Abstract In a recent paper by the author (Chen in JHEP 02:115, 2020), the reduction of Feynman integrals in the parametric representation was considered. Tensor integrals were directly parametrized by using a generator method. The resulting parametric integrals were reduced by constructing and solving parametric integration-by-parts (IBP) identities. In this paper, we furthermore show that polynomial equations for the operators that generate tensor integrals can be derived. Based on these equations, two methods to reduce tensor integrals are developed. In the first method, by introducing some auxiliary parameters, tensor integrals are parametrized without shifting the spacetime dimension. The resulting parametric integrals can be reduced by using the standard IBP method. In the second method, tensor integrals are (partially) reduced by using the technique of Gröbner basis combined with the application of symbolic rules. The unreduced integrals can further be reduced by solving parametric IBP identities.

1 Introduction

One of the most important issues in today’s high energy physics is the calculation of Feynman amplitudes. Generally, Feynman amplitudes are expressed in terms of tensor integrals, that is, Feynman integrals with Lorentz indices. A widely used strategy to calculate tensor integrals is to first do a tensor reduction to write tensor integrals as linear combinations of scalar integrals, and then reduce the scalar integrals by using the integration-by-parts (IBP) method [2–4].

For one-loop integrals, the tensor reduction can be implemented by the well-known Passarino–Veltman reduction [5]. Multiloop tensor integrals can be reduced to scalar integrals by using the projector technique (see e.g. Ref. [6]). Specifically, an amplitude is written as a linear combination of some tensor structures. The coefficient of a tensor structure is extracted by applying a projector to the amplitude. In practice, the tensor structures and the corresponding projectors are process-dependent. A general algorithm can be developed in principle. However, the calculation of the projectors for high-rank tensor integrals, which involves the inversion of a large matrix, is quite cumbersome. Recently, in Refs. [7,8] it was shown that due to the four-dimensional nature of the external states the number of projectors could be much smaller by considering helicity amplitudes. These methods explicitly make use of the structures of the amplitudes for the process under consideration. Hence they break down for a general tensor integral.

An alternative to tensor reduction is to directly parametrize tensor integrals, as was suggested in Ref. [9]. It was suggested in Ref. [10] that it was possible to derive IBP relations directly in the Lee–Pomeransky representation [11]. Parametric integrals could be reduced to master integrals by solving these linear relations. In this paper, we follow a similar approach developed in Ref. [1] (referred to as paper I hereafter). A tensor integral is parametrized by applying a sum of chains of index-shifting operators to a scalar integral. The advan-
tage of this method is that the parametrization can be applied to arbitrary tensor integrals, and can easily be implemented in automatic calculations. The resulting parametric integrals can directly be reduced by solving parametric IBP identities. As was mentioned in paper I, the reduction in the parametric representation was advantageous over the traditional IBP method in several aspects. Comparing with the momentum-space IBP method, fewer IBP identities are generated for a reduction. Symbolic rules can easily be generated in the parametric representation.\(^1\) Furthermore, symmetries of integrals are related to the spacetime dimension through \(\lambda_0 = -\frac{d}{2}\). The measure \(d\Pi^{\left(\alpha\right)} \equiv \prod_{i=1}^{d} dx_i \delta(1 - \sum_j \left|x_j\right|)\), where the sum in the delta function runs over any nontrivial subset of \(\{x_1, x_2, \ldots, x_{n+1}\}\). \(F\) is a homogeneous polynomial of \(x_i\) of degree \(L + 1\), defined by \(F(x) \equiv F(x) + U(x)x_{n+1}\). and \(F\) and \(F\) are Symanzik polynomials, defined by \(U(x) \equiv \text{det} A\), and \(F(x) \equiv U(x) \left(\sum_{i,j=1}^{L} (A^{-1})_{ij} B_i - B_j - C\right)\). In this paper, we define the degree of a parametric integral by \(\Lambda \equiv \sum_{i=1}^{n+1} \lambda_i\).

As is proven in paper I, the parametric integral satisfies the following identities:

\[
0 = \int d\Pi^{\left(n+1\right)} \frac{\partial}{\partial x_i} T^{-\left(n\right)} + \delta_{\lambda_j 0} \int d\Pi^{\left(\alpha\right)} \frac{\partial}{\partial x_i} T^{-\left(n\right)} \bigg|_{x_i = 0},
\]

where \(\delta_{\lambda, 0}\) is the Kronecker delta. We define the index-shifting operators \(R_i, D_i, \) and \(A_i\), with \(i = 1, \ldots, n\), such that

\[
\begin{align*}
R_i I(\lambda_0, \ldots, -\lambda_i, \ldots, \lambda_n) &= (\lambda_i + 1) I(\lambda_0, \ldots, \lambda_i + 1, \ldots, \lambda_n), \\
D_i I(\lambda_0, \ldots, \lambda_i, \ldots, \lambda_n) &= I(\lambda_0, \ldots, \lambda_i - 1, \ldots, \lambda_n), \\
A_i I(\lambda_0, \ldots, \lambda_i, \ldots, \lambda_n) &= \lambda_i I(\lambda_0, \lambda_i, \ldots, \lambda_n), \quad \lambda \notin \mathbb{Z}^-.
\end{align*}
\]

It is understood that

\[
I(\lambda_0, \ldots, -\lambda_i - 1, \ldots, \lambda_n) \equiv \int d\Pi^{\left(n\right)} T^{-\left(n\right)} \bigg|_{x_i = 0} \quad \text{and}
\]

\[
R_i I(\lambda_0, \ldots, -\lambda_i - 1, \ldots, \lambda_n) \equiv 0.
\]

The product of two operators is defined by successive action. That is, \((XY) I(\lambda) \equiv X(Y I(\lambda))\). It is easy to get the following commutation relations:

\[
\begin{align*}
D_i R_j &- R_j D_i = \delta_{ij} j, \\
D_i A_j - A_j D_i &= \delta_{ij} D_i, \\
R_i A_j - A_j R_i &= -\delta_{ij} R_i.
\end{align*}
\]

