ind}_H^G(\sigma)$. The $FH$-module $\mathbb{F}G \otimes W$ becomes an $FG$-module by setting $g(g' \otimes w) = gg' \otimes w$ for $g, g' \in G, w \in W$. We call this representation of $G$ algebraically induced and denote it $a - \text{Ind}_H^G(\sigma)$. It is $A$-semisimple but not, in general, smooth.

Let $H$ be open, $A \leq H$. This guarantees smoothness of $a - \text{Ind}_H^G(\sigma)$. Now consider the map $\varphi : \mathbb{F}G \otimes W \to \text{Fun}_H(GH, hW)$ given by

$$g \otimes w \mapsto (f : gh^{-1} \mapsto hw), \quad g \in G, h \in H, w \in W.$$ 

As $H$ is open, $\varphi$ is an isomorphism from $a - \text{Ind}_H^G(\sigma)$ to $c - \text{Ind}_H^G(\sigma)$. Let us summarise the observations above:

**Lemma 2.2.** Let $G$ be a locally compact totally disconnected group. Suppose $H \geq A$ is a subgroup of $G$, closed and compact modulo $A$. The following hold:

1. $\text{Ind}_H^G$ and $c - \text{Ind}_H^G$ define functors from $\mathcal{M}_A(H)$ (or $\mathcal{M}_{A,\chi}(H)$) to $\mathcal{M}_A(G)$ ($\mathcal{M}_{A,\chi}(G)$ correspondingly).
2. In the case when $H$ is also open, $a - \text{Ind}_H^G$ also defines a functor from $\mathcal{M}_A(H)$ (or $\mathcal{M}_{A,\chi}(H)$) to $\mathcal{M}_A(G)$ ($\mathcal{M}_{A,\chi}(G)$ correspondingly).

**Lemma 2.3.** Let $H$ be a subgroup of $G$, compact modulo $A$. Suppose that the field $\mathbb{F}$ is $H/A$-ordinary. Then the categories $\mathcal{M}_{A,\chi}(H)$ and $\mathcal{M}_A(H)$ are semisimple.

**Proof.** Let $V \in \mathcal{M}_A(H)$. Then by definition $V$ is $A$-semisimple and hence can be decomposed as $V = \bigoplus_{\chi} V_\chi$ with $V_\chi = \{v \in V \mid av = \chi(a)v\}$ for all $a \in A$. In other words, $\mathcal{M}_A(H) = \bigoplus_{\chi} \mathcal{M}_{A,\chi}(H)$, so it is enough to prove the statement for $\mathcal{M}_{A,\chi}(H)$.

Let $V \in \mathcal{M}_{A,\chi}(H)$. Then $V$ is an $\mathbb{F}$-vector space with an $\mathbb{F}$-linear $H$-action. Let $v \in V$. By smoothness there exists a compact open subgroup $K_v$ of $H$ such that $kv = v$ for all $k \in K_v$. Let $V' := \langle Hv \rangle_H$. Clearly, $H/\AK_v$ is both compact and discrete. Hence, $H/\AK_v$ is finite and $V'$ is a finite dimensional $\mathbb{F}$-subspace of $V$.

We want to show that $V$ is $H$-semisimple. It suffices to find a direct $\mathbb{F}H$-complement in $V$ of a finite dimensional $H$-submodule $W$. Pick an $\mathbb{F}$-linear projection $p : V \to W$. Since $W$ is finite dimensional, we can write $p(v) = \sum_{i=1}^n p_i(v)e_i$ for some basis $e_1, \ldots, e_n$ of $W$ and some linear functions $p_i : V \to \mathbb{F}$.

Pick a section $x \mapsto \hat{x}$ of the quotient homomorphism $H \to H/A$. Let $\mu = \mu_{H/A}$ be a Haar measure on $H/A$ with values in $\mathbb{F}$. Define $\hat{\mu} : V \to W$ by

$$\hat{\mu}(v) := \int_{H/A} \hat{x}^{-1}p(\hat{x}v)\mu(dx).$$
The map $\tilde{p}$ is well-defined: write $\tilde{x}^{-1}p(\tilde{x}v) = \sum_i \sum_j \psi_{ij}(x^{-1})\phi_j(x)e_i$ for some $\psi_{ij}, \phi_j \in C^\infty(H, \mathbb{F})$, then integrate the functions.

Clearly, $\tilde{p}$ is a well-defined $\mathbb{F}$-linear projection. Let us verify that $\tilde{p}(yv) = y\tilde{p}(v)$ for all $y \in H, v \in V$. Let $\Psi = yA \in H/A$. For the standard argument we need a change of variable $z = x\Psi$. The group $H/A$ is compact, hence, unimodular and $\mu(dz) = \mu(dx)$. Then $x\Psi = a_x\tilde{z}$ for some element $a_x \in A$ depending on $x$ (we think that $y$ is fixed). Furthermore, $x^{-1} = a_x^{-1}y\tilde{z}^{-1}$ and

$$\tilde{p}(yv) = \int_{H/A} \tilde{x}^{-1}p(x\Psi v)\mu(dx) = \int_{H/A} a_x^{-1}y\tilde{z}^{-1}p(a_x\tilde{z}v)\mu(dz) = y\tilde{p}(v).$$

The last equality holds because $a_x$ acts via the scalar $\gamma(a_x) \in \mathbb{F}$ and $p$ is $\mathbb{F}$-linear. This yields a decomposition $V = W \oplus \ker(\tilde{p})$, finishing the proof.

If $A$ is trivial and hence $H$ is compact, then the category $\mathcal{M}(H)$ of smooth representations of $H$ is semisimple.

The Hecke algebra $\mathcal{H} = \mathcal{H}(G, F, \mu_K)$, defined in the last section is a $G - G$-bimodule, smooth on both left and right. We turn these into two commuting with each other structures of a left $G$-module:

$$\tilde{x}^\psi(y) = \psi(\tilde{x}^{-1}y), \quad \psi^\tilde{x}(y) = \psi(y).$$

Let $(M, \ast)$ be an $\mathcal{H}$-module. $M$ is called smooth if $\mathcal{H} \ast M = M$. This is equivalent to saying that for every $m \in M$ there exists a compact open subgroup $K$ of $G$ such that $\Lambda_K \ast m = m$. All smooth $\mathcal{H}$-modules form a category which we denote by $\mathcal{M}(\mathcal{H})$.

**Proposition 2.4.** (cf. [4], 1.4.2) Suppose $\mathcal{H}$ exists (which follows from existence of a compact open subgroup $H$ such that the field $\mathbb{F}$ is $H$-ordinary). Then the categories $\mathcal{M}(G)$ and $\mathcal{M}(\mathcal{H})$ are equivalent.

**Proof.** We start by defining a functor $\mathcal{F} : \mathcal{M}(G) \to \mathcal{M}(\mathcal{H})$. Fix $(\pi, V) \in \text{Ob}(\mathcal{M}(G))$. The action

$$\Theta \cdot v = \pi(\Theta)v := \int_G \Theta(g)\pi(g)v\mu(dg), \quad \Theta \in \mathcal{M}(\mathcal{H}), v \in V$$

gives $V$ the structure of a (left) smooth $\mathcal{H}$-module:

$$(\Psi \ast \Theta) \cdot v = \int_{G^2} \Psi(y)\Theta(y^{-1}x)\pi(x)v\mu(dx)\mu(dy) = \Psi \cdot (\Theta \cdot v).$$

We denote this module by $\mathcal{F}(V)$.

Let $(\pi, V), (\pi', V') \in \mathcal{M}(G)$ and $\phi \in \text{Hom}(V, V')$. Take a compact open subgroup $K$ which fixes $v \in V$ and $\Theta \in \mathcal{H}$. Then the integral above is nothing but

$$\pi(\Theta)v = \mu(K) \sum_{gK \in G/K} \Theta(g)\pi(g)v.$$
Using this we calculate
\[ \phi(\pi(\Theta)v) = \phi \left( \mu(K) \sum_{gK \in G/K} \Theta(g)\pi(g)v \right) = \mu(K) \sum_{g \in G/K} \Theta(g)\phi(\pi(g))v = \mu(K) \sum_{gK \in G/K} \Theta(g)\pi'(g)\phi(v) = \pi'(\Theta)\phi(v). \]

In particular, every \( \phi \in \text{Hom}_{\mathcal{M}(G)}(V, V') \) is also an element of \( \text{Hom}_{\mathcal{M}(\mathcal{H})}(\mathcal{F}(V), \mathcal{F}(V')) \). Thus we have defined the functor \( \mathcal{F} : \mathcal{M}(G) \to \mathcal{M}(\mathcal{H}) \). For the quasi-inverse, take \( M \in \mathcal{M}(\mathcal{H}), m \in M \) and a compact open subgroup \( K \) of \( G \) such that \( \Lambda_K * m = m \).

Define a \( G \)-action in the following way:
\[ g * m = \Lambda_gK * m. \]

This action gives \( M \) the structure of a smooth \( G \)-module \( \mathbb{R} \).

Using the definition of the module action above, it is easy to check that any \( \psi \in \text{Hom}_{\mathcal{M}(\mathcal{H})}(M, M') \) is also an element of \( \text{Hom}_{\mathcal{M}(G)}(\mathcal{G}(M), \mathcal{G}(M')) \). This defines a functor \( \mathcal{G} : \mathcal{M}(\mathcal{H}) \to \mathcal{M}(G) \).

It is left to check that \( \mathcal{G} \) is indeed quasi-inverse to \( \mathcal{F} \). Fix \( (\pi, V) \in \mathcal{M}(G) \) and \( M \in \mathcal{M}(\mathcal{H}) \). We need the following equalities to hold:
1. \( g \cdot v = g * v \) for \( v \in V, g \in G \).
2. \( \Theta * m = \Theta \cdot m \) for \( m \in M, \Theta \in \mathcal{H} \).

Now, for a compact open subgroup \( K \) of \( G \) which fixes \( v \) under \( \cdot \) we have
\[ g * v = \Lambda_gK * v = \int_G \Lambda_gK(x)\pi(x)v \mu(dx) = \mu(K)^{-1} \int_{gK} \pi(x)v \mu(dx) = \mu(K)^{-1} \int_K \pi(gx)\mu(dx) = \mu(K)^{-1} \int_K \pi(g)\pi(x)v \mu(dx) = \pi(g)v = g \cdot v. \]

This settles (1). To prove (2) we similarly pick a compact open subgroup \( K \) such that \( \Lambda_K * m = m \). Observe that \( \Lambda_H * m = m \) for any compact open subgroup \( H \leq K \) since \( \Lambda_H * \Lambda_K = \Lambda_K \). Now we can represent an arbitrary function \( \Theta \) as a linear combination of functions \( \Lambda_gH \) where \( \Lambda_H * m = m \). Thus, it suffices to verify (2) for such functions:
\[ \Lambda_gH \cdot m = \int_G \Lambda_gH(x)\pi(x)m \mu(dx) \overset{\text{by } \mu} = \mu(H)^{-1} \int_H \pi(gy)m \mu(dy) = \mu(H)^{-1} \pi(g)m \Lambda_gH \cdot m = \pi(g)m = \Lambda_gH * m. \]

Now we go back to our initial object of interest – the category \( \mathcal{M}_A(G) \). Using the functor \( \mathcal{F} \) from Proposition 2.3 we define \( \mathcal{M}_{A,\lambda}(\mathcal{H}) := \mathcal{F}(\mathcal{M}_{A,\lambda}(G)), \mathcal{M}_{A}(\mathcal{H}) := \mathcal{F}(\mathcal{M}_A(G)) \). The following theorem is a tautology but we state it because it is an important stepping stone.

