WORKSHOP ON THE HOMOTOPY THEORY OF HOMOTOPY THEORIES

JULIA E. BERGNER

ABSTRACT. These notes are from a series of lectures given at the Workshop on the Homotopy Theory of Homotopy Theories which took place in Caesarea, Israel, in May 2010. The workshop was organized by David Blanc, Emmanuel Farjoun, and David Kazhdan, and talks not indicated otherwise were given by the author.

1. OVERVIEW: INTRODUCTION TO THE HOMOTOPY THEORY OF HOMOTOPY THEORIES

To understand homotopy theories, and then the homotopy theory of them, we first need an understanding of what a “homotopy theory” is. The starting point is the classical homotopy theory of topological spaces. In this setting, we consider topological spaces up to homotopy equivalence, or up to weak homotopy equivalence. Techniques were developed for defining a nice homotopy category of spaces, in which we define morphisms between spaces to be homotopy classes of maps between CW complex replacements of the original spaces being considered.

However, the general framework here is not unique to topology; an analogous situation can be found in homological algebra. We can take projective replacements of chain complexes, then chain homotopy classes of maps, to define the derived category, the algebraic analogue of the homotopy category of spaces.

The question of when we can make this kind of construction (replacing by some particularly nice kinds of objects and then taking homotopy classes of maps) led to the definition of a model category by Quillen in the 1960s [61]. The essential information consists of some category of mathematical objects, together with some choice of which maps are to be considered weak equivalences. The additional information, and the axioms this data must satisfy, guarantee the existence of a well-behaved homotopy category as we have in the above examples, with no set theory problems arising.

A more general notion of homotopy theory was developed by Dwyer and Kan in the 1980s. Their simplicial localization [36] and hammock localization [35] techniques provided a method in which a category with weak equivalences can be assigned to a simplicial category. More remarkably, they showed that up to a natural notion of equivalence (now called Dwyer-Kan equivalence), every simplicial category arises in this way [34]. Thus, if a “homotopy theory” is just a category with weak equivalences, then we can just as easily think of simplicial categories as homotopy theories. In other words, simplicial categories provide a model for homotopy theories.

Date: April 28, 2013.
The author was partially supported by NSF grant DMS-0805951.
However, with Dwyer-Kan equivalences, the category of (small) simplicial categories itself forms a category with weak equivalences, and is therefore a homotopy theory. Hence, we have a “homotopy theory of homotopy theories,” the topic of this workshop. In fact, this category was shown to have a model structure in 2004, making it a homotopy theory in the more rigorous sense [20]. (In more recent work, Barwick and Kan have given “categories with weak equivalences” a model structure which is equivalent to this one [4].)

In practice, unfortunately, this model structure is not as nice as a homotopy theorist might wish. It is not compatible with the monoidal structure on the category of simplicial categories, does not seem to have the structure of a simplicial model category in any natural way, and has weak equivalences which are difficult to identify for any given example. Therefore, a good homotopy theorist might seek an equivalent model structure with better properties.

An alternate model, that of complete Segal spaces, was proposed by Rezk in 2000, in fact before the model structure on simplicial categories was established [64]. Complete Segal spaces are just simplicial diagrams of simplicial sets, satisfying some conditions which allow them to be thought of as something like simplicial categories but with weak composition. Their corresponding model category is cartesian closed, and is in fact given by a localization of the Reedy model structure on simplicial spaces [62]. Hence, the weak equivalences between fibrant objects are just levelwise weak equivalences of simplicial sets.

Meanwhile, in the world of category theory, simplicial categories were seen as models for (∞, 1)-categories. These particular examples of ∞-categories, with k-morphisms defined for all k ≥ 1, satisfy the property that for k > 1, the k-morphisms are all weakly invertible. To see why simplicial categories were a natural model, it is perhaps easier to consider instead topological categories, where we have a topological space of morphisms between any two objects. The 1-morphisms are just points in these mapping spaces. The 2-morphisms are paths between these points; at least up to homotopy, they are invertible. Then 3-morphisms are homotopies between paths, 4-morphisms are homotopies between homotopies, and one could continue indefinitely.

