INTRODUCTION

Vibrio vulnificus is an opportunistic marine pathogen that can cause fatal septicemic disease in both humans and eels (Gulig, Bourdage, & Starks, 2005; Morris, 1988). Human infections are generally associated with eating contaminated seafood or through open wounds that are exposed to contaminated seawater (Linkous & Oliver, 1999; Strom & Paranjpye, 2000). Fatal primary septicemia can progress rapidly, resulting in a mortality rate of >50% within days. In humans, V. vulnificus preferentially infects those who have pre-existing conditions associated with elevated iron levels, including cirrhosis, hemochromatosis, and thalassemia (Gulig et al., 2005).

Vibrio vulnificus strains are divided into three biotypes: 1, 2, and 3. Biotypes 1 and 3 are known as opportunistic pathogens in humans while the Biotype 2 is primarily an eel pathogen, and only particular isolates have been implicated in human infection (Amaro & Biosca, 1996; Bisharat et al., 1999; Efimov et al., 2013; Hor, Gao, & Wan, 1995; Tison, Nishibuchi, Greenwood, & Seidler, 1982). Although biochemically and serologically different, these three biotypes share common virulence features including iron-regulated systems.

Abstract
In gram-negative bacteria, energy-dependent active transport of iron-bound substrates across the outer membrane is achieved through the TonB systems of proteins. Three TonB systems have been identified in the human pathogen Vibrio vulnificus. The TonB1 system contains three proteins: TonB1, ExbB1, and ExbD1. Both the TonB2 and TonB3 systems have been shown to also contain a fourth protein, TtpC2 and TtpC3, respectively. Here, we report and begin to characterize two additional proteins in the TonB2 and TonB3 systems: TtpB and TtpD. Both TtpB2 and TtpD2 are absolutely required for the function of the TonB2 system in V. vulnificus. However, although both TtpB3 and TtpD3 in the TonB3 system are related to the proteins in the TonB2 system, neither are active in iron transport. All six protein components of the TonB2 system—TonB2, ExbB2, ExbD2, TtpB2, TtpC2, and TtpD2—are essential for the uptake of both endogenously produced iron-bound siderophores and exogenous siderophores produced from other organisms. Through complementation, we have shown that V. vulnificus is capable of using different TtpD2 proteins from other Vibrio species to bring in multiple siderophores. In contrast, we also demonstrate that TtpB2 must come from V. vulnificus, and not other species within the genus, to complement mutations in the TonB2 system.

KEYWORDS
Iron, TonB, TtpB, TtpD, Vibrio vulnificus
Iron is an essential element required for survival by nearly every living organism. Iron can be highly versatile, acting as both an electron donor and an electron acceptor, as well as being involved in processes ranging from cell signaling to metabolism (Crosa, 1997). Although it is extremely abundant in the Earth’s crust, iron remains very difficult for microorganisms to utilize. In aerobic conditions, iron readily forms insoluble ferric hydroxides (Crosa, Mey, & Payne, 2004). Further, microbes that colonize vertebrate animals must deal with the host’s high-affinity, iron-binding proteins including transferrin, lactoferrin, and iron-porphyrin complexes such as those found in hemoglobin (Bullen, Rogers, & Griffiths, 1978). In order to survive and cause infections within these hosts, microorganisms have evolved iron-sequestering systems. These systems are centered around siderophores—small, high-affinity iron-chelating molecules—and the cell surface receptors for these siderophores (Actis, Tolmasky, & Crosa, 1999; Crosa, 1980; Köster, Actis, Waldbeser, Tolmasky, & Crosa, 1991).

Gram-negative bacteria, such as V. vulnificus, possess an outer membrane (OM) that contains a large assortment of protein receptors. These receptors bind nutrients, minerals, and iron-bound siderophore complexes. The inner membrane (IM) is where the energy for the cell is derived. This can be in the form of adenosine triphosphate (ATP) or the proton motive force (PMF), which provides the energy needed to power the uptake of iron-bound siderophores. The periplasmic space between these two membranes presents a challenge to gram-negative bacteria. In order to breach that space, energy created by the PMF is transduced to the OM through a group of proteins known as the TonB system (Braun, 1995; Crosa et al., 2004; Postle, 2007).

The TonB system has been extensively studied in Escherichia coli, where it has been shown to contain three integral IM proteins: TonB, ExbB, and ExbD (Bassford, Bradbeer, Kadner, & Schnaitman, 1976; Bradbeer & Woodrow, 1976; Braun et al., 1996). Besides providing stabilization, both ExbB and ExbD have been shown to transduce the PMF energy to TonB, thus causing a conformational change in TonB. This new conformation allows TonB to span the periplasmic space and make contact with TonB-dependent OM receptors allowing the uptake of iron-bound siderophores (Ahmer, Thomas, Larsen, & Postle, 1995; Germon, Ray, Vianney, & Lazzaroni, 2001; Higgs, Myers, & Postle, 1998; Kuehl & Crosa, 2009; Larsen et al., 2007; Larsen, Wood, & Postle, 1993; Ollis, Manning, Held, & Postle, 2009; Postle & Larsen, 2007; Swayne & Postle, 2011). Every member of the Vibrionaceae family contains two TonB systems: the TonB1 and TonB2 systems. The TonB1 system is very similar to E. coli in that it contains three proteins: ExbB, ExbD, and TonB. The TonB2 system has previously been shown to contain a fourth protein, TtpC2 (Kuehl & Crosa, 2009, 2010; Kustusch, Kuehl, & Crosa, 2011, 2012). When grown in iron-limiting conditions, both the TonB1 and TonB2 systems have been shown to be up-regulated, while iron-rich conditions down-regulate expression (Alice, Naka, & Crosa, 2008). In addition, some Vibrio species have been shown to contain a third TonB system. The TonB3 system looks very similar to the TonB2 system in that, along with the all of the proteins found in the TonB1 system, it also has previously been shown to contain a fourth protein, TtpC3 (Kuehl & Crosa, 2009, 2010; Kustusch, Kuehl, & Crosa, 2011, 2012). Unlike the TonB1 and TonB2 systems, the TonB3 system does not appear to be regulated by iron-limiting conditions, but instead expression of this system has only been shown when the organism is grown in human serum (Alice et al., 2008).