**Theorem 2.5.** If \( \mathcal{H} \) exists, then \( \mathcal{M}_A(G) \) is equivalent to \( \mathcal{M}_A(\mathcal{H}) \).
Pick a module $V \in \mathcal{M}(G)$. Its (skew) coinvariants $V_{A,\chi}$ is a module in $\mathcal{M}_{A,\chi}(G)$:

$$V_{A,\chi} := \hat{F} \otimes_{F A} V,$$

where the ring homomorphism is $\chi : FA \to \hat{F}$. Observe that if $V \in \mathcal{M}_{A,\chi}(G)$, then $V$ is naturally a vector space over $\hat{F}$ and $V$ and $V_{A,\chi}$ are naturally isomorphic. Furthermore, the skew coinvariants define a functor $\mathcal{M}(G) \to \mathcal{M}_{A,\chi}(G)$, $V \mapsto V_{A,\chi}$, $\varphi \mapsto \varphi_{A,\chi} = 1 \otimes \varphi$.

**Lemma 2.6.** The category $\mathcal{M}_{A,\chi}(\mathcal{H})$ has enough projectives.

**Proof.** For $N \in \mathcal{M}_{A,\chi}(\mathcal{H})$, $n \in N$ we can define a map $\varphi : \mathcal{H} \Lambda_H \to N$ by $\varphi(\Theta \Lambda_H) = \Theta \ast n$ once we choose a compact open subgroup $H$ such that $\Lambda_H \ast n = n$. The corresponding map $\varphi_{A,\chi} : (\mathcal{H} \Lambda_H)_{A,\chi} \to N$ has $n$ in its image.

It remains to observe that $(\mathcal{H} \Lambda_H)_{A,\chi}$ is projective. The module $\mathcal{H} \Lambda_H$ is projective in $\mathcal{M}(\mathcal{H})$ [20 I.5.2]. Hence, $(\mathcal{H} \Lambda_H)_{A,\chi}$ is projective in $\mathcal{M}_{A,\chi}(\mathcal{H})$ because a functor (coinvariants in our case), left adjoint to a right exact functor (the embedding in our case) takes projective objects to projective objects. \qed

**Corollary 2.7.** If $\mathcal{H}$ exists, the categories $\mathcal{M}_{A,\chi}(G)$ and $\mathcal{M}_A(G)$ have enough projectives.

**Proof.** The statement about $\mathcal{M}_{A,\chi}(G)$ is immediate. The category $\mathcal{M}_A(G)$ is a direct sum $\oplus \mathcal{M}_{A,\chi}(G)$, hence, $\mathcal{M}_A(G)$ also has enough projectives. \qed

3. Projective Dimension

Let us now investigate the projective dimension of the category $\mathcal{M}_A(G)$. As we have seen in the previous section, induction and compact induction are useful functors.

**Lemma 3.1.** Let $G$ be a locally compact totally disconnected group. Suppose $H \cong A$ is a subgroup of $G$, closed and compact modulo $A$. Then $\text{Ind}^G_H$ takes injective objects to injective objects. If $H$ is open then $c - \text{Ind}^G_H$ takes projective objects to projective objects.

Moreover, if the field $F$ is $H/A$-ordinary and $(\sigma, W) \in \mathcal{M}_A(H)$, then $\text{Ind}_H^G(\sigma)$ is an injective object and $c - \text{Ind}_H^G(\sigma)$ is a projective object, as soon as $H$ is open.

**Proof.** Frobenius reciprocity for $\text{Ind}_H^G$ tells us that it is right adjoint to $\text{Res}_H^G$ and since any right adjoint to a left exact functor takes injective objects to injective objects. Similarly, by Frobenius reciprocity for compact induction from open $H$, $c - \text{Ind}_H^G$ is left adjoint to the restriction functor $\text{Res}_H^G$, which is exact. Any such functor takes projective objects to projective objects.

In the case when $F$ is $H/A$-ordinary, $\mathcal{M}_A(H)$ is semisimple, hence $(\sigma, W) \in \mathcal{M}_A(H)$ is a semisimple $H$-module. In other words, $W$ is both injective and projective. We are done by the first part. \qed

Observe that $a - \text{Ind}_H^G \cong c - \text{Ind}_H^G$ for an open $H$. Therefore, we can deduce the following:
Corollary 3.2. Let $G$ be a locally compact totally disconnected group. Suppose $H \geq A$ is a subgroup of $G$, open and compact modulo $A$. Further suppose that the field $\mathbb{F}$ is $H/A$-ordinary. If $(\sigma, W)$ is a representation in $\mathcal{M}_A(H)$, then $\mathbb{F}G \otimes W$ is a projective object in $\mathcal{M}_A(G)$. The statement is also true if we replace $\mathcal{M}_A(H)$ with $\mathcal{M}_{A, \chi}(H)$.

If $A$ is trivial, Corollary 3.2 yields that smooth representations of $G$ algebraically induced from a compact open subgroup are projective.

Lemma 3.3. Let $G$ be a locally compact totally disconnected group. Suppose $\mathbb{F}$ is the trivial representation of $G$ and

$$0 \to P_n \to P_{n-1} \to \cdots \to P_0 \to \mathbb{F} \to 0$$

is a projective resolution of $\mathbb{F}$ in $\mathcal{M}_A(G)$. Let $(\pi, V) \in \mathcal{M}_A(G)$, not necessarily finite dimensional. Then

$$0 \to P_n \otimes V \to P_{n-1} \otimes V \to \cdots \to P_0 \otimes V \to V \to 0$$

is a projective resolution for $V$ in $\mathcal{M}_A(G)$. The statement is also true if we replace $\mathcal{M}_A(G)$ with $\mathcal{M}_{A, \chi}(G)$.

Proof. We will prove the statement for $\mathcal{M}_A(G)$, but the proof is the same for $\mathcal{M}_{A, \chi}(G)$. For the result to hold, it is enough to show that $P_i \otimes V$ is a projective object in $\mathcal{M}_A(G)$ for all $i = 1, \ldots, n$.

Observe that $\text{Hom}_{\mathcal{M}_A(G)}(P_i \otimes V, -) \cong \text{Hom}_{\mathcal{M}_A(G)}(P_i, \text{Hom}_{\mathbb{F}}(V, -))$: to every $\alpha \in \text{Hom}_{\mathcal{M}_A(G)}(P_i \otimes V, W)$ we associate $\beta \in \text{Hom}_{\mathcal{M}_A(G)}(P_i, \text{Hom}_{\mathbb{F}}(V, W))$ defined by $\beta : p_i \mapsto (\gamma : v \mapsto \alpha(p_i \otimes v))$ for $p_i \in P_i, v \in V$. Conversely, to every $\beta : p_i \mapsto (\gamma : v \mapsto w)$ we associate $\alpha : p_i \otimes v \mapsto \beta(p_i)(v)$ for $p_i \in P_i, v \in V, w \in W$.

Since $P_i$ is projective, the functor $\text{Hom}_{\mathcal{M}_A(G)}(P_i, -)$ is exact. As $V$ is a free $\mathbb{F}$-module, $\text{Hom}_{\mathbb{F}}(V, -)$ is also exact. The composition of two exact functors is exact, so $\text{Hom}_{\mathcal{M}_A(G)}(P_i \otimes V, -)$ is exact and $P_i \otimes V$ is projective.

Let $X_n = (X_n)$, for $n = 0, 1, \ldots$, be a simplicial set [12, Ch. 1]. We say that $G$ acts on $X_n$ if $G$ acts on each set $X_n$ and the action commutes with the face maps $\partial(f)$. We are finally ready for the main theorem of this section.

Theorem 3.4. Let $G$ be a locally compact totally disconnected group, $A$ its closed central subgroup. Suppose $G$ acts on a simplicial set $X_n$, such that its geometric realisation $|X|$ is contractible of dimension $n$ and $A$ acts trivially on $X_n$. Suppose further that the stabiliser $G_x$ of any $x \in X_n$ is open and compact modulo $A$. If the field $\mathbb{F}$ is $G_x/A$-ordinary for any $x \in X_n$, then

$$\text{proj. dim}(\mathcal{M}_{A, \chi}(G)) \leq n \quad \text{and} \quad \text{proj. dim}(\mathcal{M}_A(G)) \leq n.$$ 

Proof. Recall that the projective dimension of an object is the minimal length of a resolution by projective objects. Since $\mathcal{M}_{A, \chi}(G)$ and $\mathcal{M}_A(G)$ have enough projectives, projective resolutions exist, so we can talk about the projective dimension of the categories.

Denote by $X_i$ the $\mathbb{F}$-vector space formally spanned by the elements of $X_{(i)}$, the set of non-degenerate simplices in $X_i$. Since $G$ acts on $X_n$, it also acts on $X_i$ and thus $X_i$ is an $\mathbb{F}G$-module. Consider the chain complex

$$G : \quad X_n \xrightarrow{d_0} X_{n-1} \xrightarrow{d_{n-1}} \cdots \xrightarrow{d_1} X_0.$$
where \(d_\ast\) denote the standard boundary operator (cf. Eq. (6), Section [3]). Since \(|\mathcal{X}|\) is contractible, \(\mathcal{C}\) is acyclic, so all homology groups are trivial except \(H_0(\mathcal{C}) \cong \mathbb{F}\). This yields the exact sequence:

\[
0 \to X_n \xrightarrow{d_n} X_{n-1} \xrightarrow{d_{n-1}} \cdots \xrightarrow{d_1} X_0 \to \mathbb{F} \to 0.
\]

Let \(\mathbb{F}[\sigma]\) be the \(\mathbb{F}\)-vector space spanned by \(\sigma \in \mathcal{X}(i)\). The stabiliser \(G_\sigma\) acts on \(\sigma\) by either preserving or reversing its orientation. Extending this action linearly we get an action of \(G_\sigma\) on \(\mathbb{F}[\sigma]\). Consider a homomorphism \(\rho : G_\sigma \to \text{Aut}_\mathbb{F}(\mathbb{F}[\sigma])\). As \(A\) acts trivially on \(\mathcal{X}\), it also acts trivially on \(\mathbb{F}[\sigma]\), so \((\rho, \mathbb{F}[\sigma]) \in \mathcal{M}_{A,1}(G)\). Since \(G_\sigma\) is open and compact modulo \(A\), \(\mathbb{F}G \otimes \mathbb{F}[\sigma]\) is a projective object in \(\mathcal{M}_{A,1}(G)\) by Corollary 3.2.

As a sum of projective objects \(\sum_{\sigma \in \mathcal{X}(i)} \mathbb{F}G \otimes \mathbb{F}[\sigma]\) is also projective. We have a \(G\)-module isomorphism

\[
\sum_{\sigma \in \mathcal{X}(i)} \mathbb{F}G \otimes \mathbb{F}[\sigma] \cong X_i, \quad g \otimes \alpha \sigma \mapsto g \alpha \sigma
\]

so that sequence (5) is a projective resolution of \(\mathbb{F}\) in \(\mathcal{M}_{A,1}(G)\).

Let \((\pi, V) \in \mathcal{M}_{A,\chi}(G)\). By Lemma \[3.3\]

\[
X_n \otimes V \to X_{n-1} \otimes V \to \cdots \to X_0 \otimes V \to V \to 0
\]

is a projective resolution of \(V\) of length at most \(n\). This concludes the proof for \(\mathcal{M}_{A,\chi}(G)\). Since \(\mathcal{M}_A(G) = \otimes_\chi \mathcal{M}_{A,\chi}(G)\), we get \(\text{proj.dim}(\mathcal{M}_A(G)) \leq n\). \(\square\)

**Example 3.5.** Let \(G = \text{GL}_n(\mathbb{K})\), where \(\mathbb{K}\) is a non-Archimedean local field and centre \(Z(G) = \mathbb{K}^\times\). Let \(\pi\) be a uniformizer in \(\mathbb{K}\). Set \(A = \langle \pi^n \rangle\) as our closed central subgroup. As observed by Bernstein [1, Th. 30], the action of \(G\) on its Bruhat-Tits building implies that \(\text{proj.dim}(\mathcal{M}(\text{PGL}_n(\mathbb{K}))) \leq n\). Our Theorem \[3.4\] gives not only this result but also a subtler result that \(\text{proj.dim}(\mathcal{M}_A(\text{GL}_n(\mathbb{K}))) \leq n\).