We formally define operators \(D_{n+1}\) and \(R_{n+1}\), such that \(D_{n+1} I = I\), and \(R'_{n+1} I = (A_{n+1} + 1)(A_{n+1} + 2) \cdots (A_{n+1} + i) I\), with \(A_{n+1} \equiv -(L + 1) A_0 - \sum_{i=1}^{n}(A_i + 1)\). Notice that \(R_{n+1}, D_{n+1}\), and \(A_{n+1}\) do not obey the commutation relations listed above. It is easy to rewrite Eq. (2.3) in the following form:

\[
D_0 \frac{\partial F(R)}{\partial R_i} - D_i \approx 0, \quad i = 1, 2, \ldots, n + 1.
\]

Here we use \(\approx\) instead of \(\equiv\) to indicate that these identities are valid only when they are applied to nontrivial parametric integrals \(I(\lambda)\). It should be noted that \(X_{i0}\) is ill-defined for \(X_{i0} \equiv R_i, D_i, \) or \(A_i\). Thus \(R_i, D_i, \) and \(A_i\) are not linear operators on the linear space of parametric Feynman integrals. Notice that \(R_{n+1}\) does not commute with \(R_i\) for
We assume that $R_{n+1}$ in $\mathcal{F}(R)$ is to the right of $U(R)$. Explicitly, we have
\begin{align}
0 & \approx D_0 U(R) - 1, \\
0 & \approx D_0 \left( \frac{\partial F(R)}{\partial R_i} + \frac{\partial U(R)}{\partial R_i} - R_{n+1} \right) - D_i.
\end{align}

Equation (2.10a) is consistent with the ordering of Method II, to be described in the next section, the ordering of monomials in Eq. (2.13) is consistent with the ordering of the corresponding parametric integrals. Symbolic rules can easily be generated out of Eq. (2.13) in this case. For example, for the tadpole integral with a mass $m$, we have a symbolic IBP identity $m^2 R_1 - (A_0 + A_1 + 1) \approx 0$. According to the ordering, $R_1$ is superior to $A_0$ and $A_1$, so this equation is solved by $R_1 \approx \frac{1}{m^2}(A_0 + A_1 + 1)$. Correspondingly, we have the symbolic rule $I(-\frac{d}{2}, i) = \frac{2i-d}{2m^2} I(-\frac{d}{2}, i-1)$.

### 3 Reduction of tensor integrals

According to the derivation in paper I, a tensor integral can be parametrized by

$$M^{\mu_1 \mu_2 \cdots \mu_r}_{\nu_1 \nu_2 \cdots \nu_s} = \pi^{-\frac{d}{2}} e^{(\Lambda_i)} \left[ \sum_{\nu_1}^{\nu_s} \delta_{\mu_1 \mu_2} \cdots \delta_{\mu_1 \mu_r} i(-\frac{d}{2}, \lambda_1, \lambda_2, \ldots, \lambda_n) \right]_{\mu^{\mu_1 \mu_2} \cdots \mu^{\mu_r} \nu^{\nu_1 \nu_2} \cdots \nu^{\nu_s}}.$$  

(3.1)

where the operator

$$P_i^\mu (p) \equiv -\frac{\partial}{\partial p_{i,\mu}} - \tilde{B}_i^\mu + \frac{1}{2} \sum_{j=1}^L \tilde{A}_{ij} p_j^\mu,$$

(3.2)

where $\tilde{A}_{ij} \equiv D_0 U(A_1)^{-1}_{ij}$ and $\tilde{B}_i^\mu \equiv \sum_{j=1}^{L} \tilde{A}_{ij} B_j^\mu$. Thus a tensor integral is parametrized by a linear combination of parametric integrals of the form

$$M_i = f_i(\tilde{A}, \tilde{B}) I(\lambda_0, \lambda_1, \ldots, \lambda_n).$$  

(3.3)

Obviously $\tilde{A}(x)$ is of degree $L - 1$ in $x$, and $\tilde{B}(x)$ is of degree $L$ in $x$. Due to the $\tilde{B}$ term in Eq. (3.2), the highest degree of parametric integrals for a $L$-loop rank-$r$ tensor integral is $L r$, which increases rapidly with $r$ for multiloop integrals. Consequently, the linear system to be solved is very large for a high-rank tensor integral. A solution to this problem is to directly reduce $f_i$ in Eq. (3.3) without substituting the explicit forms of the $\tilde{B}$. A is as derived in Appendix A, the $\tilde{B}$ satisfy the following equations:

$$\sum_{j=1}^{L} \tilde{B}_j I(\lambda_0, \lambda_1, \ldots, \lambda_n) = 0.$$  

(3.4)

Based on these equations, we trade the reduction of the $f_i$ in Eq. (3.3) to a problem of polynomial reduction. The difficulty is that in Eq. (3.4) the $D$ do not commute with the $\tilde{B}$. We provide two methods to solve this problem, as will be described in the next two subsections.

2 This expression is consistent with the parametrization used in Ref. [16].

3 The $\tilde{A}$ term is less problematic, so we do not need to pay much attention to it.
3.1 Method I

In this subsection, by introducing some auxiliary parameters, we will show that the $\tilde{B}$ can be expressed as linear combinations of the $D$, which are of degree $-1$ (according to the prescription at the end of Sect. 2). Consequently, the corresponding parametric integrals are of lower degrees. First, we need to extend the definition of the parametric integrals to include integrals with negative indices. We define [10]

$$I(\lambda_0, \lambda_1, \ldots, \lambda_n) \equiv \lim_{\lambda_i \to -\infty} I(\lambda_0, \lambda_1, \ldots, \lambda_i, \lambda_{i+1}, \ldots, \lambda_n)$$

$$= (-1)^{m-1} \prod_{j \neq i} \Gamma(-\lambda_i) \times \int d\Pi^{(n)} \left[ \frac{\partial^{m-1} \varphi^{(0)}}{\partial \lambda_i^{n-1}} \right]_{\lambda_i = 0} \prod_{j \neq i} x_j^{\lambda_j}, \quad m \in \mathbb{N}. \quad (3.5)$$

It is easy to see that this definition is consistent with Eq. (2.9). The definition of the degree of an integral should also be modified. We define the degree of a nonnegative index $\lambda_i$ by $d_i \equiv \lambda_i$, and the degree of a negative index $\lambda_i$ by $d_i \equiv -1 - \lambda_i$. The degree of an integral is defined by $\Lambda \equiv \sum_{i=1}^n d_i$.