We describe here the previously uncharacterized genes, ttpB2 and ttpD2, in the TonB2 system of V. vulnificus. The gene ttpB2 is located immediately upstream of ttpC2 and is the first gene in the tonb2 operon. In contrast, ttpD2 is the last gene in the tonb2 operon and is found downstream of tonb2. Homologs of both genes are found as part of tonb2-like systems in other Vibrio species examined. Similar uncharacterized genes, ttpB3 and ttpD3, have also been observed in the operon of the TonB3 system of V. vulnificus. Previous reports have indicated that both ttpB2 and ttpD2 are up-regulated, along with the rest of the genes within the TonB2 system, in V. vulnificus during iron-limiting conditions (Alice et al., 2008). Together, this suggests that both genes play vital roles in the TonB2-mediated iron transport of V. vulnificus.

In this study, we demonstrate that both TtpB2 and TtpD2 are essential in the TonB2 system of V. vulnificus. We demonstrate that both proteins are necessary for growth in iron-deplete conditions. In addition, we show that both TtpB2 and TtpD2 are essential for the uptake of both V. vulnificus-produced endogenous siderophores and exogenous siderophores created by other microorganisms. We have determined that the TtpB3 and TtpD3 proteins from the TonB3 system cannot complement respective mutations in the TonB2 system. Finally, we show that the TtpD2 proteins from other Vibrio species can complement a ΔttpD2 mutation and function as a part of the TonB2 system of V. vulnificus, underlying the importance and ubiquity of this protein. In contrast, TtpB2 proteins from other Vibrio species cannot complement a ttpB2 mutant.

2 | MATERIALS AND METHODS

2.1 | Bacterial strains, plasmids, and growth conditions

The bacterial strains and plasmids used in this study are listed in Table A1. V. vulnificus was routinely grown in tryptic soy broth with the addition of 10 g/liter of NaCl for a total of 1.5% NaCl (TSBS) or in minimal CM9 media (1 × M9 salts is 60 g Na2HPO4, 30 g KH2PO4, 50 g NaCl, 10 g NH4Cl per liter; pH 7.2), 0.2% casamino acids, 0.5% glucose, 10 μM CaCl2, 100 μM MgSO4; Crosa, 1980). E. coli was routinely grown in LB broth. Agar was added at 15 g/L when appropriate. Antibiotics were used at the following final concentrations: 30 μg/ml chloramphenicol (Cm) and 50 μg/ml kanamycin (Km) for E. coli, and 10 μg/ml Cm for V. vulnificus when appropriate. Thiosulfate-citrate-bile salts-sucrose agar (TCBS; Becton, Dickinson) was used as the selective medium for V. vulnificus during conjugations. For iron-limiting conditions, 2,2’-dipyridyl was added at indicated concentrations.
Iron-rich conditions were obtained by the addition of ferric ammonium citrate (FAC) at indicated concentrations.

2.2 | Sequence identity

The percent identity matrices and protein alignments were generated through Clustal Omega (Sievers et al., 2011). Protein sequences came from *V. vulnificus* CMCP6 (TtpB2 accession number WP_011081323, TtpD2 accession number AAO07317, TtpB3 accession number AAO09346, TtpD3 accession number WP_011078917), *V. vulnificus* biotype 2 ATCC 33149 (TtpB2 accession number WP_039446789, TtpD2 accession number WP_039446781), *V. cholerae* O1 Biovar El Tor (TtpB2 accession number NP_231188, TtpD2 accession number NP_231183), *V. parahaemolyticus* RIMD (TtpB2 accession number NP_799661, TtpD2 accession number NP_799666), *V. alginolyticus* 12G01 (TtpB2 accession number EAS74533, TtpD2 accession number EAS74528), and *V. anguillarum* 775 (TtpB2 accession number AEH33201, TtpD2 accession number AEH33206).

2.3 | Construction and complementation of *V. vulnificus* mutants

In-frame deletions of the entire coding sequences of genes were generated using splicing by overlap extension (SOE) PCR (Higuchi, Krummel, & Saiki, 1988; Senanayake & Brian, 1995). Upstream and downstream regions (approximately 700 bp) flanking each gene were amplified with specific primers (Table A2, Primers 1/3 and 2/4). The two 700-bp fragments with overlapping primer ends were spliced using SOE PCR with the two outside primers (Primers 1/2). The amplified fragment was cloned into the pCR2.1 vector (Invitrogen), digested with appropriate restriction enzymes, and subcloned into the suicide vector pDM4, which had been previously digested with the same restriction enzymes. *E. coli* S17-1 λpir transformed with the pDM4 (Milton, O’Toole, Horstedt, & Wolf‐Watz, 1996) derivatives was conjugated with *V. vulnificus*, and ex‐conjugants were selected on TCBS agar with 2 µg/ml Cm. For the excision of the suicide vector, clones were incubated in the absence of Cm and plated on TSA5 plates (TSBS with 1.5% agar) containing 15% sucrose. Colonies that grew on these plates were screened for Cm sensitivity, and deletions within the genes of interest were confirmed by PCR.

Complementation of deleted genes was achieved by amplifying each gene of interest by PCR with primers containing restriction sites (Table A2). The fragments were cloned into pCR2.1 vector (Invitrogen), sequenced, and then subcloned into pMMB208 (Morales, Bäckman, & Bagdasarian, 1991) under the control of the Ptac promoter. This promoter is under the control of the lacI gene harbored in the vector. The constructs were transformed into *V. vulnificus* strains by triparental conjugation with the plasmid helper pRK2013 (Figurski & Helinski, 1979). In order to induce transcription of the cloned genes, 1 mM isopropyl-β-thiogalactopyranoside (IPTG) was added to the solid and/or broth medium.

2.4 | Growth assays

Overnight cultures were diluted to an optical density at 600 nm (OD600) of 0.02 into 25 ml of either TSBS or CM9 media and incubated at 37°C while shaking at 160 rpm. Readings were taken every 30 min for 300 min. For iron-limiting conditions, 75 µM 2,2′-dipyridyl was added to CM9 media. Complementation growth assays also contained 10 µg/ml chloramphenicol and 1 mM IPTG.

2.5 | CAS assays

Overnight cultures were diluted to an optical density at 600 nm (OD600) of 0.02 into 25 ml of CM9 media and incubated at 37°C to an OD600 of 0.5 (~3 hr). Cells were normalized to an OD600 of 0.5 in 1 ml of CM9 media. Cells were then centrifuged, and 0.5 ml of supernatant was used in the chrome azurol S (CAS) assay. A ratio of 1:1 of cell supernatant to CAS solution (600 µM hexadecyltrimethylammonium bromide [HDTMA], 150 µM FeCl3, 150 µM CAS) was mixed and placed into 0.2-cm cuvettes, and the OD600 was read using a spectrophotometer at 20 min after mixing. The assay was normalized to the wild type (WT), and the final values were inverted to show a positive change for ease of reading.