In the 1990s, Segal categories were developed as a weakened version of simplicial categories. They are simplicial spaces with discrete 0-space, and look like homotopy versions of the nerves of simplicial categories. They were first defined by Dwyer-Kan-Smith [37], but developed from this categorical perspective by Hirschowitz and Simpson [43]. The model structure for Segal categories, begun in their work, was given explicitly by Pelissier [58].

Yet another model for (∞, 1)-categories was given in the form of quasi-categories or weak Kan complexes, first defined by Boardman and Vogt [27]. They were developed extensively by Joyal, who defined many standard categorical notions, for example limits and colimits, within this more general setting [45], [47]. The notion was adopted by Lurie, who established many of Joyal’s results independently [53].

Comparisons between all these various models were conjectured by several people, including Toën [70] and Rezk [64]. In fact, Toën proved that any model category satisfying a particular list of axioms must be Quillen equivalent to the complete Segal space model structure, hence axiomatizing what it meant to be a homotopy theory of homotopy theories, or homotopy theory of (∞, 1)-categories [71].
Eventually, explicit comparisons were made, as shown in the following diagram:

\[
\begin{array}{cccccc}
S\mathcal{C} & \xleftarrow{\alpha} & \text{SeCat}_f & \xrightarrow{\beta} & \text{SeCat}_c & \xrightarrow{\gamma} \text{CSS} \\
Q\mathcal{C} & \downarrow & & & & \\
\end{array}
\]

The single arrows indicate that Quillen equivalences were given in both directions, and these were established by Joyal and Tierney \cite{48}. The Quillen equivalence between simplicial categories and quasi-categories was proved in different ways by Joyal \cite{47}, Lurie \cite{53}, and Dugger-Spivak \cite{32}, \cite{33}. The zig-zag across the top row was established by the author \cite{24}. It should be noted that the additional model structure \text{SeCat}_f for Segal categories was established for the purposes of this proof; the original one is denoted \text{SeCat}_c.

At this point, one might ask what these ideas are good for. Are they just a nice way of expressing abstract ideas, or do they help us to understand specific mathematical situations? The answer is that they are being used in a multitude of areas. We list several here, but do not claim that this list is exhaustive.

1. **Algebraic geometry**
   Many of the models are being used for various purposes in algebraic geometry. Authors such as Simpson, Toën, and Vezzosi are using Segal categories \cite{43}, \cite{72}. Lurie is using quasi-categories \cite{50}, \cite{51}, and Barwick is using complete Segal spaces and quasi-categories \cite{3}.

2. **K-theory**
   Simplicial categories are used frequently in this area; we mention Blumberg-Mandell \cite{26} and Toën-Vezzosi \cite{73}; the latter mention ways to generalize their work to Segal categories as well.

3. **Representation theory**
   Quasi-categories are being used, for example by Ben-Zvi, Francis, and Nadler \cite{10}, \cite{11}, \cite{12}, \cite{13}, \cite{14}. The author has done some work using complete Segal spaces \cite{18}.

4. **Deformation theory**
   Lurie is using quasi-categories \cite{52}, and Pridham has developed an application of complete Segal spaces \cite{60}.

5. **Homotopy theory**
   Lurie has used quasi-categories to prove results in stable homotopy theory \cite{56}, and other models for Goodwillie calculus \cite{54}.

6. **Topological field theories**
   Lurie has used complete Segal spaces to prove the Cobordism Hypothesis \cite{55}.

Two of these last examples, Goodwillie calculus and the Cobordism Hypothesis, are actually applications of \((\infty, n)\)-categories, in which \(k\)-morphisms are invertible for \(k > n\), not just the case where \(n = 1\). Developing models for these more general structures has begun but is still very much a work in progress, especially in terms of comparisons.