Let $a_{ij}$ and $b_{ij}$ be the solutions of

$$\sum_j b_{ij} \frac{\partial A(R)}{\partial R_j} = 0, \quad (3.6a)$$
$$\sum_j a_{ij} \frac{\partial B(R)}{\partial R_j} = 0, \quad (3.6b)$$

where $A$ and $B$ are defined in Sect. 2 (below Eq. (2.1)). Solutions of these two equations may be linearly dependent. We denote those linearly dependent solutions by $c_{ij}$. By default, we assume that these solutions are excluded from $a_{ij}$ and $b_{ij}$.

For brevity, we denote

$$\frac{\partial}{\partial a_i} \equiv \sum_j a_{ij} \frac{\partial}{\partial R_j}, \quad D_{a_i} \equiv \sum_j a_{ij} D_j, \quad (3.7a)$$
$$\frac{\partial}{\partial b_j} \equiv \sum_j b_{ij} \frac{\partial}{\partial R_j}, \quad D_{b_j} \equiv \sum_j b_{ij} D_j, \quad (3.7b)$$
$$\frac{\partial}{\partial c_i} \equiv \sum_j c_{ij} \frac{\partial}{\partial R_j}, \quad D_{c_i} \equiv \sum_j c_{ij} D_j. \quad (3.7c)$$

$B^\mu$ is of the form $\sum_u B_{iu} Q_u^\mu$, where $Q_u^\mu$ are the (linearly independent) external momenta. Similarly we have $\tilde{B}^\mu_i = \sum_u B_{iu} Q_u^\mu$. By virtue of Eq. (3.4), we have

$$- 2 \sum_{u,v,j} Q_u \cdot Q_v \frac{\partial B_{iu}}{\partial b_j} \tilde{B}_{jv} + \frac{\partial C}{\partial b_i} + D_{b_i} \approx 0, \quad (3.8a)$$

$$\sum_{j,k} \frac{\partial A_{jk}}{\partial a_i} \tilde{B}_{j} \cdot \tilde{B}_{k} + D_0 A_0 \frac{\partial U}{\partial a_i} + \frac{\partial C}{\partial a_i} + D_{a_i} \approx 0, \quad (3.8b)$$
$$\frac{\partial C}{\partial c_i} + D_{c_i} \approx 0. \quad (3.8c)$$

Generally speaking, the matrix $\frac{\partial B_{iu}}{\partial b_j}$ is not invertible. However, we can always make it invertible by introducing some auxiliary parameters $x_{n+1}, x_{n+2}, \ldots$ through the transformation $B_{iu} \rightarrow B_{iu} + \sum_k c_k x_k$, where $c_k$ are some constants. This is equivalent to adding some auxiliary propagators of the form $\sum c_i l_i \cdot Q_i$. We denote the inverse of $\frac{\partial B_{iu}}{\partial b_j}$ by $\beta_{ju,k}$. That is,

$$\sum_k \beta_{iu,k} \frac{\partial B_{ju}}{\partial b_k} = \delta_{ij} \delta_{uv}. \quad (3.9)$$

Similarly, we can always make the Gram matrix $Q_u \cdot Q_v$ invertible by introducing some auxiliary external momenta. (Notice that we assume that the $Q$ are linearly independent.) Then Eq. (3.8a) is solved by

$$\tilde{B}_{iu} \approx \frac{1}{2} \sum_{j,v} g_{uv} \beta_{iv,j} \left( \frac{\partial C}{\partial b_j} + D_{b_j} \right) \equiv \bar{B}_{iu}, \quad (3.10)$$

where $g_{uv}$ is the inverse of $Q_u \cdot Q_v$.

Since the $\tilde{B}$ are of degree $L$, while the $D$ (hence the $\tilde{B}$) are of degree $-1$, by expressing $\bar{B}_{iu}$ in terms of $\tilde{B}_{iu}$, the corresponding parametric integrals are of much lower degrees. However, we cannot directly apply Eq. (3.10) to a chain of $\tilde{B}$, because the $\tilde{B}$ do not commute with the $\tilde{B}$. It is easy to get the commutation relations

$$[\tilde{B}_{iu}, \tilde{B}_{jv}] = \frac{1}{2} g_{uv} \tilde{A}_{ij}, \quad (3.11a)$$
$$[\tilde{B}^\mu_i, \tilde{B}^\nu_j] = \frac{1}{2} \sum_{u,v} g_{uv} Q_u^\mu Q_v^\nu \tilde{A}_{ij} \equiv \frac{1}{2} \eta^{uv} \tilde{A}_{ij}. \quad (3.11b)$$

By virtue of these commutation relations, together with Eq. (3.10), it can be shown that the operator $P^\mu_i$ defined in Eq. (3.2) can be replaced by (for the proof, see Appendix B)

$$P^\mu_i \approx - \frac{\partial}{\partial \tilde{B}_{i,\mu}} - \tilde{B}^\mu_i + \frac{1}{2} \sum_{j} \tilde{A}_{ij} \tilde{p}_j^\mu, \quad (3.12)$$

where $\tilde{p}_i$ are vectors such that $\tilde{p}_i \cdot Q_j = 0$. The $\tilde{B}$ are free of $D_0$, and thus will not shift the spacetime dimension. Due to the definition of $\beta_{ij,k}$, the $\tilde{B}$ commute with the $\tilde{A}$. Thus by applying operators $P^\mu_i$, tensor integrals are parametrized by integrals of the form $f(\tilde{A}) f(-\frac{d}{2}, \ldots)$. It remains to reduce chains of $\tilde{A}$. 

\[ \square \] Springer
Similar to \( \frac{\partial B_j}{\partial b_j} \), the matrix \( \frac{\partial A_{jk}}{\partial a_k} \) can be made invertible by introducing some auxiliary parameters through the transformation \( A_{ij} \rightarrow A_{ij} + \sum_k c_k x_k \). This is equivalent to adding some auxiliary propagators of the form \( \sum_{ij} c_{ij} l_i l_j \). Let \( \alpha_{ij,k} \) be the matrix such that

\[
\sum_k \alpha_{ij,k} \frac{\partial A_{mn}}{\partial a_k} = \frac{1}{2} \left( \partial^{im} \delta^{jn} + \partial^{jn} \delta^{im} \right).
\]  

(3.13)

As is derived in Appendix C, Eq. (3.8b) is solved by

\[
\tilde{A}_{ij} \left( A_0 + \frac{E}{2} \right) \approx -\hat{B}_i \hat{B}_j - \sum_k \alpha_{ij,k} \left( D_{ak} + \frac{\partial C}{\partial a_k} \right) \equiv \tilde{A}_{ij},
\]  