2.6 | Bioassays

Bacteria were grown overnight in TSBS with the appropriate antibiotics and diluted 1/500 into TSAS containing 100 µM 2′,2′-dipyridyl. Complemented mutants also had appropriate antibiotics added as well as 1 mM IPTG. In these experiments, bacterial cells were included in the agar and, upon solidification, plates were spot inoculated with different iron sources. After incubation of the plates at 37°C for 24 hr, halos of bacterial growth surrounding the locations of the spots indicated positive results. In these experiments, ferric ammonium citrate (FAC), which does not require active transport to obtain, was included to confirm that the strain inoculated in the agar was viable. The purified compounds spotted on top of the bioassay plates to determine the functionality of the different TonB cluster of genes in *V. vulnificus* were as follows: 1 mg/ml iron-free vibriobactin (EMC Microcollections), 1 mg/ml iron-free aerobactin, 1 mg/ml iron-free enterobactin, 1 mg/ml iron-free ferrioxamine (all three from EMC Microcollections), and 500 µg/ml FAC (Sigma). Each bioassay plate was spotted with 2 µl of each indicated iron source. To test vibrioferrin, WT *V. parahaemolyticus* was streaked onto the plate. Vulnibactin and the hydroxamate siderophore, both from *V. vulnificus*, were tested by streaking either WT or the ΔvenB strain onto the bioassay plate. Halo growth around these streaks indicates that the strain within the plate can use the siderophore being produced by the streaked strain.

2.7 | RNA extractions

Wild-type *V. vulnificus* CMCP6 was grown overnight in TSBS and diluted 1/400 in CM9 with the addition of 250 µg/ml FAC for iron-rich
conditions or with the addition of 50 μM 2’2’-dipyridyl for iron-limited conditions. Cultures were grown to an optical density at 600 nm (OD_{600}) of 0.3. Samples were centrifuged, and RNA was harvested using Qiagen’s RNeasy kit with Qiagen’s RNAprotect following manufacturer’s instructions. TurboDNase (Thermofisher) was used, and manufacturer’s protocols were followed to ensure complete degradation of genomic DNA. At least three biological replicates were created for each condition.

2.8 | Semi-quantitative RT-PCR

Purified RNA samples underwent reverse transcription to synthesize cDNA using the Qiagen QuantiTect Reverse Transcription kit following manufacturer’s instructions. Control reactions without reverse transcriptase were also performed for each sample. Reverse transcriptase PCRs (RT-PCRs) were then performed using 2 μl of each reverse transcription (RT) reaction mix using gene-specific primers described in Table A2. A control without reverse transcriptase enzyme in the RT reaction mix was used for each PCR. Fragments were resolved by electrophoresis on agarose gels. At least three replicates from each biological replicate were created. Pictures of gels were taken under UV light with a Kodak Gel Logic 2200 imaging system at an exposure time of 0.1 s. Images were then analyzed using ImageJ software. Numerical values for each gene could then be normalized to our control gene glyceraldehyde 3-phosphate dehydrogenase (GAPDH) for each band.

3 | RESULTS

3.1 | *V. vulnificus* contains two novel proteins associated with the TonB2 and TonB3 systems

The bacterium *V. vulnificus* contains three TonB systems spread across its two chromosomes (Figure 1a; Kustusch et al., 2011; Tagomori, Lida, & Honda, 2002). The TonB1 system, present in all members of the Vibrionaceae, consists of three genes: *tonB1*, *exbB1*, and *exbD1*. This system is always found associated with the genes needed for heme uptake—*hutB*, *hutC*, and *hutD* (Figure 1a; Henderson & Payne, 1994; Kuehl & Crosa, 2010). The TonB1 system found in *Vibrio* is very similar to the well-studied TonB system of *E. coli*.

All bacteria in the *Vibrio* genus examined to date also contain a second TonB system, the TonB2 system. This second system has shown uptake specificity to certain iron-bound substrates in *V. vulnificus*, as well as *V. cholerae* and *V. anguillarum* (Kuehl & Crosa, 2010; Kustusch et al., 2012; Stork et al., 2007). Three proteins similar to those found in the TonB1 system—TonB2, ExbB2, and ExbD2—are found in this system. In addition, a fourth protein, *TtpC2*, has been shown to be essential for the function of the TonB2 system in multiple *Vibrio* species (Kuehl & Crosa, 2009; Kustusch et al., 2012; Stork et al., 2007). It has been alluded to, but never shown, that two additional genes may be a part of the TonB2 system (Kustusch et al., 2012). DNA sequence analysis of the *tonB2* operon, located on *V. vulnificus*’ second, larger chromosome, suggested that two open reading frames (ORFs) are present as the first and last ORFs in the *tonB2* operon. Each appears to encode for hypothetical proteins of unknown function. We have designated the first ORF in this operon as *tpbB*, and the last ORF as *tppD* for, TonB2 complex-associated transport protein B and D (Figure 1a).

The *tonB2* operon therefore appears to contain six genes, beginning with *tpbB* (Figure 1a). A detailed analysis of the nucleotide region immediately upstream of *tpbB* is shown in Figure 1b. A potential ferric uptake regulator (Fur) binding site (shown in bold) and promoter region (underlined) are clearly identified before the translational start site of *TtpB*. The *fur* sequence identified is 78.95% similar to the *fur* consensus sequence 5’-gataaggatacatc-3’ (Lavrrar & Mcintosh, 2003). Fur is a DNA-binding protein that recognizes and binds Fur binding sites. Together with Fe^{2+}, as a corepressor, this protein complex can block transcription of

\[
\text{FIGURE 1} \quad \text{The three TonB systems of *V. vulnificus* and the promoter region of the TonB2 system. (a) The TonB1, TonB2, and TonB3 systems of *V. vulnificus* are depicted with the novel genes, *tpbB* and *tppD*, noted in dark gray. (b) Nucleotide sequence analysis in the intergenic region immediately upstream of the TonB2 operon shows the putative Fur box sequence (bold) and the predicted –10 and –35 regions (underlined). The translational start site of *tpbB* is indicated by the ATG codon and the methionine (M) designation.}
\]
target genes (Troxell & Hassan, 2013). These results suggest that ttpB2 is the first gene in the tonB2 operon and suggests that the lack of iron would induce transcription of these genes.