4. **Cosheaves**

Let \(\mathcal{X}_\ast = (\mathcal{X}_n)\) be a simplicial set, \(|\mathcal{X}|\) its geometric realisation. We follow Gelfand and Manin [12, Ch. 1] with all notation and terminology except that we use the term *sheaf* for a cohomological coefficient system and *cosheaf* for a homological coefficient system. By default all our sheaves and cosheaves are with coefficients in \(\mathbb{F}\)-vector spaces.

Our change of terminology is justified not only by its brevity: a sheaf \(\mathcal{F}\) on \(\mathcal{X}_\ast\) (cf. Definition [12]) determines a constructible sheaf \(|\mathcal{F}|\) on the geometric realisation \(|\mathcal{X}|\). Recall a canonical bijection

\[
\hat{\tau} : \bigsqcup_n \Delta_n \times \mathcal{X}(n) \to |\mathcal{X}|
\]

where \(\mathcal{X}(n)\) is the set of non-degenerate \(n\)-simplices and \(\Delta_n = \{(\alpha_0, \ldots, \alpha_n) \in \mathbb{R}^{n+1}_{>0} \mid \sum \alpha_k = 1\}\) is the abstract \(n\)-dimensional simplex. The constructible sheaf \(|\mathcal{F}|\) has the following stalk at a point \(p \in |\mathcal{X}|\):

\[|\mathcal{F}|_p = \mathcal{F}_p\]

while the restrictions are determined by the linear (sheaf on \(\mathcal{X}_\ast\)) structure maps \(\mathcal{F}(f, x) : \mathcal{F}|_{\mathcal{X}(f)x} \to \mathcal{F}_x\), where \(f : [m] \to [n]\) is nondecreasing map, \([n] = \{0, 1, \ldots, n\}\).
defines a constructible cosheaf \( \mathcal{C} \) on \( \mathcal{X} \).

Now we consider a continuous action of \( G \) on the simplicial set \( \mathcal{X} \). The continuity condition on the action means that the stabiliser \( G_x \) of any simplex \( x \in \mathcal{X} \) is open in \( G \). We assume that the central subgroup \( A \) acts trivially on \( \mathcal{X} \).

**Definition 4.1.** An **equivariant cosheaf** is a cosheaf \( \mathcal{C} \) with an additional data: a linear map \( g_x = g(C)_x : C_x \to C_{g_x} \) for any \( g \in G \) and any simplex \( x \). This data satisfies three axioms:

(i) \( s_{gh} \circ h_x = (gh)_x \) for any \( g, h \in G \) and a simplex \( x \).

(ii) \( C_x \) is a smooth representation of \( G_x \) for any simplex \( x \).

(iii) The square \( \begin{array}{ccc}
C(f)_x & \xrightarrow{\psi(f)_x} & C(g)_x \\
\downarrow C(f,x) & & \downarrow C(g,x) \\
C(\mathcal{X}(f))_x & \xrightarrow{\mathcal{X}(\psi(f))_x} & C(\mathcal{X}(g))_x
\end{array} \) is commutative for all \( g \in G \), simplices \( x \in \mathcal{X}_n \) and nondecreasing maps \( f : [m] \to [n] \).

A morphism \( \psi : \mathcal{C} \to \mathcal{D} \) of equivariant cosheaves is a system of linear maps \( \psi_x : C_x \to D_x \), commuting with actions and corestrictions, i.e., the squares \( \begin{array}{ccc}
C_x & \xrightarrow{\psi_x} & D_x \\
\downarrow C(f,x) & & \downarrow D(f,x) \\
C(\mathcal{X}(f))_x & \xrightarrow{\mathcal{X}(\psi(f))_x} & D(\mathcal{X}(f))_x
\end{array} \) are commutative for all \( g \in G \), \( x \in \mathcal{X}_n \) and nondecreasing maps \( f : [m] \to [n] \).

We denote the category of equivariant cosheaves by \( \text{Csh}_G(\mathcal{X}_\bullet) \). It is an abelian category \([21]\): kernels and cokernels can be computed simplicewise. Another abelian category of interest is the category \( \text{Sh}_G(\mathcal{X}_\bullet) \) of equivariant sheaves. For the sake of completeness we give its full definition.

**Definition 4.2.** An **equivariant sheaf** is a sheaf \( \mathcal{F} \) with an additional data: a linear map \( g_x = g(\mathcal{F})_x : \mathcal{F}_x \to \mathcal{F}_{g_x} \) for any \( g \in G \) and any simplex \( x \). This data satisfies three axioms:

(i) \( s_{gh} \circ h_x = (gh)_x \) for any \( g, h \in G \) and a simplex \( x \).

(ii) \( \mathcal{F}_x \) is a smooth representation of \( G_x \) for any simplex \( x \).

(iii) The square \( \begin{array}{ccc}
\mathcal{F}(f)_x & \xrightarrow{\psi(f)_x} & \mathcal{F}(g)_x \\
\downarrow \mathcal{F}(f,x) & & \downarrow \mathcal{F}(g,x) \\
\mathcal{F}(\mathcal{X}(f))_x & \xrightarrow{\mathcal{X}(\psi(f))_x} & \mathcal{F}(\mathcal{X}(g))_x
\end{array} \) is commutative for all \( g \in G \), simplices \( x \in \mathcal{X}_n \) and nondecreasing maps \( f : [m] \to [n] \).

A morphism \( \psi : \mathcal{F} \to \mathcal{E} \) of equivariant sheaves is a system of linear maps \( \psi_x : \mathcal{F}_x \to \mathcal{E}_x \), commuting with actions and restrictions, i.e., the squares \( \begin{array}{ccc}
\mathcal{F}_x & \xrightarrow{\psi_x} & \mathcal{E}_x \\
\downarrow \mathcal{F}(f,x) & & \downarrow \mathcal{E}(f,x) \\
\mathcal{F}(\mathcal{X}(f))_x & \xrightarrow{\mathcal{X}(\psi(f))_x} & \mathcal{E}(\mathcal{X}(f))_x
\end{array} \) are commutative for all \( g \in G \), \( x \in \mathcal{X}_n \) and nondecreasing maps \( f : [m] \to [n] \).
are commutative for all \( g \in G, \ x \in \mathcal{X}_n \) and nondecreasing maps \( f : [m] \to [n] \).

We say that an equivariant cosheaf \( \mathcal{C} \) (sheaf \( \mathcal{F} \)) is discrete if the stabiliser \( G_x \) of any simplex \( x \) acts on \( G_x \) (correspondingly \( \mathcal{F}_x \)) through a discrete quotient, i.e. the kernel of this representation is an open subgroup of \( G_x \). The full subcategories of discrete equivariant cosheaves \( \text{Csh}_G(\mathcal{X}_*) \) or discrete equivariant sheaves \( \text{Sh}_G(\mathcal{X}_*) \) are abelian categories.

Other full subcategories are \( A \)-semisimple (co)sheaves, i.e., those (co)sheaves where each \( \mathcal{F}_x \) (correspondingly \( G_x \)) is \( A \)-semisimple. There is a further version of \( A \)-semisimple (co)sheaves with a fixed character \( \chi \). Hence, we have six categories of equivariant cosheaves (and similarly sheaves):

\[
\begin{array}{cccc}
\text{Csh}_G(\mathcal{X}_*) & \xleftarrow{=} & \text{Csh}_{G,A}(\mathcal{X}_*) & \xrightarrow{=} \text{Csh}_{G,A,\chi}(\mathcal{X}_*) \\
\uparrow \text{Id} & & \uparrow \text{Id} & \uparrow \text{Id} \\
\text{Csh}_{\hat{G}}(\mathcal{X}_*) & \xleftarrow{=} & \text{Csh}_{\hat{G},A}(\mathcal{X}_*) & \xrightarrow{=} \text{Csh}_{\hat{G},A,\chi}(\mathcal{X}_*)
\end{array}
\]

If \((\rho, V)\) is a smooth representation of \( G \), we can associate the trivial cosheaf \( V \) and the trivial sheaf \( \underline{V} \) to it. We define

\[
\underline{V}_x = V_x := V, \quad V(f, x) := \text{Id}_V, \quad \underline{V}(f, x) := \text{Id}_V, \quad g_x := \rho(g)
\]

for all \( g \in G, \ x \in \mathcal{X}_n \) and nondecreasing maps \( f : [m] \to [n] \). The trivial cosheaf \( V \) is discrete (\( A \)-semisimple) if and only if \( V \) is discrete (\( A \)-semisimple) if and only if the trivial sheaf \( \underline{V} \) is discrete (\( A \)-semisimple).

We need to work a bit harder to construct more interesting discrete sheaves and cosheaves. With this aim in mind we propose the following definition.

**Definition 4.3.** A system of subgroups \( \mathcal{G} \) of \( G \) acting on \( \mathcal{X}_* \) is a datum assigning a subgroup \( \mathcal{G}_x \) of the simplex stabiliser \( G_x \) to each simplex \( x \in \mathcal{X}_n \). The datum needs to be \( G \)-equivariant, i.e., \( g \mathcal{G}_x g^{-1} = \mathcal{G}_{gx} \) for all \( g \in G \) and \( x \in \mathcal{X}_n \). The following adjectives will be applied to a system of subgroups \( \mathcal{G} \):

- The system is open if \( \mathcal{G}_x \) is open in \( G_x \) for all \( x \).
- The system is closed if \( \mathcal{G}_x \) is closed in \( G_x \) for all \( x \).
- The system is cofinite if the index of \( \mathcal{G}_x \) in \( G_x \) is finite for all \( x \).
- The system is compact modulo \( A \) if \( \mathcal{G}_x \) is compact modulo \( A \) for all \( x \).
- The system is contravariant if \( \mathcal{G}_{X(f),x} \subseteq \mathcal{G}_x \) for all \( x \in \mathcal{X}_n \) and nondecreasing maps \( f : [m] \to [n] \).
- The system is covariant if \( \mathcal{G}_{X(f),x} \supseteq \mathcal{G}_x \) for all \( x \in \mathcal{X}_n \) and nondecreasing maps \( f : [m] \to [n] \).

Observe that the \( G \)-equivariance implies that \( \mathcal{G}_x \) is a normal subgroup of \( G_x \).

We have a minor moral dilemma which system we should call covariant and which contravariant. We resolve this dilemma by calling covariant the system of stabilisers \( \mathcal{G}_x := G_x \) for a label-preserving action of \( G \) on a building. We can construct interesting sheaves and cosheaves by taking invariants and coinvariants with respect to a system of subgroups.

**Proposition 4.4.** Let \( \mathcal{G} \) be a system of subgroups and \((\rho, V)\) a smooth \( G \)-representation. The following statements hold:
(1) If \( G \) is contravariant, then the invariants \( V_G^x := V^G_x \) is an equivariant cosheaf and the coinvariants \( V^G_x :={\overset{\sim}{V}_G^x} \) is an equivariant sheaf.

(2) If \( G \) is covariant, then the invariants \( V^G_x := V^G_x \) is an equivariant sheaf and the coinvariants \( V^G_x :={\overset{\sim}{V}_G^x} \) is an equivariant cosheaf.

(3) If, further to (1) or (2), \( G \) is open, then the (co)sheaf is discrete.

(4) If, further to (1) or (2), \( V \) is \( A \)-semisimple (with a fixed character \( \chi \)), then the sheaves \( V^G \), \( V^G_\chi \) and the cosheaves \( V^G \), \( V^G_\chi \) are \( A \)-semisimple (with a fixed character \( \chi \) correspondingly).

**Proof.** One of the invariant spaces \( V^G_x \) and \( V^{G X(f)}_x \) contains the other one. Which contains which depends on whether the system of subgroups is contravariant or covariant. More precisely, a covariant system produces a sheaf, while a contravariant system produces a cosheaf. The action of \( G \) is given by \( \rho \) in both cases: \( g_x := \rho(x) \).

The coinvariant spaces \( V_G_x \) and \( V^{G X(f)}_x \) are connected by a natural surjection. Similarly to invariants, a contravariant system produces a sheaf, while a covariant system produces a cosheaf. The action of \( G \) is again given by \( \rho \).