(3.14)

where \( \hat{B}^k_j \equiv \sum_n \hat{B}_{lu} Q^k_{lu} \), and \( E \) is the number of the external momenta. We have the following commutation relation:

\[
[\tilde{A}_{ij}, \tilde{A}_{kl}] \approx \frac{1}{2} \left( \tilde{A}_{ik} \tilde{A}_{jl} - \tilde{A}_{il} \tilde{A}_{kj} \right) - \tilde{A}_{ij} \tilde{A}_{kl}.
\]  

(3.15)

By virtue of Eqs. (3.14) and (3.15), we get

\[
\begin{align*}
\tilde{A}_{i_1 j_2} \tilde{A}_{i_3 j_4} \cdots \tilde{A}_{i_n j_n} & \approx \tilde{A}_{i_1 j_2} \tilde{A}_{i_3 j_4} \cdots \tilde{A}_{i_n j_n} \left( A_0 + \frac{E}{2} \right) \\
& - \frac{1}{2} \left( \tilde{A}_{i_1 i_2} \tilde{A}_{j_1 j_2} + \tilde{A}_{i_1 j_2} \tilde{A}_{i_2 j_1} \right) \tilde{A}_{i_3 j_3} \cdots \tilde{A}_{i_n j_n} \\
& - \frac{1}{2} \left( \tilde{A}_{i_1 i_2} \tilde{A}_{j_1 j_2} + \tilde{A}_{i_1 j_2} \tilde{A}_{i_2 j_1} \right) \tilde{A}_{i_3 j_3} \cdots \tilde{A}_{i_n j_n} \\
& \cdots \\
& - \frac{1}{2} \left( \tilde{A}_{i_1 i_n} \tilde{A}_{j_1 j_n} + \tilde{A}_{i_1 j_n} \tilde{A}_{i_n j_1} \right) \tilde{A}_{i_2 j_2} \tilde{A}_{i_3 j_3} \cdots \tilde{A}_{i_{n-1} j_{n-1}} \\
& = \Delta_{i_1 i_2 \cdots i_n}^{j_1 j_2 \cdots j_n}.
\end{align*}
\]  

(3.16)

The proof of this equation can be found in Appendix D. A chain of \( \tilde{A} \) can further be reduced to a sum of chains of \( \tilde{A} \) by solving this equation. Currently we have not worked out the general solution to this equation yet. However, this is not a problem in practice, because this equation system is small in size and can easily be solved by brute force.

After applying Eq. (3.12) and solutions of Eq. (3.16), tensor integrals are parametrized by scalar integrals defined in dimension \( d \). The resulting scalar integrals can be reduced by solving IBP identities free of dimensional shift, which can be obtained by multiplying both sides of Eqs. (3.10) and (3.14) with \( A_{ij} \). Together with Eq. (3.8c), we have

\[
\begin{align*}
\frac{\partial C}{\partial c_i} + D_{ci} & \approx 0, \\
\sum_j \bar{B}_{ju} A_{ij} & \approx B_{iu}.
\end{align*}
\]  

(3.17a)

(3.17b)

These identities are nothing but the correspondences of the momentum-space IBP identities [13] in the parametric representation [14].

As a byproduct, Eq. (3.10) provides a method to construct differential equations in the parametric representation without shifting the spacetime dimension. Let \( s \) be a kinematic variable, and assume that \( A_{ij} \) is free of \( s \). Then we have

\[
\begin{align*}
\frac{\partial}{\partial s} = & -D_0 \frac{\partial F}{\partial s} \\
= & -D_0 \frac{\partial F}{\partial s} \\
= & -D_0 \left( \sum_{i,j,u,v} A_{ij}^{-1} B_{iu} B_{ju} \frac{\partial Q_u \cdot Q_v}{\partial s} \\
& + 2 \sum_{i,j,u,v} Q_u \cdot Q_v A_{ij}^{-1} B_{iu} \frac{\partial B_{ju}}{\partial s} + \frac{\partial C}{\partial s} \right) \\
& - \sum_{i,j,u,v} \bar{B}_{iu} B_{ju} \frac{\partial Q_u \cdot Q_v}{\partial s} - 2 \sum_{i,j,u,v} Q_u \cdot Q_v \bar{B}_{iu} \frac{\partial B_{ju}}{\partial s} + \frac{\partial C}{\partial s}.
\end{align*}
\]  

(3.18)

3.2 Method II

In this subsection, we will show how to reduce tensor integrals without introducing auxiliary parameters by using the technique of Gröbner basis. In principle, we can generate a Gröbner basis [17] out of Eqs. (2.10a) and (3.4)\(^4\) (for a brief introduction to Gröbner bases and relevant topics, see e.g. Ref. [18]). Then the reduction of Feynman integrals is just a matter of polynomial reduction. The idea to use Gröbner bases to reduce Feynman integrals was first suggested by Ref. [19]. The method of the s-basis [20,21], a variant of the Gröbner basis, was implemented in the early version of FIRE [22]. However, experience shows that generating a Gröbner basis for a noncommutative algebra is extremely time-consuming, which makes it less efficient for the reduction of Feynman integrals in practice. In this subsection, we try to solve this problem by converting the problem of a noncommutative algebra to the one of a commutative algebra. Though the Gröbner basis for the commutative algebra is not the full Gröbner basis for the corresponding noncommutative algebra, it can be used to greatly simply integrals to be reduced in practice.