To determine whether the TonB2 system, specifically the ttpB2 and ttpD2 genes, is transcribed at elevated levels during iron-limiting conditions, semi-quantitative reverse transcriptase (RT) PCR was performed. We saw a ~2.5-fold and ~8-fold elevated expression of ttpB2 and ttpD2, respectively, in iron-depleted conditions compared to iron-rich conditions (Figure 2). We used tonB2 expression (~3-fold increase) as a positive control. The housekeeping gene glyceraldehyde 3-phosphate dehydrogenase (GAPDH) was used for normalization. These results are very similar to what has been seen in another study (ttpB2 = ~5-fold, ttpD2 = ~8-fold, and tonB2 = ~4-fold increase) using microarray analysis (Alice et al., 2008). Together, these results clearly show that both ttpB2 and ttpD2 are induced by iron-depleted conditions and are a part of the TonB2 system.

The ttpB2 gene encodes for a hypothetical protein with a large domain of unknown function (DUF3450). This family of proteins, DUF3450, appears in both eukaryotes and bacteria and always contains about 260 amino acids (Altschul, Gish, Miller, Myers, & Lipman, 1990). This is very similar to the length of ttpB2, which encodes for 255 amino acids in V. vulnificus. The gene, ttpB2, also appears to be the first ORF in all members of the Vibrionaceae’s TonB2 systems examined. A protein alignment (Figure A1) as well as a percent identity matrix (Table 1) compares V. vulnificus to four other Vibrio species as well as a Biotype 2 isolate of V. vulnificus. The V. vulnificus strain examined in this study is a Biotype 1 isolate, and its TtpB2 protein is extremely similar to the Biotype 2’s TtpB2 (97.3%). When compared to other Vibrio species, the average similarity was about 50% (Table 1). This similarity is comparable to the rest of the known proteins in the TonB2 system (TonB2 = 45%, ExbB = 63%, ExbD = 86%, TtpC2 = 59%) when one compares V. vulnificus to these same four species (Kustusch et al., 2012). Finally, a leucine zipper motif can be found near the N-terminus in all of these homologs (Figure A1; Altschul et al., 1990). Leucine zippers are used for protein–protein interactions and are located in alpha helices where the pattern Leu-X6-Leu-X6-Leu-X6-Leu is found (Hirst, Vieth, Skolnick, & Brooks, 1996).

The ttpD2 gene encodes for a hypothetical 425 amino acid protein. It contains a number of potential tetracopeptide repeat (TPR) motifs throughout the protein (Altschul et al., 1990). TPR motifs are structural motifs present in a wide range of proteins. They generally mediate protein–protein interactions and help assemble larger multiprotein complexes (Schultz, Milpetz, Bork, & Ponting, 1998). As with ttpB2, ttpD2 also appears in all members of the Vibrionaceae examined. A protein alignment (Figure A2) and a percent identity matrix (Table 2) compares V. vulnificus to four other Vibrio species as well as a Biotype 2 isolate of V. vulnificus. Overall, TtpD2 had a much lower similarity (35%) to other Vibrio species as compared to TtpB2 or any of the other four proteins in the TonB2 system (Table 2; Kustusch et al., 2012). As with TtpB2, TtpD2 also had a very high similarity (95.5%) to the TtpD2 protein in the V. vulnificus Biotype 2 strain (Table 2). Unlike TtpB2, where large stretches of similarity were observed (Figure A1), TtpD2 had only very short stretches of homology between the different TtpD2 proteins found in the other four Vibrio species (Figure A2).

A third TonB3 system has been identified in V. vulnificus as well as in a number of Vibrio species and species within the genera Alivibrio, Photobacterium, and Teredinibacter (Kustusch et al., 2011). This system appears to contain the six proteins found in the TonB2 system (Figure 1a). In contrast to the TonB2 system, a gene encoding an outer membrane (OM) receptor protein can be found at the beginning of the tonB3 operon. TtpB2 and TtpD2 were compared to their counterparts in the TonB3 system. Only a 30.3% similarity was found between the TtpB2 and TtpD3 proteins and a 23% similarity between TtpB2 and TtpD3 (Tables 1 and 2). This is very similar to homologies in other known TonB2 system proteins when comparing V. vulnificus’ TonB2 system against its TonB3 system: TonB 27%, ExbB 40%, ExbD 57%, and TtpC 37% (Kustusch et al., 2012).

3.2 | Both TtpB2 and TtpD2 are necessary components of the TonB2 system in mediating growth and the transport of endogenous siderophores

Growth assays were used to determine the necessity and essentiality of TtpB2 and TtpD2 in the TonB2 system. An assortment of
Protein sequences of TtpB2 were compared against: *V. vulnificus* VSSD100 (V. vulnificus *V. cholerae* CA401 (V. cho); *V. anguillarum* 775 (V. ang); *V. alginolyticus* 12G01 (V. alg); and *V. parahaemolyticus* RIMD (V. para). The TtpB3 protein from *V. vulnificus* CMCP6 (V. vuln B3 System) is also compared.

### TABLE 1  Percent identity matrix of TtpB2 using different Vibrio species

| TtpB2   | V. vul (%) | V. vul Biotype 2 (%) | V. cho (%) | V. ang (%) | V. alg (%) | V. para (%) | V. vul TonB3 System (%) |
|---------|------------|----------------------|------------|------------|------------|-------------|-------------------------|
| V. vul  | 100        |                      |            |            |            |             |                         |

Note: Percent identity matrices generated using ClustalO (Sievers et al., 2011) are shown using TtpD2. Protein sequences of TtpD2 were compared against: *V. vulnificus* CMCP6 (V. vul); *V. vulnificus* VSSD100 (V. vul Biotype 2); *V. cholerae* CA401 (V. cho); *V. anguillarum* 775 (V. ang); *V. alginolyticus* 12G01 (V. alg); and *V. parahaemolyticus* RIMD (V. para). The TtpD3 protein from *V. vulnificus* CMCP6 (V. vul TonB3 System) is also compared.