The last two statements are immediate. \( \square \)

Cosheaves are more suitable than sheaves for studying representations in this simplicial environment. We turn our attention to cosheaves, commenting later on difficulties one faces with sheaves. Let us recall the homology of \( \mathcal{X} \) with coefficients in a cosheaf \( C \) \[12]:

\[ C_n(\mathcal{X}, C) := \left\{ \sum_{x \in \mathcal{X}_n} \alpha_x x \mid \alpha_x \in C_x, \text{ all but finitely many } \alpha_x = 0 \right\}. \]

To define the differential we need the \( i \)-th face maps \( \mathcal{X}(\partial^i_n) \), where \( \partial^i_n : [n-1] \to [n] \) is the unique increasing map, missing the value \( i \):

\[ d_n : C_n(\mathcal{X}, C) \to C_{n-1}(\mathcal{X}, C), \quad d_0 := 0, \]

\[ d_n \left( \sum_{x \in \mathcal{X}_n} \alpha_x x \right) := \sum_{x \in \mathcal{X}_n} \sum_{i=0}^{n} (-1)^i [C(\partial^i_n, x)(\alpha_x)] [[\mathcal{X}(\partial^i_n)(x)] \]

for \( n > 0 \). If the simplicial set \( \mathcal{X} \) is of geometric origin, then a face of a non-degenerate simplex is non-degenerate. In this case we have a subcomplex \((C_n(\mathcal{X}(\star), C), d_n)\) that consists of linear combinations of non-degenerate simplices \( \sum_{x \in \mathcal{X}(\star)} \alpha_x x \). For an open subgroup \( K \subseteq G \) we introduce the full subcategory \( \mathcal{M}(G)^K \) of \( \mathcal{M}(G) \) whose objects are smooth \( G \)-representations generated by their \( K \)-fixed vectors. Also, let \( \mathcal{M}(G)^\circ \) be the union of various \( \mathcal{M}(G)^K \). Its objects are those smooth representations that are generated by \( K \)-fixed vectors for some open subgroup \( K \subseteq G \). Inside them we have the corresponding \( A \)-semisimple categories

\[ \mathcal{M}_A(G)^K, \mathcal{M}_A(G)^\circ, \mathcal{M}_{A, \chi}(G)^K \text{ and } \mathcal{M}_{A, \chi}(G)^\circ. \]

**Proposition 4.5.** Let \( C \) be a \( G \)-equivariant cosheaf on \( \mathcal{X} \). Let \( x_1, x_2 \ldots \) be representatives of \( G \)-orbits on \( \mathcal{X}_n \). Then the following statements hold:

(1) There is an isomorphism of \( G \)-modules

\[ C_n(\mathcal{X}, C) \cong \bigoplus_k a - \text{Ind}_{G_{x_k}}^G C_{x_k}. \]
(2) Chains $C_n(\mathcal{X}_\bullet, \mathcal{C})$ and homologies $H_n(\mathcal{X}_\bullet, \mathcal{C})$ are smooth $G$-representations.

(3) If $\mathcal{C}$ is $A$-semisimple (with a character $\chi$), then chains $C_n(\mathcal{X}_\bullet, \mathcal{C})$ and homologies $H_n(\mathcal{X}_\bullet, \mathcal{C})$ are $A$-semisimple (with a character $\chi$ respectively).

(4) If $\mathcal{C}$ is discrete and $\mathcal{X}_n$ has finitely many $G$-orbits, then chains $C_n(\mathcal{X}_\bullet, \mathcal{C})$ and homologies $H_n(\mathcal{X}_\bullet, \mathcal{C})$ are in $\mathcal{M}(G)^{\mathbb{C}}$. More precisely, $C_n(\mathcal{X}_\bullet, \mathcal{C})$ and $H_n(\mathcal{X}_\bullet, \mathcal{C})$ are in $\mathcal{M}(G)^{\mathbb{C}}$ where $K = K_1 \cap K_2 \cap \ldots \cap K_k$ and $K_i$ is the kernel of the $G_x$-representation $C_{x_i}$.

(5) If $X_n$ has finitely many $G$-orbits and $C_{x_i}$ is finitely generated $G_{x_i}$-module for each $x_i$, then chains $C_n(\mathcal{X}_\bullet, \mathcal{C})$ and homologies $H_n(\mathcal{X}_\bullet, \mathcal{C})$ are finitely generated $G$-modules.

(6) Suppose that for each $x \in X_n$, the stabiliser $G_x$ is compact modulo $A$ and the field $\mathbb{F}$ is $G_x/A$-ordinary. If $\mathcal{C}$ is $A$-semisimple (with a character $\chi$), then the space of chains $C_n(\mathcal{X}_\bullet, \mathcal{C})$ is a projective object in $\mathcal{M}_{A}(G)$ (correspondingly in $\mathcal{M}_{A,A}(G)$).

(7) If $\mathcal{X}_n$ is $n$-dimensional (i.e., $\mathcal{X}(n) \neq \emptyset$ and $\mathcal{X}(k) = \emptyset$ for $k > n$), then $H_k(\mathcal{X}_\bullet, \mathcal{C}) = 0$ for $k > n$.

(8) If faces of non-degenerate simplices in $\mathcal{X}_\bullet$ are non-degenerate, then the embedding of complexes $(C_\bullet(\mathcal{X}_\bullet, \mathcal{C}), d_\bullet) \hookrightarrow (C_\bullet(\mathcal{X}_\bullet, \mathcal{C}), d_\bullet)$ is a homotopy equivalence (in the category of complexes over $\mathcal{M}(G)$).

Proof. All statements are proved one by one from (1) to (8). Statement (6) requires Corollary 5.2 while the rest of the statements are straightforward.

Let us examine the functors connecting cosheaves and representations. The functors from representations to cosheaves are localisation functors: they produce an equivariant cosheaf, a local object from a representation. The easiest localisation functor is the trivial cosheaf:

$$L : \mathcal{M}(G) \to \text{Csh}_{G}(\mathcal{X}_\bullet), \quad L((\rho, V)) = V.$$ 

In the opposite direction, we have homology functors

$$\mathcal{H} : \text{Csh}_{G}(\mathcal{X}_\bullet) \to \mathcal{M}(G), \quad \mathcal{H}(\mathcal{C}) = H_0(\mathcal{X}_\bullet, \mathcal{C}).$$

Let $\Sigma \subset \text{Mor}(\text{Csh}_{G}(\mathcal{X}_\bullet))$ be the class of those morphisms $f$ such that $\mathcal{H}(f)$ is an isomorphism. We can get a functor from the category of left fractions [10 I.1.1]:

$$\mathcal{H}[\Sigma^{-1}] : \text{Csh}_{G}(\mathcal{X}_\bullet)[\Sigma^{-1}] \to \mathcal{M}(G).$$

The category of fractions always exists and admits a natural fraction functor $\mathcal{Q}_\Sigma : \text{Csh}_{G}(\mathcal{X}_\bullet) \to \text{Csh}_{G}(\mathcal{X}_\bullet)[\Sigma^{-1}]$. However, in general this category is intractable. It needs to satisfy the left Ore conditions (or admit the left calculus of fractions in the terminology of Gabriel and Zisman [10 I.2.2]) to enable working with them:

Lemma 4.6. [10 I.3] Let $\mathcal{A}$ be an abelian category, $\Sigma$ a class of morphisms in it admitting a left calculus of fractions. Then $\mathcal{A}[\Sigma^{-1}]$ is an additive category with finite colimits.

In particular, there are cokernels in $\mathcal{A}[\Sigma^{-1}]$. An instructive exercise is to show that for a morphism $s^{-1}f$ in $\mathcal{A}[\Sigma^{-1}]$ the composition $\text{coker}(fs)$ is its cokernel, yet $\text{ker}(f)$ is not necessarily its kernel. To obtain a kernel one needs the right calculus of fractions. If $\Sigma$ admits both left and right calculi of fractions, then $\mathcal{A}[\Sigma^{-1}]$ is abelian [10 I.3.6].
We are ready for the main theorem of the section, which is a generalisation of Localisation Theorem by Schneider and Stuhler [21, Theorem V.1]. We follow their strategy in our proof. It is important to notice that no restriction on \( F \) appears in the theorem.

**Theorem 4.7.** (Localisation Theorem) Consider a continuous action of the locally compact totally disconnected group \( G \) on a simplicial set \( \mathcal{X}_* \), where the central subgroup \( A \) acts trivially. The following statements hold.

1. The class \( \Sigma \) of morphisms \( f \) in \( \text{Csh}_G(\mathcal{X}_*) \) such that \( \mathcal{H}(f) \) is an isomorphism admits a calculus of left fractions.
2. \( \mathcal{H}[\Sigma^{-1}]: \text{Csh}_G(\mathcal{X}_*)[\Sigma^{-1}] \to \mathcal{M}(G) \) is conservative, i.e., a morphism \( f \) is an isomorphism if and only if \( \mathcal{H}[\Sigma^{-1}](f) \) is an isomorphism.
3. \( \mathcal{H}[\Sigma^{-1}] \) commutes with colimits.
4. \( \mathcal{H}[\Sigma^{-1}] \) is faithful, i.e., injective on morphisms.

If \( |\mathcal{X}| \) is connected, then the following three statements hold:

5. \( \mathcal{H}[\Sigma^{-1}]: \text{Csh}_G(\mathcal{X}_*)[\Sigma^{-1}] \to \mathcal{M}(G) \) is an equivalence of categories.
6. \( Q_\Sigma \circ \mathcal{L} \) is a quasi-inverse of \( \mathcal{H}[\Sigma^{-1}] \).
7. These equivalences restrict to equivalences \( \text{Csh}_{G,A}(\mathcal{X}_*)[\Sigma_A^{-1}] \xrightarrow{\cong} \mathcal{M}_{A}(G) \) and \( \text{Csh}_{G,A,\mathcal{X}}(\mathcal{X}_*)[\Sigma_{A,\mathcal{X}}^{-1}] \xrightarrow{\cong} \mathcal{M}_{A,\mathcal{X}}(G) \) where \( \Sigma_A \) and \( \Sigma_{A,\mathcal{X}} \) are intersections of \( \Sigma \) with the corresponding subcategories.

**Proof.** A short exact sequence of cosheaves gives rise to a long exact sequence in homology. Consequently, the functor \( \mathcal{H} \) is right exact. Hence, it commutes with finite direct limits (cf. [10, Prop. 3.3.3], the statement proved there is that a left exact functor commutes with finite inverse limits. Apply the opposite categories to dualise it). The first three statements follow [10, I.3.4].

Suppose \( \mathcal{H}[\Sigma^{-1}](f) = \mathcal{H}[\Sigma^{-1}](f') \) for two morphisms \( f \) and \( f' \). To prove that \( f = f' \) it suffices to show that \( \text{coker}(f - f') \) is an isomorphism (cokernels exist by Lemma 4.6). By (3), \( \mathcal{H}[\Sigma^{-1}](\text{coker}(f - f')) = \text{coker}(\mathcal{H}[\Sigma^{-1}](f) - \mathcal{H}[\Sigma^{-1}](f')) = \text{coker}(0) \) is an isomorphism. By (2) \( \text{coker}(f - f') \) is an isomorphism. This proves (4).