Since \( \frac{\partial A}{\partial \bar{R}_i}, \frac{\partial A}{\partial \bar{R}_j}, \) and \( \frac{\partial C}{\partial \bar{R}_i} \) are constants, the l.h.s. of Eq. (3.4) is a polynomial of \( \bar{B}^k_j \) and \( D_{1i} \), except for the \( \frac{\partial U}{\partial \bar{R}_i} \) term. By

\(^4\) Here Eq. (2.10a) is considered because \( D_0 U \) contributes to \( \bar{B}^k_j \). We notice that the \( B \) are not uniquely determined. It is easy to see that for a shift \( \delta \hat{b}^k_j \) of the loop momenta the corresponding shift of \( \bar{B}^k_j \) is \( \delta \bar{B}^k_j = D_0 U \delta \hat{b}^k_j \).
using Eq. (2.10) and the identity $D_j f(R) - f(R) D_j = \frac{\partial f(R)}{\partial R_i}$, we can write Eq. (3.4) in the following form:

$$\sum_{j,k=1}^L \frac{\partial A_{ij}}{\partial R_i} \tilde{B}_j \cdot \tilde{B}_k - 2 \times \sum_{j=1}^L \frac{\partial B_j}{\partial R_i} \tilde{B}_j + \tilde{C} + A_0 D_1 (D_0 U - 1) + D_1 (D_0 U + 1) \approx 0. \tag{3.19}$$

For simplicity, we denote $y_0 \equiv D_0 U, \tilde{B}_i^\mu \equiv \sum_j y_{ij} Q^\mu_j, z_i \equiv D_i, and w_i \equiv A_0 D_i$. Equations (2.10a) and (3.19) give rise to polynomial equations in $y, z, and w$. Since $z$ and $w$ do not commute with $y$, we assume that $z$ and $w$ are always to the left of $y$. The noncommutativity problem can be solved by avoiding multiplying $y$ by $z$ or $w$ from the right-hand side. When we try to generate a Gröbner basis by using the Buchberger algorithm [17], terms of the form $y_i z_j$ or $y_i w_j$ may arise, which are in contradiction with the ordering we use. In order to avoid this kind of terms, we multiply monomials free of $z$ and $w$ by an auxiliary variable $z_0$, and add to the polynomial equation system following equations:

$$z_i z_j = w_i w_j = z_i w_j = 0. \tag{3.20}$$

Terms of the form $y_i z_j$ (or $y_i w_j$) arise only when we multiply an equation $f \approx 0$ by $z_j$ (or $w_j$). However, the l.h.s. of the obtained equation $f z_j \approx 0$ (or $f w_j \approx 0$) is immediately replaced by zero due to Eq. (3.20) (Notice that each monomial of $f$ is linear in $z$ or $w$.) Thus we can identify $y_i z_j$ (or $y_i w_j$) with $z_j y_i$ (or $w_j y_i$), since it never appears in practice. Consequently, the Gröbner basis for the polynomial equation system can be generated by using the Buchberger algorithm assuming all the variables are commutative. Finally we will remove polynomial equations in Eq. (3.20) from the generated Gröbner basis. One may use some other algorithms to generate the Gröbner basis. Then terms of the form $y_i z_j$ or $y_i w_j$ may not be eliminated at the intermediate steps. However, as far as we only pick those equations linear in $z$ or $w$ at the final step, the obtained basis is valid. Because all polynomial equations are homogeneous in $z$ and $w$, equations of higher degrees in $z$ and $w$ never affect those linear in $z$ or $w$. There is another type of identities. Generally the $y$ are not independent. They are related to each other through the relation

$$y_i = y_i (R). \tag{3.21}$$

In practice, we first eliminate $R_i$ from Eq. (3.21), and add the resulting equations to the polynomial equation system.

After obtaining the Gröbner basis, integrals of the form in Eq. (3.3) can be reduced by reducing the polynomial $f_j$ with respect to the basis. The resulting polynomials may contain terms of the form $w_j y_j y_k \cdots I(\lambda)$. This kind of terms can be further reduced by replacing them by

$$w_j y_j y_k \cdots I(\lambda) = A_0 \sum_{\alpha} \frac{\partial y_{\alpha j}}{\partial \alpha} \frac{\partial y_{\alpha k}}{\partial \alpha} \frac{\partial y_{\alpha m}}{\partial \alpha} I(\lambda) + y_j y_k \cdots w_i I(\lambda). \tag{3.22}$$

$A_0$ in the above equation can be replaced by its eigenvalue. $rac{\partial y_{\alpha j}}{\partial \alpha}$ and $y_j y_k \cdots w_i$ can further be reduced with respect to the Gröbner basis. Terms of the form $z_j y_j y_k \cdots$ can be reduced similarly.

### 4 Examples

As an example, we consider the two-loop massless sunset diagram

$$I_1 \left( \frac{d}{2}, \lambda_1, \lambda_2, \lambda_3 \right) = \frac{e^{i \pi (\lambda_1 + \lambda_2 + \lambda_3)}}{(2\pi)^d} \times \int d^d l_1 d^d l_2 \frac{1}{l_1^{(1+\lambda_1)} l_2^{(1+\lambda_2)} (l_1 + l_2 + p)^{2(1+\lambda_3)}}, \tag{4.1}$$

with $p^2 = 1$. We first try to reduce the corresponding tensor integrals by using Method II. The polynomial $\mathcal{F}(R)$ for this integral is

$$\mathcal{F}_1(R) = -R_1 R_2 R_3 + R_1 R_2 R_4 + R_1 R_3 R_4 + R_2 R_3 R_4. \tag{4.2}$$

The operator $\tilde{B}_i^\mu$ is

$$\tilde{B}_i^\mu = D_0 \left( \begin{array}{c} R_2 R_3 \\ R_1 R_3 \end{array} \right) p^\mu \equiv \left( \begin{array}{c} y_2 \\ y_1 \end{array} \right) p^\mu. \tag{4.3}$$

We define $y_3 \equiv D_0 U = D_0 (R_1 R_2 + R_1 R_3 + R_2 R_3)$. Following the algorithm described in Sect. 3.2, we first generate a Gröbner basis out of Eq. (3.19). All the calculations can be done by using Mathematica. The Gröbner basis is generated with the built-in function GroebnerBasis. A degree-reverse-lexicographic order is used. To reveal the correct degree in $R_i$, we introduce another auxiliary variable $x$ and rescale the variables by $z_0 \rightarrow x z_0$, and $y_i \rightarrow x^{L-1} y_i$. Experiences show that it is less efficient to generate a full basis. In practice, we exclude polynomials with degrees larger than 4. In Mathematica, this can be implemented by representing $y_i$ by a pattern $y[_-]$, and setting $y/\text{ComplexInfinity}$/;n>4. Finally, we get a basis of size 12, among which some are
The generated basis is complete in the sense that a monomial \( y_1^{j_1} y_2^{j_2} y_3^{j_3} \) can be reduced with respect to the Gröbner basis as far as one of the following conditions is satisfied: \( i_1 > 1, i_2 > 1, \) or \( i_3 > 0 \). The polynomial reduction can be carried out by using the built-in function \texttt{PolynomialReduce}.