Data demonstrate the essentiality of TtpB2 and TtpD2 in the TonB2 system for growth in iron-depleted conditions. Bioassays were used to investigate the essentiality of TtpB2 and TtpD2 within the TonB2 system for the uptake of endogenous siderophores. *V. vulnificus* can produce two siderophores, vulnibacillin, and the uncharacterized hydroxamate siderophore (Simpson & Oliver, 1983). An assortment of mutants was tested with various combinations of deletions in different TonB systems (Table 3). We have previously tested the role of TtpC2 in the TonB2 system, but not TtpB2 nor TtpD2 (Kustusch et al., 2012). It was previously shown that both the TonB1 and TonB2 systems, but not the TonB3 system, could transport both of the endogenous siderophores of *V. vulnificus* (Kustusch et al., 2012). As shown in Table 3, WT, as well as any single mutant, could transport both native siderophores. Similar to the trend in the growth assay, any double mutant tested that left both the TonB1 and TonB2 systems missing a component of their respective system could not uptake endogenous siderophores. This was true when tonB2, ttpB2, or ttpD2 was deleted in conjunction with a ΔtonB1 mutant (Table 3). These results indicate that both TtpB2 and TtpD2 are necessary components of the TonB2 system when transporting endogenous siderophores. In
addition, these data demonstrate that TtpB3 and TtpD3 cannot be used in place of TtpB2 or TtpD2, respectively, because both TtpB3 and TtpD3 were still available in these strains. Both of these siderophores were also unable to be used when all three TonB systems were deleted using a ΔtonB1 ΔtonB2 ΔtonB3 strain, ΔtonB1 ΔttpB2 ΔtonB3 strain, or a ΔtonB1 ΔttpD2 ΔtonB3 strain (Table 3). To determine that the deletions did not have any polar effects and that the mutations were truly in the targeted genes, assorted complemented strains were also utilized in this assay. Endogenous siderophores could once again be brought into the cell when either the TonB1 system was complemented (w/ptonB1), or the TonB2 system was complemented (w/pttpB2 in a ttpB2 deletion or w/pttpD2 in a ttpD2 deletion), further confirming the importance of these proteins to the uptake of endogenous siderophores and the ability to use either (Table 3).

We further analyzed these mutants through the use of chrome azurol S (CAS) assays. Briefly, these colorimetric assays can be used to detect secreted iron-bound complexes, like siderophores. When in iron-depleted conditions, siderophores are secreted from *V. vulnificus* into the surrounding media. If the strain has a functional TonB system that can mediate the uptake of these now iron-bound siderophores, they will be brought back into the cell. If the TonB systems are nonfunctional and the iron-bound siderophores cannot be brought back into the cell, an accumulation builds up in the medium. By harvesting the supernatant of different TonB mutants and mixing it with CAS reagents, one can determine which strain is capable of siderophore uptake through a color change.

The results from these experiments can be seen in Figure 4. Confirming our bioassay results, both the TonB1 and TonB2 systems are used for the uptake of endogenous siderophores. Both single and double mutations that still allow either the TonB1 or the TonB2 system to function show the same amount of siderophore production as the wild-type strain. Only when genes in both the TonB1 and TonB2 systems are deleted do we see an increase in relative production of endogenous siderophores. We see the same results in the double mutants when tonB1 is deleted along with either tonB2, ttpB2, or ttpD2. This important result confirms the essentiality of both TtpB2 and TtpD2 in the TonB2 system.

It has previously been shown that vulnibactin, produced through an assortment of genes including venB, is the primary siderophore secreted under iron-deplete conditions (Kustusch et al., 2012). In Figure 4, we see approximately the same levels of vulnibactin in the wild-type strain compared to the ΔvenB strain and the triple mutants in conjunction with ΔvenB. This is due to the wild-type strain bringing vulnibactin into the cell, leaving very little in the supernatant, and the mutant strain never producing vulnibactin to begin with. These results further show that the iron-binding molecule that was both present in the supernatant of the double and triple mutants and caused an increase in values was indeed vulnibactin and not an artifact or the hydroxamate-type siderophore.

### 3.3 Both TtpB2 and TtpD2 are essential for the TonB2 system in mediating the transport of exogenous siderophores

*Vibrio vulnificus* can thrive in a variety of environments and hosts, because of the evolved ability to use a diverse assortment of iron sources. These include the use of exogenous siderophores, that is, siderophores that are produced by other bacterial and fungal species (Alice et al., 2008; Aso, Miyoshi, Nakao, Okamoto, & Yamamoto, 2002). In order to evaluate any potential roles for TtpB2 and TtpD2 in the uptake of these exogenous siderophores by *V. vulnificus*, we performed bioassays with an assortment of
TABLE 3 TtpB2 and TtpD2 are essential components of the TonB2 system mediating the uptake of endogenous siderophores in V. vulnificus

| V. vulnificus strain or genotype | Growth on indicated iron sources\(^a\) | FAC | Vulnibactin | Hydroxamate |

| ΔtonB1 ΔtpB2 ΔtonB3 w/ptonB1 w/pttB2(Vvul) | + | – | – |
| ΔtonB1 ΔtpB2 ΔtonB3 w/ptonB1 w/pttB2(Vvul) | + | – | – |

\(^a\)Growth was determined by the presence of halos (+) or lack thereof (−) around each iron source indicated after 18 hr at 37°C. FAC was added as a positive control, as it does not require active transport and confirmed our imbedded strain was viable in each plate. Two microliters of FAC was spotted (500 µg/ml). Wild-type V. vulnificus was streaked on the plate as a source of vulnibactin (the dominant siderophores produced), and the halo of growth was monitored around the streak. The V. vulnificus ΔvenB mutant strain is deficient in the production of vulnibactin and was streaked onto the plate to access the use of the hydroxamate siderophore by each strain.

\(^b\)The triple mutant strain ΔtonB1 ΔtonB2 ΔtonB3 contained an additional mutation in the lacZ gene (Strain AA-12 in Table A1). This mutation was necessary for previous studies and has been shown to not affect Fe-siderophore transport (Alice et al., 2008).

Each of the exogenous siderophores V. cholerae vibriobactin, V. parahaemolyticus vibrio ferrin, Streptomyces species ferrioxamine, and E. coli enterobactin was able to be brought into the cell by using either the TonB1 or the TonB2 system. Single mutants affecting any of the TonB systems were able to utilize these exogenous siderophores. It is only when a ΔtonB1 mutation is in conjunction with a TonB2 system mutation (ΔtonB2, ΔtpB2, or ΔtpD2) or when a triple mutant, missing components of all three TonB systems, is used that the siderophores cannot be brought into the cell. These results provide additional evidence that both TtpB2 and TtpD2 are necessary components of the TonB2 system and must be functional for V. vulnificus to utilize exogenous siderophores.

Quadruple mutants, where vulnibactin production is halted due to the deletion of venB, were also unable to utilize exogenous siderophores listed above. Complementation of these quadruple mutants with either tonB1, ttpB2, or ttpD2 restored the uptake of all of the above exogenous siderophores (Table 4). These quadruple strains were important to assay because they prove that vulnibactin is unable to steal the iron that is bound by the exogenous siderophore and that the exogenous siderophores are indeed the source of iron in this study. These results again demonstrate the essentiality of TtpB2 and TtpD2 in the TonB2 system.