The earliest model for \((\infty, n)\)-categories was that of Segal \(n\)-categories; in fact the work of Hirschowitz-Simpson \cite{43} and Pelissier \cite{58} is in this generality. In the last few years, Barwick developed \(n\)-fold complete Segal spaces, and this was the
model used by Lurie [55]. Then Rezk defined $\Theta_n$-spaces, an alternative general-
ization of complete Segal spaces [63]. He conjectured that one could then enrich
categories over $\Theta_{n-1}$-spaces, find Segal category analogues (which would neces-
sarily be somewhat different from the Segal $n$-category versions), and then do a
comparison along the lines of what was done in the $n = 1$ case. Developing and
comparing all these models is work in progress of the author and Rezk, with similar
work being done by Tomesch.

With this overview and motivation given, we turn to understanding ma-
ny of these ideas in more detail in the remaining talks of the workshop.

2. Models for homotopy theories

(Talk given by Boris Chorny)

Take your favorite mathematical objects. If morphisms satisfy associativity and
identity morphisms exist, then we have a category $\mathcal{C}$. We can take some collec-
tion $S$ of morphisms of $\mathcal{C}$, called weak equivalences, that we want to think of as
isomorphisms but may not actually be so.

We can look at Gabriel-Zisman localization [39]. Define a map

$$\gamma: \mathcal{C} \to \mathcal{C}[S^{-1}]$$

such that the maps in $S$ go to isomorphisms. The category $\mathcal{C}[S^{-1}]$ has more maps
than the original $\mathcal{C}$. For example, zig-zags with backward maps in $S$ become mor-
phisms in $\mathcal{C}[S^{-1}]$. The category $\mathcal{C}[S^{-1}]$ is also required to satisfy the following
universal property: if $\delta: \mathcal{C} \to \mathcal{D}$ is a functor such that $\delta(s)$ is an isomorphism in
$\mathcal{D}$ for every map $s$ of $S$, then there is a unique map $\mathcal{C}[S^{-1}] \to \mathcal{D}$ such that the
diagram

$$\begin{array}{ccc}
\mathcal{C} & \xrightarrow{\gamma} & \mathcal{C}[S^{-1}] \\
\downarrow{\delta} & & \downarrow{}
\end{array}$$

commutes.

**Example 2.1.** If $\mathcal{C} = \text{Grp}$ is the category of groups, we can define

$$S = \{G_1 \to G_2 \mid G_1 /[G_1, G_1] \to G_2 /[G_2, G_2]\}$$

where the bracket denotes the commutator subgroup. Then $\text{Grp}[S^{-1}] \simeq \text{Ab}$, the
category of abelian groups.

**Example 2.2.** If $\mathcal{C} = \text{Top}$ is the category of topological spaces, we can consider
$S$ to be the class of homotopy equivalences, or $S_1$ the class of weak homotopy
equivalences. There are thus two homotopy categories to consider, $\text{Top}[S^{-1}]$, which
is too complicated, and $\text{Top}[S_1^{-1}]$, which is usually considered as the homotopy
category.

**Example 2.3.** If $\mathcal{C} = \text{Ch}_{\geq 0}(\mathbb{Z})$ is the category of non-negatively graded chain
complexes of abelian groups, let $S$ be the class of quasi-isomorphisms. Then
$\text{Ch}_{\geq 0}(\mathbb{Z})[S^{-1}] = \text{D}^{\leq 0}(\mathbb{Z})$, the bounded below derived category.

In general, the hom-sets in $\mathcal{C}[S^{-1}]$ may be too big, in that they may form proper
classes rather than sets. There are three possible solutions to this difficulty.
• Use the universe axiom, so that everything “large” becomes small in the next universe. However, this process causes some changes in the original model.