Though the basis is complete in this example, the reduction is not. The reason for this is that when we use Eq. (3.22) to reduce terms of the form \( w_i y_j y_k \ldots \), we get terms of the form \( \partial y_j(R) \), which is not a polynomial in the \( y \).

\[
A = \left( \begin{array}{ccc} R_1 + R_3 & R_3 & R_3 \\ R_3 & R_2 + R_3 \end{array} \right),
\]

\[
B^\mu = \left( \begin{array}{c} R_3 + \frac{1}{2} R_5 \\ R_3 + \frac{1}{2} R_4 \end{array} \right) p^\mu,
\]

\[
\tilde{A} = \frac{1}{2} \begin{pmatrix} -2D_4^2 - 2D_1 & -2D_4 D_5 + D_1 + D_2 - D_3 + 2D_4 + 2D_5 - 1 \\ -2D_4 D_5 + D_1 + D_2 - D_3 + 2D_4 + 2D_5 - 1 & -2D_4^2 - 2D_2 \end{pmatrix},
\]

\[
\tilde{B}^\mu = \left( \begin{array}{c} D_5 \\ D_4 \end{array} \right) p^\mu.
\]

The unreduced integrals can further be reduced by applying symbolic rules. Symbolic rules are derived by solving symbolic IBP identities generated by Eq. (2.13). Excluding some redundant rules, and considering the symmetries under permutations of indices, we get the following rules:

\[
I_1(i_0, i_1, i_2, i_3) = \frac{I_1(i_0, i_1 - 1, i_2, i_3)}{i_1 (i_0 + i_1 + 1)} \times \left[ (i_1 - 1)^2 + (2i_2 + 2i_3 + 7)(i_1 - 1) + 6i_0^2 + i_2^2 + i_3^2 + (5(i_1 - 1) + 5i_2 + 5i_3 + 17)i_0 + 7i_2 + 2i_2i_3 + 7i_3 + 12 \right], \quad i_1 > 0,
\]

\[
I_1(i_0, i_1, i_2, i_3) = I_1(i_0, i_2, i_1, i_3), \quad i_2 > 0.
\]

Dimensional recurrence relations can be derived by explicitly solving IBP identities. We have

\[
I_1(i_0, 0, 0, 0) = \frac{(i_0 + 2)I_1(i_0 + 1, 0, 0, 0)}{6(2i_0 + 3)(3i_0 + 4)(3i_0 + 5)}.
\]

Obviously these rules are complete in the sense that any integral of the form \( I_1(i_0, i_1, i_2, i_3) \) can be reduced to the master integral \( I(-\frac{d}{2}, 0, 0, 0) \) by applying these rules.

Alternatively, we can do the reduction by using Method I. Since the first equation in Eq. (3.6) has no solution, we need to extend the polynomial \( F_1 \) by introducing two auxiliary parameters, which is equivalent to introducing two auxiliary propagators \( l_1 \cdot p \) and \( l_2 \cdot p \). We denote

\[
I_2(-\frac{d}{2}, \lambda_1, \lambda_2, \lambda_3, \lambda_4, \lambda_5) = \frac{\mu(\sum_{i=1}^{\lambda_1})}{(2\pi)^d} \int d^d l_1 d^d l_2 \times \left( \frac{1}{l_1^{2(\lambda_1+1)}(l_1 + l_2 + p)^{2(\lambda_1+2)}(l_1 \cdot p)^{\lambda_1 + \lambda_4}(l_1 \cdot p)^{\lambda_1 + \lambda_5}} \right).
\]

The polynomials \( A, B, \tilde{A} \) and \( \tilde{B} \) for this integral are

\[
\frac{1}{(2\pi)^d} \int d^d l_1 d^d l_2 \frac{\mu(\sum_{i=1}^{\lambda_1})}{l_1^{2(\lambda_1+1)}(l_1 + l_2 + p)^{2(\lambda_1+2)}(l_1 \cdot p)^{\lambda_1 + \lambda_4}(l_1 \cdot p)^{\lambda_1 + \lambda_5}}.
\]

Then tensor integrals can be parametrized by using the method described in Sect. 3.1. For example, we have

\[
\frac{1}{(2\pi)^d} \int d^d l_1 d^d l_2 \frac{\mu(\sum_{i=1}^{\lambda_1})}{l_1^{2(\lambda_1+1)}(l_1 + l_2 + p)^{2(\lambda_1+2)}(l_1 \cdot p)^{\lambda_1 + \lambda_4}(l_1 \cdot p)^{\lambda_1 + \lambda_5}}.
\]
+ \mathcal{I}_2 \left( -\frac{d}{2}, -1, 0, 0, -1, -1 \right) + \mathcal{I}_2 \left( -\frac{d}{2}, 0, -1, 0, -1, -1 \right) \\
- \mathcal{I}_2 \left( -\frac{d}{2}, 0, 0, -1, -1, -1 \right) \tag{4.18} \\
+ 2 \mathcal{I}_2 \left( -\frac{d}{2}, 0, 0, 0, -2, -1 \right) + 2 \mathcal{I}_2 \left( -\frac{d}{2}, 0, 0, 0, -1, -2 \right) \\
- \mathcal{I}_2 \left( -\frac{d}{2}, 0, 0, 0, -1, -1 \right). \tag{4.19}

It is easy to check that this result is consistent with the one obtained by using the standard tensor-reduction method. The resulting scalar integrals can further be reduced by solving parametric IBP identities. The number of independent symbolic rules are those with $\lambda \leq 4$. The degrees of the parametric integrals are provided. Based on these equations, two methods to reduce the degrees of parametric integrals are provided.