In contrast, it has been shown that aerobactin, a commonly produced siderophore by enterobacteria, can only be brought in through the TonB2 system (Kustusch et al., 2012; de Lorenzo & Martinez, 1988). Consistent with these findings, double and triple mutants behaved as would be anticipated in a similar fashion to single mutants in the TonB2 system preventing aerobactin from being utilized (Table 4).

3.4 Complementation of a V. vulnificus ΔtpB2 mutant must come from V. vulnificus, while a ΔtpD2 mutant can be complemented by different members of the Vibrionaceae

It has previously been demonstrated that the TtpC2 protein from different Vibrio species can be substituted for a ΔtpC2 mutation in V. vulnificus to restore function of the TonB2 system (Kustusch et al., 2012). To better examine the importance and conservation of function of both TtpB2 and TtpD2, proteins from other Vibrio species were substituted into a V. vulnificus triple mutant (ΔtonB1 ΔtpB2 ΔtonB3 or ΔtonB1 ΔtpD2 ΔtonB3). Complementing plasmids were moved into appropriate strains, and growth assays were performed.

Consistent with the past findings related to ΔtpC2, the ΔtonB1 ΔtpD2 ΔtonB3 mutant growth was complemented using the majority of other Vibrio species’ homologous genes (Figure 5a). All TtpD2 proteins from the six Vibrio species tested were able to restore growth. Growth in these conditions was not restored to the strains with nonfunctional TonB2 systems, when TtpD3 from the TonB3 system was used for complementation, demonstrating a distinction in roles for TtpD2 and TtpD3.

In contrast to these TtpD2 findings and previous findings with TtpC2, growth was only restored in a TtpB2 mutant when a complementing
plasmid restoring TonB1 or a TtpB2 protein from a *V. vulnificus* species (wild-type or a Biotype 2 strain) was utilized. Results using the ΔtonB1 ΔtpbB2 ΔtonB3 strains can be seen in Figure 5b. Provision of any other TtpB2 protein from different *Vibrio* species or TonB3 was not able to restore growth. These results demonstrate that the TonB2 system has a specificity for its own TtpB2 protein but not TtpD2.

In addition to determining if growth could be restored through complementation with homologous copies of TtpB2 and TtpD2, bioassays were used to examine restoration of the ability to utilize siderophores. As would be expected, bioassays utilizing homologous TtpB2 from other *Vibrio* species or TonB3 was not able to restore siderophore utilization. These results demonstrate that the TonB2 system has a specificity for its own TtpB2 protein but not TtpD2.

4 | DISCUSSION

*Vibrio vulnificus* is a gram-negative opportunistic pathogen that can infect humans as well as eels (Gulig et al., 2005; Hor, Chang, Chang, Lei, & Ou, 2000). In humans, fatal septicemia is often associated with large amounts of iron found in a person's blood due to several chronic or acute conditions (Wright & Morris, 1991). This high concentration of iron is a major risk factor for many bacterial infections, including *V. vulnificus* (Crosa et al., 2004). Siderophores are small molecular chelators of iron that many microbes secrete in order to sequester iron from their environment (Neilands, 1995). *V. vulnificus* produces two such siderophores, the dominate siderophore, vulnibactin, and a hydroxamate-type compound (Okujo et al., 1994; Simpson & Oliver, 1983). Once bound to iron, these siderophores first interact with an OM receptor before being internalized. Energy, produced through the PMF in the IM, must be transduced to the OM to allow iron-bound siderophores into the periplasm, and consequently into the cytosol of the cell. The TonB systems are responsible for harnessing this energy and transferring it to the OM receptor (Braun, 1995; Crosa et al., 2004; Postle & Larsen, 2007). Unlike the well-studied, single TonB system of *E. coli*, *V. vulnificus* contains three TonB systems (Kustusch et al., 2011). Previous in silico work identified the potential genes in *V. vulnificus* three TonB systems. While the TonB1 system has the same three genes (*tonB1, exbB1*, and *exbD1*) as *E. coli*, the TonB2 and TonB3 systems of *V. vulnificus* appeared to have an additional gene, *tpbC*, as well as two ORFs found at the beginning and end of each operon (Kustusch et al., 2012). In this study, we have demonstrated that these two ORFs, now renamed *tpbB2* and *tpdD2*, are essential and necessary for the TonB2 system. We have identified a potential Fur binding site and promoter region upstream of *tpbB2* consistent with previous studies that have
alluded to the presence of a Fur binding site through gel shift analysis using a His-tagged Fur protein (Alice et al., 2008). In addition, our semi-quantitative RT-PCR analysis has shown the same, if not greater, up-regulation of \( \text{ttpB2} \) and \( \text{ttpD2} \) in iron-deplete versus iron-rich conditions as compared to \( \text{tonB2} \). This up-regulation has also been demonstrated through microarray analysis yielding similar fold expression as well as promoter fusion assays (Alice et al., 2008). While present in the TonB3 system, we have shown that \( \text{ttpB3} \) and \( \text{ttpD3} \) cannot substitute for their apparent homologs in the TonB2 system. While the orientation and arrangement of the \( \text{tonB2} \) and \( \text{tonB3} \) operons appear similar, they in fact are very different from each other. Every member of the Vibrionaceae contains the \( \text{TonB1} \) and \( \text{TonB2} \) systems, while only a limited few contain the \( \text{TonB3} \) system (Kustusch et al., 2011). Overall, the \( \text{TonB2} \) and \( \text{TonB3} \) systems are only about 35% similar on the amino acid level, with \( \text{TtpB2-B3} \) and \( \text{TtpD2-D3} \) having 30% and 23% homology, respectively. While multiple studies have shown that both the \( \text{TonB1} \) and \( \text{TonB2} \) systems transport iron-bound siderophores, other studies have shown that the \( \text{TonB3} \) system does not appear to transport any iron-related product under iron-limiting conditions (Alice et al., 2008; Kuehl & Crosa, 2009; Kustusch et al., 2012). It appears that the \( \text{TonB3} \) system is only transcriptionally activated when grown in human serum or grown in minimal media with glycerol as a sole carbon source with low concentrations of casamino acids (Alice & Crosa, 2012; Alice et al., 2008).