• Sometimes Ore’s condition holds, so any diagram

\[
\begin{array}{ccc}
A & \rightarrow & B \\
\downarrow^{i} & & \downarrow^{p} \\
C & \rightarrow & D
\end{array}
\]

can be completed to a diagram

\[
\begin{array}{ccc}
A & \rightarrow & B \\
\downarrow^{i} & \nearrow & \downarrow^{p} \\
C & \rightarrow & D
\end{array}
\]

For example, this condition helps in the construction of the derived category.

• Consider a model category structure on \( C \).

To get a model category structure, take subcategories of \( C \): \( W \), the weak equivalences, \( Fib \), the fibrations, and \( Cof \), the cofibrations, each containing all isomorphisms. This structure, defined by Quillen in 1967 \([61]\), must satisfy five axioms. These axioms actually guarantee that every two classes together determine the third. If we have a diagram

\[
\begin{array}{ccc}
A & \rightarrow & C \\
\downarrow^{i} & & \downarrow^{p} \\
B & \rightarrow & D
\end{array}
\]

then if the dotted arrow lift exists, we say that \( i \) has the right lifting property with respect to \( p \). If we choose weak equivalences and one of the other classes, then the third is determined by the lifting properties given by axiom 5: \( W \cap Cof \) has the left lifting property with respect to \( Fib \), and \( Cof \) has the left lifting property with respect to \( Fib \cap W \). If the fibrations and cofibrations are specified, then the weak equivalences are determined by this axiom together with the fact that any weak equivalence must be able to be factored as an acyclic cofibration (map which is a cofibration and weak equivalence) followed by an acyclic fibration.

**Example 2.4.** Our two choices of weak equivalences in \( Top \) give two possible model structures. If the weak equivalences are homotopy equivalences, we can define the fibrations to be the Hurewicz fibrations and the cofibrations to be the Borsuk pairs. The result is Strøm's model structure, which is complicated \([68]\).

If we take the weak equivalences to be the weak homotopy equivalences, the cofibrations to be the class of CW inclusions and their retracts, and the fibrations to be Serre fibrations, then we get the standard model structure \([38]\).

**Example 2.5.** For \( Ch_{>0}(\mathbb{Z}) \) with weak equivalences the quasi-isomorphisms, then we can choose the cofibrations to be the injections and the fibrations to be the surjections with projective kernels. Alternatively, one could take the same weak equivalences but choose the fibrations to be all surjections and the cofibrations to be the injections with injective cokernel \([38]\).
Models for a given homotopy theory are not necessarily unique. For example, there is a model category structure on the category $\mathcal{S}ets$ of simplicial sets whose homotopy category is equivalent to $\mathcal{T}op[W^{-1}]$. There is in fact a Quillen equivalence between $\mathcal{T}op$ and $\mathcal{S}ets$: an adjunction such that the left adjoint preserves (acyclic) cofibrations and the right adjoint preserves (acyclic) fibrations.

These techniques can be applied in other settings.

**Example 2.6.** In Voevodsky’s work (e.g., in [57]), he uses the Yoneda embedding $\mathcal{S}m/\vartriangle \to \mathcal{S}ets(\mathcal{S}m/\vartriangle)^{op}$.

**Example 2.7.** The Adams spectral sequence computes stable homotopy classes of maps:

$$\text{Ext}_A(H^*Y, H^*X) \Rightarrow [X, Y]_{st}.$$ The Bousfield-Kan spectral sequence is an unstable version. Farjoun and Zabrodsky generalized it to compute equivariant homotopy classes of maps [31]. In 2004, Bousfield generalized for abstract model categories [29].

3. **Simplicial objects and categories**

(Talk given by Emmanuel Farjoun)

The goals of this talk are to explain:

- why simplicial objects are so often met, and
- why work with simplicial categories and how to get them.

Recall the category $\vartriangle$, which looks like

$$\begin{array}{ccccccc}
0 & \to & 1 & \to & 2 & \to & \cdots
\end{array}$$

The object $[n]$ is the ordered set $\{0, \ldots, n\}$ and the maps are order-preserving and satisfy simplicial relations. We can also take the opposite category $\vartriangle^{op}$.