Contrary to the first example, the generated symbolic rules for the double-box integral are incomplete. We denote a scalar integral by

$$
\mathcal{I}_3 \left( \frac{d}{2}, \ldots, \lambda_7 \right) \equiv \frac{d^{\ldots} \delta_{\lambda_1, \lambda_2}^\ldots}{\pi^d} \int d^d l_1 d^d l_2 \\
\left( \frac{l_1^2 (l_1 + k_1)^2 (l_1 - k_2)^2 (l_1 + l_2 + k_1)^2 (l_1 + l_2 - k_2)^2 (l_1 + l_2 - k_2 - k_3)^2}{(l_1 + l_2 + k_1)^2 (l_1 + l_2 - k_2)^2 (l_1 + l_2 - k_2 - k_3)^2 (l_1 + l_2 - k_2 - k_3)^3} \right) \mathcal{I}_1 l_1 l_2 l_3.
$$

Integrals that cannot be reduced by applying the obtained symbolic rules are those with $\lambda_4 = \lambda_5 = \lambda_6 = \lambda_7 = 0$. These unreduced integrals can easily be reduced by solving parametric IBP identities. The number of independent IBP identities to be solved is much smaller than that in the traditional momentum-space IBP method. This is because the number of unreduced scalar integrals in the former is much smaller. For example, since only those integrals with $\lambda_4 = \lambda_5 = \lambda_6 = \lambda_7 = 0$ cannot be reduced by applying the symbolic rules, there are only dozens of unreduced integrals with degree 5 in the top topology. However, there are more than one thousand momentum-space integrals with degree 5.

To validate the algorithm, we reduced the amplitudes for the QCD corrections to the Higgs two-photon decay by using both methods. The result was consistent with the one obtained by combining the tensor reduction with the traditional IBP method.

5 Summary

In this paper, the reduction of tensor integrals is considered. Following the method developed in paper I, a tensor integral is parametrized by applying a sum of chains of operators $\bar{A}$ and $\bar{B}$ to a scalar integral (cf. Eq. (3.11)). Because the $\bar{B}$ are of degree $L$, the resulting parametric integrals are of high degrees for multiloop high-rank tensor integrals. We show that polynomial equations for the $\bar{B}$ can be constructed (cf. Eq. (3.4)). Based on these equations, two methods to reduce the degrees of parametric integrals are provided.

In the first method, by introducing some auxiliary parameters, we show that the $\bar{B}$ can be traded by the $\bar{B}$ (cf. Eqs. (3.10) and (3.12)), and the $\bar{A}$ can be traded by the $\bar{A}$ (cf. Eq. (3.16)). The corresponding parametric integrals are of much lower degrees. The parametrizing result is consistent with the one obtained by using the tensor-reduction method. However, the former is much easier to carry out for high-rank tensor integrals. The resulting parametric integrals can be reduced by solving dimensional-shift-free IBP identities (cf. Eq. (3.17)).

In the second method, a Gröbner basis is generated out of these polynomial equations of $\bar{B}$. Tensor integrals are partially reduced by using this basis. The unreduced integrals can further be reduced by solving parametric IBP identities combining with the application of symbolic rules. By virtue of the positivity of the indices, symbolic rules can easily be
generated. The number of independent parametric IBP identities to be solved is much smaller than that in the regular IBP method.

Appendix A: Derivation of Eq. (3.4)

For simplicity, we use a center dot to denote both the inner product of two vectors and the product of two matrices. By using the identity \( \frac{\partial A^\dagger}{R_i} = -A^{-1} \cdot \frac{\partial A}{R_i} \cdot A^{-1} \), Eq. (2.10) leads to

\[
D_0 \frac{\partial U}{\partial R_i} R_{n+1} - D_i \approx -D_0 \frac{\partial F}{\partial R_i} = \frac{\partial U}{\partial R_i} (C - B \cdot A^{-1} \cdot B)
\]

\[
+D_0 U \left( B \cdot A^{-1} \cdot \frac{\partial A}{\partial R_i} \cdot A^{-1} \cdot B + \frac{\partial C}{\partial R_i} \right)
\]

\[
\approx -D_0 F D_0 \frac{\partial U}{\partial R_i} + \tilde{B} \cdot \frac{\partial A}{\partial R_i} \cdot \tilde{B}
\]

\[
- \frac{\partial B}{\partial R_i} \cdot \tilde{B} + \frac{\partial C}{\partial R_i} \cdot \tilde{B}.
\]

(A.1)

In the last step of the above equation, we have replaced \( D_0 U \) by 1 or vice versa. For the first term in the last line, we have

\[
- D_0 F D_0 \frac{\partial U}{\partial R_i} = -D_0(F - U R_{n+1}) D_0 \frac{\partial U}{\partial R_i}
\]

\[
\approx (A_0 - 1) D_0 \frac{\partial U}{\partial R_i} + R_{n+1} D_0 \frac{\partial U}{\partial R_i}
\]

\[= (A_0 - 1) D_0 \frac{\partial U}{\partial R_i} + D_0 \frac{\partial U}{\partial R_i} (R_{n+1} + 2)
\]

\[= (A_0 + 1) D_0 \frac{\partial U}{\partial R_i} + D_0 \frac{\partial U}{\partial R_i} R_{n+1}
\]

\[= D_0 A_0 \frac{\partial U}{\partial R_i} + D_0 \frac{\partial U}{\partial R_i} R_{n+1}.
\]

(A.2)

Combining the above equations we get

\[
\hat{B} \cdot \frac{\partial A}{\partial R_i} \cdot \hat{B} = 2 \frac{\partial B}{\partial R_i} \cdot \hat{B} + D_0 A_0 \frac{\partial U}{\partial R_i} + \frac{\partial C}{\partial R_i} + D_i \approx 0.
\]

(A.3)

Appendix B: Proof of Eq. (3.12)

We first define

\[
B_i^{\mu}(q') \equiv \left( \frac{\partial}{\partial q_{i,\mu}'} + \tilde{B}_i^{\mu} + \frac{1}{2} \sum_{i'} \hat{A}_{i i'} q_i{''}_{i'j} \right),
\]

(B.1)

where \( q' \) are vectors defined in the linear space generated by the external momenta \( Q \). We will show that

\[
\hat{B}_i^{\mu} \cdots \hat{B}_i^{\mu} \hat{B}_i^{\mu} \approx \left[ B_i^{\mu}(q') \cdots B_i^{\mu}(q') B_i^{\mu}(q') \right]_{q'=0}.
\]

(B.2)