Since \( |\mathcal{X}| \) is connected, we have an exact sequence

\[
C_1(\mathcal{X}_*, F) \xrightarrow{d_1} C_0(\mathcal{X}_*, F) \xrightarrow{w} F \to 0,
\quad w\left( \sum_x \alpha_x x \right) = \sum_x \alpha_x.
\]

Observe that for a smooth \( G \)-representation \( V \) the tensor product \( C_k(\mathcal{X}_*, F) \otimes V \) is naturally isomorphic as a \( G \)-representation to \( C_k(\mathcal{X}_*, \mathcal{V}) \). Hence, tensoring with \( V \) produces another exact sequence

\[
C_1(\mathcal{X}_*, \mathcal{V}) \xrightarrow{d_1} C_0(\mathcal{X}_*, \mathcal{V}) \to V \to 0
\]

that gives a natural isomorphism \( \mathcal{H}[\Sigma^{-1}] \circ (Q_\Sigma \circ \mathcal{L}) \cong \text{Id}_{\mathcal{M}(G)}; \)

\[
\mathcal{H}[\Sigma^{-1}](Q_\Sigma(\mathcal{L}(V))) \cong \mathcal{H}(\mathcal{L}(V)) = H_0(\mathcal{X}_*, \mathcal{V}) \cong V.
\]

In the opposite direction, we need a natural transformation \( \gamma : \text{Id}_{\text{Csh}_G(\mathcal{X}_*)[\Sigma^{-1}]} \to (Q_\Sigma \circ \mathcal{L}) \circ \mathcal{H}[\Sigma^{-1}] \)
that we define in $\text{Csh}_G(\mathcal{X}_\bullet)$ for each cosheaf $\mathcal{C}$ by

$$\gamma(\mathcal{C})_x := \begin{cases} \mathcal{C}_x \ni \alpha \mapsto 0 \in \mathcal{H}(\mathcal{C}) & \text{if } x \in \mathcal{X}_n, \ n > 0, \\ \mathcal{C}_x \ni \alpha \mapsto [\alpha x] \in \mathcal{H}(\mathcal{C}) & \text{if } x \in \mathcal{X}_0. \end{cases}$$

Observe that $\mathcal{H}(\gamma(\mathcal{C}))$ is an isomorphism. By (2), $\gamma(\mathcal{C})$ is an isomorphism, so $\gamma$ is a natural isomorphism. This proves (5) and (6).

To attack (7), observe a fine difference between $\text{Csh}_{G,A}(\mathcal{X}_\bullet)[\Sigma^{-1}]$ and $\text{Csh}_{G,A}(\mathcal{X}_\bullet)[\Sigma_A^{-1}]$. The former is a full subcategory of $\text{Csh}_{G,A}(\mathcal{X}_\bullet)[\Sigma^{-1}]$, while the latter is the category of fractions of $\text{Csh}_{G,A}(\mathcal{X}_\bullet)$. They are connected by a natural functor $\mathcal{N} : \text{Csh}_{G,A}(\mathcal{X}_\bullet)[\Sigma_A^{-1}] \to \text{Csh}_{G,A}(\mathcal{X}_\bullet)[\Sigma^{-1}]$, identical on objects and morphisms. Clearly, $\mathcal{N}$ is an equivalence. It remains to observe that (Csh$_{G,A}(\mathcal{X}_\bullet)[\Sigma^{-1}]) \subseteq \mathcal{M}_A(G)$ and $\mathcal{Q}_\Sigma(\mathcal{L}(\mathcal{M}_A(G))) \subseteq \text{Csh}_{G,A}(\mathcal{X}_\bullet)[\Sigma^{-1}]$. Both inclusions are straightforward. □

Theorem 4.7 may or may not bring any new information about representations of $G$ to the table. For instance, any $G$ acts on the point. Then this theorem is a tautology, producing the identity functor on $\mathcal{M}(G)$. Another interesting thought experiment is to replace $G$ with a product $G \times H$ where $H$ acts trivially on $\mathcal{X}_\bullet$. All information about the $H$-action on $\mathcal{M}(G \times H)$ is wiped under the carpet in $\text{Csh}_{G \times H}(\mathcal{X}_\bullet)$: $H$ needs to act somehow on all $\mathcal{C}_x$ for all equivariant cosheaves. On the other hand, Theorem 3.4 demonstrates that the localisation over simplicial sets can provide new non-trivial information.

Can we trim down the category of cosheaves by using systems of subgroups? If $G_x$ is a contravariant system of subgroups, we have an exact sequence

$$C_1(\mathcal{X}_\bullet, V^G) \overset{d_1}{\longrightarrow} C_0(\mathcal{X}_\bullet, V^G) \overset{w}{\longrightarrow} V, \quad w\left(\sum_x \alpha_x x\right) = \sum_x \alpha_x.
$$

Using it, we can get a version of Theorem 4.7 for discrete cosheaves. Let $\Sigma^G$, $\Sigma^G_A$ and $\Sigma^G_{A,\chi}$ be the intersections of $\Sigma$ with $\text{Csh}_G(\mathcal{X}_\bullet)$, $\text{Csh}_{G,A}(\mathcal{X}_\bullet)$ and $\text{Csh}_{G,A,\chi}(\mathcal{X}_\bullet)$ correspondingly.

Corollary 4.8. Suppose that $|\mathcal{X}|$ is connected and there are finitely many $G$-orbits on $\mathcal{X}_0$. Suppose further that for any representation $V \in \mathcal{M}(G)^\circ$ there exists an open contravariant system of subgroups $\mathcal{G}$ such that the following variation of sequence (7) is exact:

$$C_1(\mathcal{X}_\bullet, V^G) \overset{d_1}{\longrightarrow} C_0(\mathcal{X}_\bullet, V^G) \overset{w}{\longrightarrow} V \to 0.
$$

Then the functor $\mathcal{H}[\Sigma^{-1}]$ provides equivalences $\text{Csh}_G^\circ(\mathcal{X}_\bullet)[\Sigma^{-1}] \cong \mathcal{M}(G)^\circ$, $\text{Csh}_{G,A}^\circ(\mathcal{X}_\bullet)[\Sigma_A^{-1}] \cong \mathcal{M}_A(G)^\circ$, and $\text{Csh}_{G,A,\chi}^\circ(\mathcal{X}_\bullet)[\Sigma_{A,\chi}^{-1}] \cong \mathcal{M}_{A,\chi}(G)^\circ$.

Proof. Similarly to the proof of Theorem 4.7, the difference between $\text{Csh}_G^\circ(\mathcal{X}_\bullet)[\Sigma^{-1}]$ and $\text{Csh}_{G,A}^\circ(\mathcal{X}_\bullet)[\Sigma_A^{-1}]$ is immaterial. Parts (3) and (4) of Proposition 4.7 tell us that $\mathcal{H}[\Sigma^{-1}]$ is a well-defined functor $\text{Csh}_G^\circ(\mathcal{X}_\bullet)[\Sigma^{-1}] \to \mathcal{M}(G)^\circ$. Ditto for the $A$-semisimple categories.

If $V \in \mathcal{M}(G)^\circ$, we pick the aforementioned (in the statement) system of subgroups $\mathcal{G}$. Then the trivial cosheaf $\mathcal{Q}_\Sigma(\mathcal{L}(V)) = \overset{\sim}{V}$ is isomorphic to the cosheaf $\overset{\sim}{V}$ in $\text{Csh}_G(\mathcal{X}_\bullet)[\Sigma^{-1}]$. The latter cosheaf is discrete because $G_x$ acts on $V^G_x$ via the discrete quotient $G_x/G_x$. It is easy to see $A$-semisimplicity through as well. □
If $V$ is admissible and $\mathcal{G}$ is compact open, then the cosheaf $V^G_\sim$ is finite dimensional, i.e., each vector space $V^G_x$ is finite dimensional. Thus, it has a chance of giving us a resolution of $V$ by finitely generated projective modules. We will address this problem in the next section.

Finally, let us comment why we think cosheaves are better than sheaves for our studies. If $\mathcal{F}$ is an equivariant sheaf, the cohomology $\text{H}^n(\mathcal{X}, \mathcal{F})$ is not necessarily a smooth representation of $G$. Taking its smooth part, one gets a smooth cohomology complex $\text{C}^m(\mathcal{X}, \mathcal{F})$, whose relation to the topology of $\mathcal{X}$ is more remote than of the original complex $\text{C}^*(\mathcal{X}, \mathcal{F})$. In particular, one could expect a subtle, yet fruitful interplay between $\text{C}^*(\mathcal{X}, V)$, $\text{C}^m(\mathcal{X}, V)$ and $V$, but it remains to be seen whether this mesh is capable of producing something useful, for instance, injective resolutions of $V$.

5. Schneider-Stuhler Resolution

We call a finitely generated projective resolution of the form $\text{C}^*(\mathcal{X}, V^G)$ a Schneider-Stuhler resolution, acknowledging their construction for $p$-adic algebraic groups [21]. Where do suitable (for such resolutions) systems of subgroups come from?

Denote by $f_i^a$ the function $f_i^a : [0] \to [n]$, $f_i^a(0) = i$. Suppose we are given a compact open subgroup $\mathcal{G}_x$ for each vertex $x \in \mathcal{X}_0$ such that

1. $\mathcal{G}_{gx} = g\mathcal{G}_x g^{-1}$ for all $g \in G$, $x \in \mathcal{X}_0$ and
2. $\mathcal{G}_x \mathcal{G}_y = \mathcal{G}_y \mathcal{G}_x$ if $x$ and $y$ are adjacent, i.e., $x = \mathcal{X}(f_0^1)(w)$, $y = \mathcal{X}(f_1^1)(w)$ for some $w \in \mathcal{X}_1$.

Condition (2) allows us to extend this collection of subgroups to a compact open contravariant system of subgroups by taking products over vertices:

$$\mathcal{G}_x := \mathcal{G}_{\mathcal{X}(f_0^1)x} \mathcal{G}_{\mathcal{X}(f_1^1)x} \cdots \mathcal{G}_{\mathcal{X}(f_n^1)x} \text{ for all } x \in \mathcal{X}_n.$$ 

We call a compact open contravariant system obtained by this construction from some initial choice of subgroups an exquisite system.

If the field $\mathbb{F}$ is $\mathcal{G}_x$-ordinary for each $x \in \mathcal{X}_0$, then it is $\mathcal{G}_x$-ordinary for each $x \in \mathcal{X}$, as soon as we deal with an exquisite system. As observed by Meyer and Solleveld [19], this gives us idempotents $\Lambda_x := \Lambda_{G_x} \in \mathcal{H} = \mathcal{H}(G, \mathbb{F}, \mu)$ for a suitable choice of $\mu$ (notation of Section 4). Not only are these idempotents convenient for calculations but also they control the invariants: $V^G_x = \Lambda_x \ast V$.

Lemma 5.1. (cf. [19]) The collection $\Lambda_x, x \in \mathcal{X}$, of idempotents arisen from an exquisite system of subgroups satisfies the following identities:

1. $\Lambda_x \ast \Lambda_y = \Lambda_y \ast \Lambda_x$ if $x, y \in \mathcal{X}_0$ are adjacent.
2. $\Lambda_x = \Lambda_{\mathcal{X}(f_0^1)x} \ast \Lambda_{\mathcal{X}(f_1^1)x} \ast \cdots \ast \Lambda_{\mathcal{X}(f_n^1)x}$ for all $x \in \mathcal{X}_n$.
3. $\Lambda_{\mathcal{G}x} = \mathcal{G} \Lambda_x \mathcal{G}^{-1}$ for all $g \in G, x \in \mathcal{X}$.

Proof. By definition

$$\Lambda_x \ast \Lambda_y(g) = \int_G \Lambda_x(h) \Lambda_y(h^{-1}g) \mu(dh).$$
The integrand vanishes unless \( h \in G_x \), \( h^{-1} g \in G_y \). Thus \( \Lambda_x \ast \Lambda_y \) is supported on \( G_x G_y \). Moreover, \( h^{-1} g \in G_y \) translates into \( h \in g G_y \) so that (9) becomes

\[
\int_{G_x \cap g G_y} \Lambda_x(h) \Lambda_y(h^{-1} g) \mu(\mathcal{d}h) = \frac{\mu(G_x \cap g G_y)}{\mu(G_x) \mu(G_y)}.
\]

Decomposing \( g = h(h^{-1} g) \) for some \( h \in G_x \), \( h^{-1} g \in G_y \), (9) becomes

\[
\frac{\mu(G_x \cap h G_y)}{\mu(G_x) \mu(G_y)} = \frac{\mu(h^{-1}(G_x \cap h G_y))}{\mu(G_x) \mu(G_y)} = \frac{1}{\mu(G_x \cap G_y)} = \Lambda_{\mathcal{G},G_y}(g).
\]

Since \( G_x G_y = G_y G_x \), we have proved not only (1) but a stronger equation

\[
\Lambda_x \ast \Lambda_y = \Lambda_{\mathcal{G},G_y} = \Lambda_y \ast \Lambda_x.
\]

Statement (2) follows from Equation (10) by an easy induction and the last statement is obvious. 