In this study, the essentiality of both \( \text{TtpB2} \) and \( \text{TtpD2} \) for iron transport was evaluated using growth assays, bioassays, and CAS

---

*The embedded strain, VSRK615 (ΔtonB1 ΔtttB2 ΔtonB3 ΔvenB), contained the complementing plasmid pMMB208 expressing TtpB2 from the various *Vibrio* species listed at the top of the table.*

*Growth was determined by the presence of halos (+) or lack thereof (−) around each iron source indicated after 18 hr at 37°C. Two microliters of each iron source was spotted on the surface of the plates in the following concentrations: FAC, 500 µg/ml; vibriobactin, 1.0 mg/ml; ferrioxamine, 1.0 mg/ml; enterobactin, 1.0 mg/ml; and aerobactin, 1.0 mg/ml. Wild-type *V. vulnificus* and *V. parahaemolyticus* were streaked on the plate as a source of vulnibactin and vibrioferrin, respectively, and the halo of growth was monitored around the streak. A *V. vulnificus* ΔvenB mutant was streaked onto the plate to test for growth around the hydroxamate siderophore.*
V. baThe embedded strain VSRK643 (ΔtonB1 ΔtpdB ΔtonB3 ΔvenB) contained the complementing plasmid pMMB208 expressing TtpD2 from the various Vibrio species listed at the top of the table. Growth was determined by the presence of halos (+) or lack thereof (−) around each iron source indicated after 18 hr at 37°C. Two microliters of each iron source was spotted on the surface of the plates in the following concentrations: FAC, 500 µg/ml; vibriobactin, 1.0 mg/ml; ferrioxamine −, 1.0 mg/ml; enterobactin, 1.0 mg/ml; and aerobactin, 1.0 mg/ml. Wild-type V. vulnificus and V. parahaemolyticus were streaked on the plate as a source of vulnibactin and vibrioferrin, respectively, and the halo of growth was monitored around the streak. A V. vulnificus ΔvenB mutant was streaked onto the plate to test for growth around the hydroxamate siderophore.

Our results clearly demonstrate that both proteins are necessary components of the TonB2 system and are required for that system to function. This study has also demonstrated that either the TonB1 or the TonB2 system, with all six proteins present, must be functional for the iron uptake necessary for robust growth in iron-limited conditions. In contrast, these systems do not need to be present for growth in iron-rich conditions where freely available iron is readily available. In addition, our CAS assays and bioassays have shown that TtpB2 and TtpB2 are essential for the uptake of both endogenous and exogenous siderophores through the TonB2 system. While most exogenous siderophores could be brought in through the TonB1 or TonB2 system, aerobactin is only brought in by the TonB2 system. Finally, this study has shown that TtpB3 and TtpD3 cannot complement the TonB2 system deletions for growth, in both their natively expressed levels or when artificially overexpressed, in the iron-limited conditions tested in this study or for the uptake of siderophores.

TtpB2 and TtpD2 are predicted to be 255 and 425 amino acids, respectively. TtpB2 contains a leucine zipper motif (Leu-X6-Leu-X6-Leu-X6-Leu) toward the N-terminus, while TtpD2 contains a number of TPR motifs. Both of these conserved motifs suggest that TtpB2 and TtpD2 function as part of multiprotein complexes or through protein–protein interactions (Hirst et al., 1996; Schultz et al., 1998). Current work is underway to examine these motifs and the way in which these proteins interact within the TonB2 system.

Our RT-PCR analysis shows a ~2.5-fold increase in the expression of ttpB2 and an 8-fold increase in the expression of ttpD2 confirming an up-regulation of these genes alongside tonB2 in iron-depleted conditions relative to iron-rich.

Previously, both TonB2 and TtpC2 have been shown to be interchangeable among Vibrio species to create a functional TonB2 system (Kustusch et al., 2012; Stork et al., 2007). Similarly to other genes in the TonB2 system examined thus far, we demonstrate that V. vulnificus TtpD2 function can be complemented with homologs from other Vibrio species despite only around 35% amino acid conservation. Surprisingly however, V. vulnificus TtpB2, despite having a higher level of conservation (around 50%), cannot be complemented with the homolog from other species. Only the Biotype 2 strain with 97% homology to our previous studies have shown the importance of V. vulnificus TonB systems and its contribution to growth and virulence (Alice et al., 2008; Kustusch et al., 2012). Here, we demonstrate that two additional proteins, TtpB2 and TtpD2, are essential elements for a functional TonB2 system. In conclusion, TtpB2 and TtpD2 are required for V. vulnificus growth and the uptake of endogenous and exogenous siderophores in iron-limited conditions similar to those the organism experiences within a host. Both the specificity of TtpB2 and the ubiquitous nature of TtpD2 will be further analyzed in future studies.

**ACKNOWLEDGMENTS**

We would like to thank the University of Portland, which provided research space and funds to R.J.K., and summer stipend money to all authors. This work was supported by grants 2014204 and NS-2017310 from The M.J. Murdock Charitable Trust to R.J.K.

**CONFLICT OF INTEREST**

The authors have no conflicts of interest to disclose.

### Plasmids

| Plasmid           | Description                                                                 | Reference or source |
|-------------------|-----------------------------------------------------------------------------|---------------------|
| pPCR2.1           | TA cloning vector; Amp’, Km’                                                | Invitrogen          |
| pDM4              | Suicide vector with oriR6K; Cm’ sacB                                        | Milton et al. (1996) |
| pRK2013           | Helper plasmid; Km’                                                         | Figurski and Helinski (1979) |
| pMMB208           | Broad-host-range expression vector; Cm’ P tac                                | Morales et al. (1991) |
| ptonB1            | *V. vulnificus* CMCP6 tonB1 cloned into pMMB208                              | Alice et al. (2008) |
| ptonB2            | *V. vulnificus* CMCP6 tonB2 cloned into pMMB208                              | Alice et al. (2008) |
| ptonB3            | *V. vulnificus* CMCP6 tonB3 cloned into pMMB208                              | Alice et al. (2008) |
| ptpB2(Vvul)       | *V. vulnificus* CMCP6 ttpB2 cloned into pMMB208                              | This study          |
| ptpB2(Vcho)       | *V. cholerae* CA401 ttpB2 cloned into pMMB208                                | This study          |
| ptpB2(Vpara)      | *V. parahaemolyticus* RIMD ttpB2 cloned into pMMB208                         | This study          |
| ptpB2(Valg)       | *V. alginoleticus* 12G01 ttpB2 cloned into pMMB208                           | This study          |
| ptpB2(Vang)       | *V. anguillarum* 775 ttpB2 cloned into pMMB208                               | This study          |
| ptpD2(Vvul)       | *V. vulnificus* CMCP6 ttpD2 cloned into pMMB208                              | This study          |
| ptpD2(Vcho)       | *V. cholerae* CA401 ttpD2 cloned into pMMB208                                | This study          |
| ptpD2(Vpara)      | *V. parahaemolyticus* RIMD ttpD2 cloned into pMMB208                         | This study          |
| ptpD2(Valg)       | *V. alginoleticus* 12G01 ttpD2 cloned into pMMB208                           | This study          |
| ptpD2(Vang)       | *V. anguillarum* 775 ttpD2 cloned into pMMB208                               | This study          |
| ptpB3(Vvul TonB3) | *V. vulnificus* CMCP6 ttpB3 from the TonB3 system cloned into pMMB208       | This study          |
| ptpD3(Vvul TonB3) | *V. vulnificus* CMCP6 ttpD3 from the TonB3 system cloned into pMMB208       | This study          |
| ptpB2(Vvul Biotype 2) | *V. vulnificus* biotype 2 ATCC 33149 ttpB2 cloned into pMMB208               | This study          |
| ptpD2(Vvul Biotype 2) | *V. vulnificus* biotype 2 ATCC 33149 ttpD2 cloned into pMMB208              | This study          |