This equation can easily be proved by iteration. By virtue of Eq. (3.10), it holds when \( n = 1 \). Suppose that this equation holds for \( n = N \), then we have

\[
\left[ B_i^{\mu}(q') \cdots B_i^{\mu}(q') B_i^{\mu}(q') \right]_{q'=0} = B_i^{\mu} \cdots B_i^{\mu} B_i^{\mu} \sum_{i=1}^{n} \hat{A}_{ij}^{\mu} (p_j^{\mu} - q_j^{''})
\]

\[
+ \frac{1}{2} \sum_{j=1}^{n} \hat{A}_{ij}^{\mu} \sum_{j=1}^{n} \left( B_i^{\mu} \cdots B_i^{\mu} B_i^{\mu} \cdots B_i^{\mu} \hat{A}_{ij}^{\mu} (p_j^{\mu} - q_j^{''}) \right)_{q'=0}
\]

\[
= B_i^{\mu} \cdots B_i^{\mu} B_i^{\mu} \sum_{i=1}^{n} \hat{A}_{ij}^{\mu} (p_j^{\mu} - q_j^{''}) + \frac{1}{2} \sum_{j=1}^{n} \left( B_i^{\mu} \cdots B_i^{\mu} B_i^{\mu} \cdots B_i^{\mu} \hat{A}_{ij}^{\mu} (p_j^{\mu} - q_j^{''}) \right)_{q'=0}
\]

\[
= B_i^{\mu} \cdots B_i^{\mu} B_i^{\mu} \hat{B}_i^{\mu} + \frac{1}{2} \sum_{j=1}^{n} \left( B_i^{\mu} \cdots B_i^{\mu} B_i^{\mu} \cdots B_i^{\mu} \hat{A}_{ij}^{\mu} (p_j^{\mu} - q_j^{''}) \right)_{q'=0}.
\]

(B.3)

In the last line we have used the commutation relation Eq. (3.11b). Then, by using Eq. (B.2), we have

\[
P_i^{\mu} \approx -\frac{\partial}{\partial p_i,\mu} - \frac{\partial}{\partial q_{i,\mu}'} - \hat{B}_i^{\mu} + \frac{1}{2} \sum_{j=1}^{L} \hat{A}_{ij} (p_j^{\mu} - q_j^{''}).
\]

(B.4)

We split \( p \) into two parts, \( \tilde{p} \) and \( p' \), such that \( p' \) lies in the linear space generated by \( Q \) and \( \tilde{p} \) is orthogonal to \( Q \). We introduce a new set of momenta, \( k = \frac{1}{2} (p' + q') \) and \( k' = p' - q' \). Then it is easy to get

\[
P_i^{\mu} \approx -\frac{\partial}{\partial \tilde{p}_i,\mu} - \frac{\partial}{\partial k_{i,\mu}} - \hat{B}_i^{\mu} + \frac{1}{2} \sum_{j=1}^{L} \hat{A}_{ij} (p_j^{\mu} + k_j^{''}).
\]
Because \( \frac{\partial}{\partial k_{i}^{\mu}} \) commutes with \( k_{i}^{\mu} \), finally we can take \( k_{i}^{\mu} = 0 \); these two terms do not contribute, thus they can be omitted. Hence

\[
P_{i}^{\mu} \approx -\frac{\partial}{\partial p_{i,\mu}} - \tilde{B}_{i}^{\mu} + \frac{1}{2} \sum_{j=1}^{L} \tilde{A}_{ij} \tilde{p}_{j}^{\mu}.
\]

(B.6)

Appendix C: Derivation of Eq. (3.14)

We first consider the first term in Eq. (3.8b). By using Eq. (3.10) and the commutation relation Eq. (3.11b), we have

\[
\sum_{j,k} \frac{\partial A_{jk}}{\partial a_{i}} \tilde{B}_{j} \cdot \tilde{B}_{k} \approx \sum_{j,k} \frac{\partial A_{jk}}{\partial a_{i}} \tilde{B}_{j} \cdot \tilde{B}_{k} + \frac{1}{2} \sum_{j,k,a} \delta_{a a_{i}} \frac{\partial A_{jk}}{\partial a_{i}} \tilde{A}_{jk}.
\]

By virtue of the Laplace expansion of \( U \) (as the determinant of \( A \)), the second term in Eq. (3.8b) becomes

\[
D_{0} A_{0} \frac{\partial U}{\partial a_{i}} = \sum_{j,k} \frac{\partial A_{jk}}{\partial a_{i}} \tilde{A}_{jk} A_{0}.
\]

(C.2)

Substituting the above two equations into Eq. (3.8b), and multiplying both sides of the obtained equation by \( \alpha_{j,k,i} \), we get

\[
\tilde{B}_{j} \cdot \tilde{B}_{k} + \tilde{A}_{jk} \left( A_{0} + \frac{E}{2} \right) + \sum_{k} \alpha_{j,k,i} \left( D_{a_{i}} + \frac{\partial C}{\partial a_{i}} \right) \approx 0.
\]

(C.3)

Appendix D: Proof of Eq. (3.16)

We prove Eq. (3.16) by iteration. Obviously it holds when \( n = 1 \), since in this case it is just Eq. (3.14). Now suppose that this equation holds when \( n = m \). Using Eqs. (3.14) and (3.15), we get

\[
\Delta_{12}^{\mathfrak{h}_{2} \cdots \mathfrak{h}_{m}} \tilde{A}_{m+1,m+1} \equiv \Delta_{12}^{\mathfrak{h}_{2}} \tilde{A}_{13} \cdots \tilde{A}_{m+1} \tilde{A}_{11} \tilde{A}_{m+1,m+1} = \Delta_{12}^{\mathfrak{h}_{2}} \tilde{A}_{13} \cdots \tilde{A}_{m} \left( \tilde{A}_{m+1} \tilde{A}_{11} - \tilde{A}_{11} \tilde{A}_{m+1} \right) + \frac{1}{2} \Delta_{12}^{\mathfrak{h}_{2}} \tilde{A}_{13} \cdots \tilde{A}_{m} \left( \tilde{A}_{m+1} \tilde{A}_{11} - \tilde{A}_{11} \tilde{A}_{m+1} \right).
\]

(D.1)

Thus

\[
\tilde{A}_{12}^{\mathfrak{h}_{2}, \mathfrak{h}_{m}} \tilde{A}_{13} \cdots \tilde{A}_{m} \left( \tilde{A}_{m+1} \tilde{A}_{11} - \tilde{A}_{11} \tilde{A}_{m+1} \right) = \tilde{A}_{12}^{\mathfrak{h}_{2} \cdots \mathfrak{h}_{m}} \left( A_{0} + \frac{E}{2} \right).
\]

(D.2)

In the last line we have used the identity \( A_{0} + \frac{E}{2} \tilde{A}_{m+1,m+1} = \tilde{A}_{m+1,m+1} \left( A_{0} - 1 + \frac{E}{2} \right) \).