Let \( |\mathcal{X}| \) be the geometric realisation of the simplicial set \( \mathcal{X} = (\mathcal{X}_n) \). For a non-degenerate \( x \in \mathcal{X} \) we denote the corresponding simplex in \( |\mathcal{X}| \) by \( \Delta_n \times x \) and its points by \( x = (\alpha, x), y = (\alpha, y) \), etc. A particular point of interest is the centre

\[
\hat{x} = ((\frac{1}{n}, \ldots, \frac{1}{n}), x) \text{ (see Section 4)}.
\]

We make an additional assumption that \( |\mathcal{X}| \) admits a CAT(0)-metric. Then \( |\mathcal{X}| \) is a unique geodesic space [3], in particular, any two points \( x, y \in |\mathcal{X}| \) can be connected by a unique geodesic, which we denote by \( [x, y] \). A subset \( Y \subseteq |\mathcal{X}| \) is called convex if \( [x, y] \subseteq Y \) for all \( x, y \in Y \). The convex hull \( \text{Hull}(Y) \) of \( Y \) is the intersection of all convex subsets of \( |\mathcal{X}| \) containing \( Y \). Notice that \( [x, y] = \text{Hull}([x, y]) \).

Let \( \mathcal{G} \) be a system of subgroups of \( G \). We would like to have some control over the subgroups \( G_x \), along geodesics. Bearing this in mind, we propose the following definition:

**Definition 5.2.** We say that a contravariant system of subgroups \( \mathcal{G} \) is **geodesic** if for all \( x, y \in |\mathcal{X}| \)

\[
G_z \subseteq G_x G_y
\]

where \( z \in \mathcal{X}_0 \) is a vertex of the first simplex \( u \in \mathcal{X}_\alpha \) along the geodesic \( [x, y] \), i.e., \( z = \mathcal{X}(f_i^n)u \) for some \( i \) and \( (\Delta_n \times u) \cap [x, y] = [x, v] \) for some \( v \in [x, y] \).

The significance of this definition transpires in the following lemma:

**Lemma 5.3.** Suppose that \( |\mathcal{X}| \) admits a CAT(0)-metric, \( G_x \) is a geodesic, \( \mathcal{F} \) is the system and the field \( \mathcal{F} \) is \( G_x \)-ordinary for each \( x \in \mathcal{X}_0 \). Then \( \Lambda_x \ast \Lambda_z \ast \Lambda_y = \Lambda_x \ast \Lambda_y \) and \( \Lambda_x \ast \Lambda_z = \Lambda_z \ast \Lambda_x \), as soon as \( x, y, z \in \mathcal{X} \) satisfy the conditions spelled out in Definition 5.2.

**Proof.** If \( z = \mathcal{X}(f_i^n)u \) as in Definition 5.2, then \( \Lambda_x \) is a product of various \( \Lambda_{\mathcal{X}(f^n)u} \), hence, commutes with \( \Lambda_z \). The first equality easily follows from the geodesic condition \( G_z \subseteq G_x G_y \).

Now consider a character \( \chi : A \rightarrow \widehat{\mathbb{R}^\mathbb{X}} \). Given a subgroup \( H \leq G \), set \( H_\chi := H/H \cap \ker(\chi) \). It is a subgroup of \( G_\chi \). Observe that \( H_\chi \) is compact if and only if \( H \) is compact modulo \( A \). We are ready for the main conjecture of this section:
Conjecture 5.4. Let $G$ be a locally compact totally disconnected group, $A$ its closed central subgroup. Suppose $G$ acts smoothly on a simplicial set $\mathcal{X}$ of dimension $n$, with $A$ acting trivially. Further suppose that a face of a non-degenerate simplex in $\mathcal{X}$ is non-degenerate and $|\mathcal{X}|$ admits a CAT(0)-metric such that the faces are geodesic, i.e., $\text{Hull}(\Delta_i \times x) = \Delta_i \times x$ for each $x \in \mathcal{X}(\ast)$. If $V \in M_{A, \chi}(G)$, the following four statements should conjecturally hold:

1. If $G$ is a geodesic exquisite system of subgroups of $G_\chi$ such that $F$ is $G_\chi$-ordinary for all $x \in X_0$, then the complex
   \[ 0 \to C_n(A, \mathcal{V}_G) \xrightarrow{d_n} C_{n-1}(A, \mathcal{V}_G) \xrightarrow{d_{n-1}} \cdots \xrightarrow{d_1} C_0(A, \mathcal{V}_G) \xrightarrow{w} V \]
   is an exact sequence.

2. Each $C_k(A, \mathcal{V}_G)$ is a projective module in $M_{A, \chi}(G)$.

3. If $(\pi, V)$ is generated by invariants $V^{G_\chi}$ for some $x \in X_0$, then the complex is a projective resolution of $V$ in $M_{A, \chi}(G)$.

4. If $(\pi, V)$ is admissible and $\mathcal{X}^{(k)}$ has finitely many $G$-orbits, then $C_k(A, \mathcal{V}_G)$ is a finitely generated $G$-module.

In fact, statements (2)–(4) are established in Proposition 4.3. Only statement (1) is truly a conjecture. We can prove its partial case:

Theorem 5.5. If the dimension of $|\mathcal{X}|$ is one, then Conjecture 5.3 holds.

Proof. (1), exactness at $C_0(A, \mathcal{V}_G)$: The inclusion $\text{im}(d_1) \subseteq \ker(w)$ is clear. Let us show that $\ker(w) \subseteq \text{im}(d_1)$. Pick a 0-cycle $\alpha = \sum_{i=1}^n \alpha_i x_i \in C_0(A, \mathcal{V}_G)$ where all $\alpha_i \neq 0$. Consider the hull of its support $Y := \text{Hull}(\{x_1, \ldots, x_n\})$. Under our conditions $|\mathcal{X}|$ is a tree, so $Y$ is a finite tree. Hence, $Y$ has an endpoint. Without loss of generality, $\hat{x}_1$ is an endpoint. Let $x_1' \in X_0$ be the unique vertex adjacent to $x_1$ such that $\hat{x}_1 \in Y$. Let $e_1 \in X_1$ be the edge connecting $x_1$ and $x_1'$. Since $w(\alpha) = \sum_{i=1}^n \alpha_i = 0$ and $A_{x_1}(\alpha_i) = \alpha_i$, we conclude that

\[ \sum_{i=1}^n \Lambda_{x_1}(\alpha_i) = 0. \]

Applying $\Lambda_{x_1} \cdot (1 - \Lambda_{x_i'})$ to Equation (11), we can rewrite each summand separately, using Lemmas 5.1 and 5.3

- $\Lambda_{x_1} \cdot (1 - \Lambda_{x_i'}) \cdot \Lambda_{x_1}(\alpha_1) = (1 - \Lambda_{x_i'})(\alpha_1),$
- $\Lambda_{x_i} \cdot (1 - \Lambda_{x_i'}) \cdot \Lambda_{x_1}(\alpha_i) = 0$ for $i \geq 2.$

Thus, $\alpha_1 \in \ker(1 - \Lambda_{x_i'})$ and $\alpha_1 \in \text{im}(\Lambda_{x_1'})$. Then \[ \alpha' := \alpha_1 x_1' + \sum_{i=2}^n \alpha_i x_i = d_1(\pm \alpha_1 e_1) + \alpha \in C_0(A, \mathcal{V}_G) \]
and the hull of the support of $\alpha'$ is a proper subset of $Y$. An easy induction on the size of the hull of the support completes the proof.

(1), exactness at $C_1(A, \mathcal{V}_G)$: Pick a 1-cycle $\alpha = \sum_{i=1}^n \alpha_i x_i \in C_1(A, \mathcal{V}_G)$ where all $\alpha_i \neq 0$. Consider the hull of its support $Y := \text{Hull}(\{\hat{x}_1, \ldots, \hat{x}_n\})$. Again $Y$ is a finite tree, so $Y$ has an endpoint, e.g., $\hat{x}_1$. Let $z \in X_0$ be the unique vertex of the
edge $x_1$ such that $\hat{z} \not\in Y$. Clearly, $d_1(\alpha) = \pm \alpha_1 z + \ldots$ has a non-zero coefficient in front of $z$. This proves that $\alpha = 0$ and $d_1$ is injective. \hfill \Box

6. Davis Building for a Group with Generalised BN-pair

Let $G$ be an abstract group. Following Iwahori [15], a generalised BN-pair on a group $G$ is a triple $(B, N, S)$ satisfying the following conditions:

(i) $B$ and $N$ are subgroups of $G$. $H = B \cap N$ is a normal subgroup of $N$.
(ii) $N/H = \Omega \ltimes W$ where $\Omega$ is a subgroup and $W$ is a normal subgroup.
(iii) $W$ is generated by the set $S$. The elements of $S$ have the following properties:

(iii.1) For any $t$ in $\Omega \ltimes W$ and any $s \in S$ we have $tBst \subset BtB \cup BtB$ where $t$ and $s$ are elements of $G$ lifting $t$ and $s$.
(iii.2) $s^2 = 1$ and $sBst^{-1} \neq B$ for all $s \in S$.
(iv) $\text{aSa}^{-1} = S$ for all $a \in \Omega$.
(v) $\hat{B}a^{-1}B = B$ for all $a \in \Omega$ and $\hat{B}a \neq B$ for any $a \in \Omega \setminus \{1\}$.
(vi) $G$ is generated by $B$ and $N$.

As usual $W$ is called the Weyl group of $G$. Note that $W$ is a Coxeter group and thus $(W, S)$ is a Coxeter system. We call $\Omega \ltimes W$ the generalised Weyl group. It is rather ironic that a BN-pair is a triple but it is a moot point whether $B$ and $N$ uniquely determine $S$ for generalised BN-pairs. Thus, we include $S$ into the definition for safety.

Given a group $G$ with a generalised BN-pair, we can find a smaller group $G_0$ inside $G$ which has a BN-pair. More precisely, define $G_0 := BWB$. Then the following statements hold [15]:

Lemma 6.1. (1) $G_0$ is a normal subgroup of $G$ and $G/G_0 \cong \Omega$.
(2) $(B, N_0)$ is a BN-pair for $G_0$, where $N_0 = N \cap G_0$. The Weyl groups of $G_0$ and $G$ are the same.
(3) The automorphism of $G_0$ defined by conjugation by an element $g \in G$ preserves the BN-pair up to conjugacy in $G_0$, i.e., there exists $g_0 \in G_0$ such that $gB_0^{-1}g_0 = g_0B_0^{-1}g$ and $gN_0g^{-1} = g_0N_0g_0^{-1}$.

A group with a BN-pair is an obvious example of a group with generalised BN-pair. For a subtler example, consider a group $G$ with a BN-pair $(B, N)$ and another group $\Omega$. The group $\Omega \times G$ admits a BN-pair $(\Omega \times B, \Omega \times N)$ and a generalised BN-pair $(B, \Omega \times N)$. The Weyl groups are the same in both cases but the generalised Weyl group is bigger: $\Omega/H = \Omega \times W$ for the latter pair.

For an example pertinent for our investigation, consider $G = \text{GL}_n(K)$ over a non-Archimedean local field $K$, its Iwahori subgroup $\text{I}$ and its subgroup of monomial matrices $N$. The pair $(\text{I}, N)$ is not a generalised BN-pair: it satisfies all axioms except (ii). Indeed, $\text{I} \cap N = \text{Diag}_n(\text{O}_K^n, \ldots, \text{O}_K^n) \cong (\text{O}_K^n)^n$ consists of diagonal matrices with coefficients in the ring of integers $\text{O}_K \triangleleft K$. Denote $T = \text{Diag}_n(K^*, \ldots, K^*) \cong (K^*)^n$. Then $N/(\text{I} \cap N) \cong N/T \times T/H \cong S_n \times \mathbb{Z}^n$. It contains the Weyl group $W = S_n \times \mathbb{Z}_0^n$ of type $\hat{A}_{n-1}$ as a normal subgroup (where $\mathbb{Z}_0^n = \{(x_i) \mid \sum_i x_i = 0\}$) but there exists no complementary subgroup $\Omega$.