**Definition 3.1.** A *simplicial object* in a category $\mathcal{C}$ is a functor $\vartriangle^{op} \to \mathcal{C}$.

Historically, Eilenberg and Mac Lane were interested in continuous maps $\Delta^n \to X$ where $\Delta^n$ is the $n$-simplex in $\mathbb{R}^n$ and $X$ is a topological space. But why $\vartriangle$?

The slogan is that $\vartriangle$ (or $\vartriangle^{op}$) is the category of endomorphisms of augmented functors. The objects of this category are functors $a: X \to FX$. We want to “recover” $X$ out of $FX$, $F^2X$, $F^3X$, etc. (This process could be regarded as similar to taking a field extension $k \to \overline{k}$ and trying to recover the original $k$.)

What are the natural transformations between powers of $X$? For example, the two maps $FX \Rightarrow F^2X$ are given by $Fa_X$ and by $a_{FX}$.

**Example 3.2.** Start with the empty space $\phi$ and add a point to make it simpler: $\phi^+$. (Now it is contractible.) We can continue this process of adding a point to get

$$\begin{array}{ccccccc}
\phi & \to & \bullet & \to & \bullet & \to & \Delta & \cdots
\end{array}$$

We also get a map $F^2X \rightarrow FX$, since $FX$ is contractible. Iterating, we just get the category $\vartriangle$.

However, this process does not work for all functors.

**Example 3.3.** In algebra, consider a module $M$. We get a diagram

$$M \Rightarrow FM \Leftarrow F^2M \cdots$$
where the map $i: M \to FM$ sends $m \mapsto m \cdot 1$, and hence there is also a map $Fi: FM \to F^2M$. Sometimes you can recover the module $M$ from this data, but sometimes not.

Recall from the previous talk that a category $C$ with weak equivalences gives rise to $\mathcal{C}[S^{-1}]$, its localization with respect to $S$. The difficulty with this construction is that we don’t keep the limits and colimits that we had in $\mathcal{C}$. For example, suppose we had a pullback diagram in $\mathcal{C}$:

\[
P \rightarrow X \downarrow \quad Y \rightarrow B.
\]

Then in the homotopy category, using subscripts to denote the set of maps being inverted, the diagram

\[
[W, P]_{S^{-1}} \rightarrow [W, X]_{S^{-1}} \rightarrow [W, Y]_{S^{-1}} \rightarrow [W, B]_{S^{-1}}
\]

is not in general a pullback for any object $W$ in $\mathcal{C}$. We want to correct this construction so that it is, taking mapping spaces instead of mapping sets:

\[
\text{Map}_{S^{-1}}(W, P) \rightarrow \text{Map}_{S^{-1}}(W, X) \rightarrow \text{Map}_{S^{-1}}(W, Y) \rightarrow \text{Map}_{S^{-1}}(W, B)
\]

which is a homotopy pullback of spaces. Applying $\pi_0$ gives the previous diagram, but now we can see that it sits in a long exact sequence, so we can see why the above process did not work: there must be correction terms given by higher homotopy groups.

So, how do we define these mapping spaces? The process is called simplicial localization [36].

Given a category $\mathcal{C}$ and a subcategory $S$ of “equivalences” with $\text{ob}(S) = \text{ob}(\mathcal{C})$, we want a simplicial category $L(\mathcal{C}, S)$. Recall that a simplicial category is a category enriched in simplicial sets, so it has objects and, for any pair of objects $A$ and $B$, $\text{Map}(A, B)$ is a simplicial set. We can think of it as the “derived functor of a non-additive functor $F$:

\[
\cdots F^3C \Rightarrow F^2C \Rightarrow FC \Rightarrow \mathcal{C} \supseteq S.
\]

If we invert $S$ at each level, we get a diagram

\[
\cdots F^3C[S^{-1}] \Rightarrow F^2C[S^{-1}] \Rightarrow FC[S^{-1}].
\]