Abbreviations: Amp’, ampicillin resistant; Cm’, chloramphenicol resistant; Km’, kanamycin resistant; Sm’, streptomycin resistant; Tp’, trimethoprim resistant.
### TABLE A2 Primers used in this study

| Name            | Sequence 5’-3’
|-----------------|-----------------|
| **SOE PCR**     |                 |
| TTPB2-1         | CGAACTAGTCGCTGCAAAGCGATCGGCAAG |
| TTPB2-2         | CGAACCggggGTAACAAGTGTTGCTGCTC |
| TTPB2-3         | ATACGGGGCCAGTAAGGCGCGGATGTTGAAATG |
| TTPB2-4         | CATATTCAACATCCCGGGGGGCTTTCATGCGCCGATGTTG |
| TTPD2-1         | CGAACTAGTCAGCAGCACGCAACTCGGTTC |
| TTPD2-2         | CGACCCGGGGCCATGGCGTTGCTCGTCAAT |
| TTPD2-3         | ATATGCGCTGGGATGCGCAATGCGATGGCTGCGACAAA |
| TTPD2-4         | TTTGTCGGGCAGCAATTGCTGGAGCGGAGGCAATTG |
| **Complementation** |                 |
| TTPB2_Vvul_For  | Cgacgtcagcaacagcttggaagatggcaa |
| TTPB2_Vvul_Rev  | Cgagatctcctgtttggtttctgctgctg |
| TTPB2_Vcho_For  | Cgagatccctctttacccgggaatagacg |
| TTPB2_Vcho_Rev  | Cgacccgggacgagccttttctgctgctg |
| TTPB2_Vpara_For | Cgacgtcagttggaagagcggcaactaca |
| TTPB2_Vpara_Rev | Cgacgtcagttggaagagcggcaactaca |
| TTPB2_Vang_For  | Cgacgtcagttggaagagcggcaactaca |
| TTPB2_Vang_Rev  | Cgacgtcagttggaagagcggcaactaca |
| TTPD2_Vvul_For  | Cgacgtcagttggaagagcggcaactaca |
| TTPD2_Vvul_Rev  | Cgacgtcagttggaagagcggcaactaca |
| TTPD2_Vcho_For  | Cgacgtcagttggaagagcggcaactaca |
| TTPD2_Vcho_Rev  | Cgacgtcagttggaagagcggcaactaca |
| TTPD2_Vpara_For | Cgacgtcagttggaagagcggcaactaca |
| TTPD2_Vpara_Rev | Cgacgtcagttggaagagcggcaactaca |
| TTPD2_Vang_For  | Cgacgtcagttggaagagcggcaactaca |
| TTPD2_Vang_Rev  | Cgacgtcagttggaagagcggcaactaca |
| **Semi-Quantitative RT-PCR** |                 |
| TTPB2_RT_For    | CTTGCTGCGTAATCCCAGTC |
| TTPB2_RT_Rev    | CATCAATCAACAGACATGCGAT |
| TTPD2_RT_For    | AACTGCGCTGAAGCTGACTG |
| TTPD2_RT_Rev    | TGCAACAACGGGCTGCAACTT |
| TONB2_RT_For    | CGTGGAAACACTACGCTG |
| TONB2_RT_Rev    | CGTGGAAACACTACGCTG |
| 16srRNA_RT_For  | GACTTCAACCCAGCTGAAC |
| 16srRNA_RT_Rev  | CAGATGGCGACGTGAAATCA |
| GAPDH_RT_For    | TTAGTGGCAGAATGGAGT |
| GAPDH_RT_Rev    | TGGTTCAATCAGTGCGGCAATG |

*aUnderlined portion represents restriction enzyme recognition sites.*
FIGURE A1  Sequence alignments of TtpB2 and their homologs. A ClustalO (Sievers et al., 2011) sequence alignment was performed using TtpB2 from: V. vulnificus CMCP6 (Vvul TtpB2); V. vulnificus VSSD100 Biotype 2 (Vvul Biotype 2 TtpB2); V. anguillarum 775 (Vang TtpB2); V. alginolyticus 12G01 (Valg TtpB2); V. parahaemolyticus RIMD (Vpara TtpB2); and V. cholerae CA401 (Vcho TtpB2). Numbering refers to the amino acid position in the primary sequence of the respective proteins. Conserved residues are marked with an asterisk (*), similar residues are annotated by a period (.), and a colon (:) indicates conservation between groups of strongly similar properties. The leucine zipper motif is highlighted in gray with the leucine (L) residues bolded.
**FIGURE A2** Sequence alignments of TtpD2 and their homologs. A ClustalO (Sievers et al., 2011) sequence alignment was performed using TtpD2 from: *V. vulnificus* CMCP6 (*Vvul* TtpD2); *V. vulnificus* VSSD100 Biotype 2 (*Vvul* Biotype 2 TtpD2); *V. anguillarum* 775 (*Vang* TtpD2); *V. cholerae* CA401 (*Vcho* TtpD2); *V. alginolyticus* 12G01 (*Valg* TtpD2); and *V. parahaemolyticus* RIMD (*Vpara* TtpD2). Numbering refers to the amino acid position in the primary sequence of the respective proteins. Conserved residues are marked with an asterisk (*), similar residues are annotated by a period (.), and a colon (:) indicates conservation between groups of strongly similar properties.