A generalised BN-pair on $G = \text{GL}_n(K)$ is $(B, N)$ where $N$ is as above and $B = Z(G)$. Indeed, $H = Z(G)\text{Diag}_n(\text{O}_K^n, \ldots, \text{O}_K^n) \cong K^*(\text{O}_K^n)^n$ and $N/H \cong S_n \times \mathbb{Z}_0^n$ where $\mathbb{Z}_0^n = \mathbb{Z}^n / ((1, 1, \ldots, 1))$. The generalised Weyl group contains the Weyl group $W = S_n \times \mathbb{Z}_0^n$ of type $\hat{A}_{n-1}$ as a normal subgroup of index $n$. A complementary
group can be chosen as \( \Omega = \langle (1,0,\ldots,0) \cdot \gamma \rangle \cong C_n \) where \( \gamma = (1,2,\ldots,n) \in S_n \). Finally, \( G_0 = BWB \) consists of those matrices whose determinant is in \( \langle \pi^n \rangle O_K^\times \) where \( \pi \in O_K \) is a uniformizer.

Back to any group \( G \) with a generalised BN-pair, Lemma 6.1 guarantees not only the existence of a building of \( G_0 \) of type \( (W,S) \), say \( BT \), but also that \( BT \) admits a well-defined simplicial \( G \)-action. The fundamental apartment of \( BT \) is the Coxeter complex associated to the Coxeter system \( (W,S) \). Hence, there exists a labelling which identifies each vertex of the fundamental chamber \( C \) with an element of \( S \).

We know that both \( G \) and \( G_0 \) act on \( BT \). Let \( G_1 \) be the subgroup of \( G \) that consists of all label-preserving elements. The following lemma summarises its properties:

**Lemma 6.2.** The following statements hold in the notations above.

1. \( G_1 \) is a normal subgroup of \( G \) containing \( G_0 \).
2. If \( K \) is the kernel of the \( G \)-action on \( BT \), then \( G_1 = KG_0 \).
3. \((KB,N_1)\) is a BN-pair for \( G_1 \), where \( N_1 = N \cap G_1 \).
4. The buildings and the Weyl groups of \( G_0 \) and \( G_1 \) are the same.
5. \((KB,N)\) is a generalised BN-pair for \( G \) with the same Weyl group \( (W,S) \).
6. If \( S \) is finite and the generalised Weyl group for the pair \((KB,N)\) is \( \Omega_1 \lt W \), then the constituent group \( \Omega_1 \) is finite.

**Proof.** (1) is obvious.

To prove (2) pick \( g_0 \in G_0 \) for any \( g \in G_1 \) as in Lemma 6.1. These elements \( g \) and \( g_0 \) act in the same way on the set of chambers in \( BT \). Since both preserve the labelling, they act on \( BT \) in the same way and \( g \in K g_0 \subseteq KG_0 \).

Once we know (2), (3) and (4) follow from the label-preserving action of \( G_1 \) on \( BT \), while (5) is a straightforward check of axioms.

To prove (6), consider \( g,h \in G \) changing the labelling in the same way. Then the element \( gh^{-1} \) does not change the labelling and hence \( gh^{-1} \in G_1 \). In other words, we have an injective map:

\[ \Omega_1 \cong G/G_1 \longrightarrow S_n, \]

where \( n = \text{rank}(BT) = |S| \). \( \square \)

We will use the following adjectives for subgroups of \( (W,S) \) and \( G \):

- A subgroup \( W_J \) of \( W \) is *special* if it is generated by some \( J \subset S \). \( J \) is called a special subset.
- If a special subgroup \( W_J \) is finite, it is called spherical. Ditto for the set \( J \).
- A subgroup \( P_J \) of \( G_0 \) is called special if it is of the form \( BW_J B \). A coset of a special subgroup of \( G_0 \) is called a special coset.
- A subgroup of \( G_0 \) is called parabolic of type \( J \) if it is conjugate to a subgroup of the form \( BW_J B \). It is called parabolic of finite type if \( W_J \) is spherical.

Denote by \( \text{Sph}(S) \) the set of all spherical subsets of \( S \) and consider the following set:

\[ \mathcal{P} := \bigsqcup_{J \in \text{Sph}(S)} G_0/P_J. \]

This is a partially ordered set with respect to inclusion. Observe that \( g_0 P_{J_0} \leq g_1 P_{J_1} \) if \( J_0 \leq J_1 \) (hence \( P_{J_0} \leq P_{J_1} \), and \( g_0^{-1} g_1 \in P_{J_1} \). Denote by \( D_n \) the set of all chains of \( \mathcal{P} \) of length \( n + 1 \), \( D(n) \subseteq D_n \) the subset of proper chains:

\[ D_n = \{ g_0 P_{J_0} \leq g_1 P_{J_1} \leq \ldots \leq g_n P_{J_n} \}, \quad D(n) = \{ g_0 P_{J_0} \subset g_1 P_{J_1} \subset \ldots \subset g_n P_{J_n} \}. \]
Then $\mathcal{D}_x = (D_n)$ is a simplicial set, whose geometric realisation $|\mathcal{D}|$ is the geometric realisation of the poset $\mathcal{P}$. We call $\mathcal{D}_x$ the Davis building of $G$. The action of $G$ on the Bruhat-Tits building $BT$ induces a simplicial action of $G$ on the Davis building $\mathcal{D}_x$.

**Lemma 6.3.** Let $x = [g_0 P_{J_0} \subseteq \ldots \subseteq g_n P_{J_n}] \in D_n$. The stabiliser $G_x$ is equal to $g_0 B \Omega_n W_{J_0} B g_0^{-1}$ where $\Omega_n = \bigcap_{i=0}^{n} \Omega_{J_i}$ and $\Omega_J$ is the stabiliser of $J$.

**Proof.** By the definition of the partial order, for every $i \leq n$, there exists an element $p_i \in P_{J_i}$ with $g_i^{-1} p_{i} = p_i$. Hence

$$(G_0)_{x_i} = g_i^{-1} p_{i} g_0^{-1} = g_0 p_1 \ldots p_i g_0^{-1}.$$

Now we move on to $G_x$. For every subgroup $P$ of $G$ containing $B$, there exists a unique subset $J \subseteq S$ and a unique subgroup $\Omega'$ of $\Omega$, such that $P = B \Omega' W_{J_0} B$. The subgroup $g_0^{-1} G_x g_0$ contains $B$, hence, it is one of these subgroups. Moreover, as we know its intersection with $G_0$, we can conclude that

$$g_0^{-1} G_x g_0 = G_{g_0^{-1} x} B \Omega' W_{J_0} B = \bigcup_{u \in \Omega'} B u W_{J_0} B$$

for some subgroup $\Omega' \subseteq \Omega$. Clearly, $u \in \Omega'$ if and only if its lifting $\mathfrak{u}$ stabilises all cosets in $g_0^{-1} \cdot x$, i.e., all $P_{J_i}$. Thus, $\Omega' = \bigcap_{i=0}^{n} \Omega_{J_i}$. \hfill $\square$

We say that a topological group $G$ is a topological group of Kac-Moody type if a generalised BN-pair $(B, N, S)$ is selected such that the following properties hold:

1. $G$ is a locally compact totally disconnected topological group.
2. The set $S$ is finite.
3. The subgroup $B$ is open in $G$.
4. The subgroup $N$ contains the kernel $K$ of the $G$-action on the Bruhat-Tits building.
5. If $J \subseteq S$ is a spherical subset, then $P_J / K$ is compact.

Now we are ready for the main result of this section.

**Theorem 6.4.** A topological group $G$ of Kac-Moody type acts continuously on its Davis building $\mathcal{D}_x$. Moreover, the stabiliser of each $x \in D_n$ is compact modulo the action kernel $K$.

**Proof.** The continuity of action is equivalent to all stabilisers $G_x$ being open. This follows from Lemma 6.3 and $B$ being open.

Since $B$ contains the kernel $K$, $G_1 = G_0$ by Lemma 6.2. Moreover, the subgroup $\Omega$ is finite. As $\mathcal{D}_x$ incorporates only spherical parabolic subgroups of $G_0$, each stabiliser $G_x$ is union of finitely many double cosets $B w B$. Since $K$ is normal, $(B w B) / K$ is the quotient topological space of $B / K \times B / K$. Thus, each double coset $B w B$ is compact modulo $K$ and so is $G_x$. \hfill $\square$

The fundamental theorem of Davis is that if $S$ is finite, then $|\mathcal{D}|$ is a CAT(0) geodesic space with a piecewise Euclidean structure [7]. In particular, it is imperative for us that $|\mathcal{D}|$ is contractible. All conditions of Theorem 5.4 and Theorem 5.7 are satisfied. Let us formulate them as a corollary. Observe that the kernel $K$ contains
any central subgroup, so the condition $A \subseteq K$ holds automatically. Observe also that $B/A$ is compact if and only if $K/A$ is compact.

**Corollary 6.5.** Let $G$ be a topological group of Kac-Moody type, $A$ its central closed subgroup such that $B/A$ is compact. The localisation functor for the category of $A$-semisimple $G$-representations over a field $F$

$$\mathcal{M}_A(G) \xrightarrow{\sim} \text{Csh}_{G,A}(D_\bullet)[\Sigma_A^{-1}]$$

is an equivalence of categories. If the field $F$ is $G_x/A$-ordinary for any $x \in D_\bullet$, then

$$\text{proj.dim}(\mathcal{M}_A(G)) \leq \sup_{J \in \text{ph}(S)} |J|$$

where $|J|$ denotes the cardinality of $J$.

We finish this section with another observation about the class of groups we have introduced.

**Theorem 6.6.** A topological group of Kac-Moody type $G$ with compact $B$ is unimodular.

**Proof.** We can use the compact open subgroup $B$ in Proposition 1.2 to compute the modular function. In particular, $\Delta(x) = 1$ for all $x \in B$. Part (v) of the definition of a generalised BN-pair ensures that $\Delta(\hat{a}) = 1$ for all $a \in \Omega$. If $s \in S$, then $\hat{s}^{-1}Bs = \hat{s}B\hat{s}^{-1}$, so again $\Delta(s) = 1$.

The theorem follows because $B, \hat{S}$ and $\hat{\Omega}$ generate $G$. \qed

### 7. Topological Kac-Moody Groups

There are several versions of complete Kac-Moody groups in the literature. The groups described in Kumar’s book [17] are ind-algebraic. They are not locally compact, so of little relevance to our investigation. There are several locally compact Kac-Moody groups including Caprace–Rémy–Ronan groups, Carbone–Garland–Rousseau groups and Kumar–Mathieu–Rousseau groups. A good review of various relevant complete Kac-Moody groups can be found in Marquis’ thesis [18]. An upcoming paper by Capdeboscq and Rumynin [5] contains a general approach to these groups including a construction of a new class of locally pro-$p$-completed groups.

Let $A = (\alpha_{i,j})_{n \times n}$ be a generalised Cartan matrix, $(W, S)$ its Weyl group, $\Delta = (X, Y, \Pi, \Pi^\vee)$ a root datum of type $A$. Following Carter and Chen [6] we can define a Kac-Moody group $G_{\Delta}(K)$ over a field $K$. The topological Kac-Moody is a certain completion $\widehat{G_{\Delta}(K)}$. We refer the reader to the upcoming paper [5] (also cf. [18]) for further details. If the field $K$ is finite, the group $\widehat{G_{\Delta}(K)}$ can be locally compact. It acts on a building of type $(W, S)$. The kernel of this action $K$ is central for some completions; for some other completions very little is known about $K$. By choosing an appropriate subgroup $K_0 \leq K$, we can derive examples of topological groups of Kac-Moody type in the form $G := \widehat{G_{\Delta}(K)}/K_0$. The following proposition summarises what we know about their representations from Corollary 6.5.

**Proposition 7.1.** Let $G = \widehat{G_{\Delta}(K)}/K_0$ be a topological group of Kac-Moody type derived as described in this section, $A$ its central closed subgroup such that $B/A$ is compact. The localisation functor for the category of $A$-semisimple $G$-representations
over a field $\mathbb{F}$

$$\mathcal{M}_A(G) \cong \text{Csh}_{G,A}(D_\bullet)[\Sigma_A^{-1}]$$

is an equivalence of categories. If the field $\mathbb{F}$ is $P_{1/A}$-ordinary for any spherical $J \subseteq S$, then

$$\text{proj. dim}(\mathcal{M}_A(G)) \leq \sup_{J \in \mathcal{Spk}(S)} |J| = f(A),$$

where $f(A)$ is the maximal size of the diagonal minor of $A$ of finite type.

Let us call a generalised Cartan matrix $A$ generic if $f(A) = 1$. Thus, for a generic $A$, we obtain hereditary abelian categories. It would be interesting to investigate them further.

Another direction for further research is Schneider-Stuhler resolutions in $\mathcal{M}_A(G)$ for topological Kac-Moody groups. We are going to address them in consequent papers.

8. Homological Duality

We start with a locally compact totally disconnected group $G$ and its closed central subgroup $A$. We make no restriction on $\mathbb{F}$ for now.

We consider one of the derived categories $D^\bullet(\mathcal{M}(G))$ where $\bullet \in \{\text{"empty"}, - , +, b\}$. We have been working with chain complexes previously, but we feel obliged to switch to cochain complexes at this point to follow standard conventions. Let us consider a full subcategory $D^\bullet(\mathcal{M}(G))_{A,\chi}$ for each character $\chi$ of $A$. It consists of cochain complexes $M^\bullet = (M^n, d^n)$ such that for all $a \in A$ we have an equality $a - \chi(a) = 0$ in $\text{Hom}(M^\bullet, M^\bullet)$. This enables us to define a full subcategory $D^\bullet(\mathcal{M}(G))_A := \bigoplus_{\chi} D^\bullet(\mathcal{M}(G))_{A,\chi}$ consisting of $A$-semisimple complexes. There are two further related categories: a full subcategory $D^\bullet_A(\mathcal{M}(G))$ of complexes with $A$-semisimple cohomology and $D^\bullet(\mathcal{M}_A(G))$. The natural functors $D^\bullet(\mathcal{M}_A(G)) \to D^\bullet(\mathcal{M}(G))_A$ and $D^\bullet(\mathcal{M}(G))_A \to D^\bullet_A(\mathcal{M}(G))$ are not equivalences, in general. It is a moot point when they are (cf. [12, Exercises in III.2]).

Let $B^\bullet$ be a complex of $G$-$G$-bimodules, smooth as both left and right $G$-modules such that the left and the right actions of $A$ on $B^\bullet$ coincide. We denote these actions on $B^n$ by $\ast_b$ and $b \ast$. The bimodule $B$ defines a dual module" for each $M^\bullet \in D(\mathcal{M}(G))$ by

$$\nabla(M^\bullet) = \nabla_B^\bullet(M^\bullet) := \text{Hom}(M^\bullet, B^\bullet), \quad [g \cdot \varphi](m) := (\varphi(m))^{\ast_b^{-1}}.$$ 

Observe that the functor $\nabla$ preserves $D(\mathcal{M}(G))_A$ because the image of $\varphi$ necessarily takes values in the $A$-socle of $B^\bullet$. In fact, $\nabla$ takes $D(\mathcal{M}(G))_{A,\chi}$ to $D(\mathcal{M}(G))_{A,\chi^{-1}}$.

The preservation of other categories depends on $B^\bullet$. We say that $B^\bullet$ is dualising if $\nabla$ restricts to a self-equivalence $D^b(\mathcal{M}^{f,g}(G))_A \to D^b(\mathcal{M}^{f,g}(G))_A$ of the derived categories of finitely generated modules and $\nabla^2$ is naturally isomorphic to $\text{Id}_{D^b(\mathcal{M}^{f,g}(G))_A}$.

It would be extremely interesting to develop a theory of dualising complexes in our generality in the spirit of Hartshorne [13] and, in particular, characterise the dualising complexes as done for rings by Yekutieli [23, Def. 4.1].

**Proposition 8.1.** (cf. [11, Th. 31]) Suppose that the field $\mathbb{F}$ is $K$-ordinary for a compact open subgroup $K$ of $G$. Then the Hecke algebra $\mathcal{H} = \mathcal{H}(G, \mathbb{F}, \mu_K)$ is a dualising bimodule.
Proof. Thanks to Proposition 2.3 we are dealing with modules over the idempotent algebra \( \mathcal{H} \). An object \( M^* \in D^b(\mathcal{M}^{f,g}(G))_A \) admits a projective resolution \( P^* = (P_n, d^n) \simeq M^* \) in \( K^-(\mathcal{M}(G)) \), i.e., \( P_n = 0 \) for \( n \gg 0 \). Each \( P_n \) can be chosen to be a finite direct sum of \( He \) for various idempotents \( e \).

We can compute \( \nabla(M^*) \) on this resolution. The natural action of \( G \) on \( \nabla(M^*) \) is the right actions \([\varphi \mapsto g](m) := (\varphi(m))^g \) that we turn into the left action using the inverses. Let us not do it so that we can treat \( \nabla(P^*) \) as a complex of right \( \mathcal{H} \)-modules. In particular, we can use the natural isomorphism

\[
\nabla(He) = \text{Hom}_\mathcal{H}(He, \mathcal{H}) \cong e\mathcal{H}, \quad F \longmapsto F(e) = eF(e)
\]

to construct the natural isomorphism of functors

\[
\nabla^2 \xrightarrow{\gamma} \text{Id}_{D^b(\mathcal{M}^{f,g}(G))}_A, \quad \nabla^2(P^n) = \nabla^2(\oplus_e e\mathcal{H}) \xrightarrow{\cong} \nabla(\oplus_e e\mathcal{H}) \xrightarrow{\cong} \oplus_e e\mathcal{H} = P^n.
\]

To show that it is well-defined we need to compute what happens to differentials \( d^n \). Each differential is a matrix \((d^n_{e,f})\) where \( d^n_{e,f} \in \text{Hom}_\mathcal{H}(He, e\mathcal{H}) \). Using natural isomorphisms

\[
\text{Hom}_\mathcal{H}(He, e\mathcal{H}) \cong e\mathcal{H}, \quad F \longmapsto F(e) \quad \text{and} \quad \text{Hom}_\mathcal{H}(e\mathcal{H}, e\mathcal{H}) \cong e\mathcal{H}, \quad F \longmapsto F(f),
\]

we can write each \( d^n_{e,f} \) as \( e\Theta_{e,f} \) for some \( \Theta_{e,f} \in \mathcal{H} \) that helps us to perform the key calculation:

\[
\nabla^2(d^n_{e,f}) = \nabla^2((e\Theta_{e,f})) = \nabla((e\Theta_{e,f})) = (e\Theta_{e,f}) = (d^n_{e,f}).
\]

Naturality of the transformation \( \gamma \) is apparent after this calculation. Finally, \( \nabla \) is an equivalence because its quasi-inverse is itself.

We would like to state the following conjecture. At present, we cannot prove it due to our lack of detailed knowledge of representations of \( G \).

Conjecture 8.2. Suppose we are under the assumptions of Proposition 8.1 and \( M \in \mathcal{M}_A(G) \) is a simple module. Then \( \nabla_\mathcal{H}(M) \) is a complex concentrated in one degree.

If Conjecture 8.2 holds, we can write \( \nabla_\mathcal{H}(M) \cong M^\vee [d(M)] \). Both the module \( M^\vee \) and the integer \( d(M) \) are of exceptional interest. It is easy to show that \( M^\vee \) is also a simple module. We would like to finish the paper with a conjectural description of the homologically dual module \( M^\vee \) for topological groups of Kac-Moody type that agrees with the known description for \( p \)-adic groups [9].

Let \( G \) be a topological group of Kac-Moody type as defined in Section 6. We make additional assumptions for simplicity:

1. \( B \) is compact,
2. \( F \) is a \( B \)-ordinary field (so we can choose \( \mu = \mu_B \)),
3. \( (B, N, S) \) is a BN-pair on \( G \),
4. \( A \) is trivial.

Assumption (1) can be achieved for an arbitrary topological group of Kac-Moody group \( G' \) by replacing it with \( G = G'/K' \) where \( K' \) is the kernel of \( (\rho, M) \in \mathcal{M}(A) \). Assumption (3) can be achieved by restricting \( (\rho, M) \) to \( G_0 \).

Let us denote \( \mathcal{H}(B,G/B) \) the space of \( F \)-valued compactly supported \( B \)-bi-invariant functions on \( G \). This space is a subalgebra of the Hecke algebra \( \mathcal{H}(G,F,\mu) \). For each element \( w \) of the Weyl group \( W \) we denote by \( \Theta_w \) the delta-function of the double coset \( BWB \), i.e., \( \Theta_w(x) = 1 \) if \( x \in BWB \) and \( \Theta_w(x) = 0 \) otherwise. Clearly, \( \Theta_w, w \in W \) form an \( F \)-basis of the spherical Hecke algebra \( \mathcal{H}(B,G/B) \).
We should relate the spherical Hecke algebra to the multiparameter Iwahori-
Hecke algebra $\mathbb{H}[q_s, q_s^{-1}]$. The formal variable $q_s, s \in S$ depends only on the
$W$-conjugacy class of $s$: we set $q_s = q_t$ if there exists $w \in W$ such that $s = wtw^{-1}.
Then $\mathbb{H}[q_s, q_s^{-1}]$ is a $\mathbb{Z}[q_s, q_s^{-1}]$-algebra generated by elements $T_s$, for $s \in S$, which
satisfy the following relations:

1. $T_sT_tT_s \ldots = T_sT_tT_s \ldots$ for all $s \neq t \in S$ with the element $st$ of finite
order where each side of the equality contains exactly $|st|$ $T$s.

2. $(T_s - q_s)(T_s + 1) = 0$ for all $s \in S$.

The relation between these two algebras is summarised in the following proposition,
whose proof is standard.

**Proposition 8.3.** The natural homomorphism

$$
\mathbb{H}[q_s, q_s^{-1}] \otimes \mathbb{F}_{\mathbb{Z}[q_s, q_s^{-1}]}, \quad T_s \otimes 1 \mapsto \Theta_s, \quad q_s \mapsto |B : B \cap sBs^{-1}| \cdot 1
$$

is an isomorphism of algebras.

Let us use this isomorphism to define a new involution. We have already seen the
antipode $\sigma(\Theta)(x) = \Theta(x^{-1})$ in Section 8.8. On the level of Iwahori-Hecke algebra the
antipode is a $\mathbb{Z}[q_s, q_s^{-1}]$-linear antihomomorphism of $\mathbb{H}[q_s, q_s^{-1}]$ such that $\sigma(T_s) = T_s$. We define Iwahori-Matsumoto involution (antiinvolution) as a $\mathbb{Z}[q_s, q_s^{-1}]$-linear
homomorphism (antihomomorphism) of $\mathbb{H}[q_s, q_s^{-1}]$ such that

$$
\iota_{IM}(T_s) = -q_sT_s^{-1} \quad (\sigma_{IM}(T_s) = -q_sT_s^{-1}
$$

correspondingly. Observe that the four maps $\text{Id}, \sigma, \sigma_{IM}, \iota_{IM}$ form a Klein four-group. Now we use the notation of Proposition 8.3 to formulate the final conjecture of our paper:

**Conjecture 8.4.** Suppose we are under the additional assumptions (1)-(4) stated
above and $M$ is a simple module in $\mathcal{M}(G)^B$. Then $M^\vee$ is also a simple module in
$\mathcal{M}(G)^B$ and the $\mathcal{H}(B; G/B)$-modules $\Lambda_B \ast \mathcal{F}(M)$ and $\Lambda_B \ast \mathcal{F}(M^\vee)$ are twists of
each other with respect to the Iwahori-Matsumoto involution $\iota_{IM}$.