**Theorem 3.4.** [36] $\pi_0L(\mathcal{C}, S) = \mathcal{C}[S^{-1}]$.

Besides universality, the fantastic property of this simplicial localization, or justification for it, as follows. Suppose we start with a model category $\mathcal{M}$. We can use the model structure to get $\text{Map}(X, Y)$ using the cone or cylinder construction, for example $\text{Map}(X, Y)_1 = \text{Hom}_\mathcal{M}(I \otimes X, Y)$. The resulting simplicial category is equivalent to $L(\mathcal{M}, S)$. 
Universality works the same here as it does for the homotopy category: if we have a functor $T: (\mathcal{C}, S) \to \mathcal{D}$, where $\mathcal{D}$ is a simplicial category, such that $T(s)$ is an equivalence for every $s$ in $S$, then there exists a unique simplicial functor $L(\mathcal{C}, S) \to \mathcal{D}$ making the following diagram commute:

$$
\begin{array}{c}
\mathcal{C}, S \\
\downarrow \\
L(\mathcal{C}, S)
\end{array} \xrightarrow{T} 
\begin{array}{c}
\mathcal{D}
\end{array}
$$

Under some conditions, we can equivalently write $L(\mathcal{C}, S)$ as the simplicial category with $L(\mathcal{C}, S)_0$ consisting of diagrams

$$
A \xleftarrow{s} f \xrightarrow{s'} B
$$

and $L(\mathcal{C}, S)_1$ consisting of diagrams

$$
\begin{array}{c}
A \\
\sim \\
\sim \\
\sim \\
\sim \\
\sim \\
\sim \\
\sim \\
\sim \\
\sim \\
\sim \\
\sim \\
\sim \\
\sim \\
B.
\end{array}
$$

This is sometimes called the \textit{hammock localization} \cite{35}.

4. NERVE CONSTRUCTIONS

\textbf{Definition 4.1.} The \textit{nerve} of a small category $\mathcal{C}$ is the simplicial set $\text{nerve}(\mathcal{C})$ defined by

$$
\text{nerve}(\mathcal{C})_n = \text{Hom}_{\text{Cat}}([n], \mathcal{C}).
$$

In other words, the $n$-simplices of the nerve are $n$-tuples of composable morphisms in $\mathcal{C}$. Recall that if $f: \mathcal{C} \to \mathcal{D}$ is an equivalence of categories, then $f$ induces a weak equivalence $\text{nerve}(\mathcal{C}) \to \text{nerve}(\mathcal{D})$.

\textbf{Example 4.2.} Let $\mathcal{C}$ be the category with a single object and only the identity morphism, and let $\mathcal{D}$ be the category with two objects and a single isomorphism between them. Then we can include $\mathcal{C}$ into $\mathcal{D}$ (in two different ways), and this functor is an equivalence of categories. The nerves of the categories $\mathcal{C}$ and $\mathcal{D}$ are both contractible, so we get a homotopy equivalence between them.

However, the converse statement is not true!

\textbf{Example 4.3.} Let $\mathcal{E}$ be the category with two objects, $x$ and $y$, and a single morphism from $x$ to $y$ and no other non-identity morphisms. Then $\text{nerve}(\mathcal{E})$ is contractible, but $\mathcal{E}$ is not equivalent to either $\mathcal{C}$ or $\mathcal{D}$ from the previous example.

The problem here is that weak equivalences of simplicial sets are given by weak homotopy equivalences of spaces after geometric realization, so we don’t remember which direction a 1-simplex pointed. In particular, we don’t remember whether a 1-simplex in the nerve came from an isomorphism in the original category. However, if we restrict to groupoids, where all morphisms are isomorphisms, then the converse statement is true.
In this talk, we'll consider two possible approaches to take after making these observations.

1. We'll look at how to determine whether a simplicial set is the nerve of a groupoid or, more generally, the nerve of a category.
2. We'll define a more refined version of the nerve construction so that it does distinguish isomorphisms from other morphisms.

4.1. Kan complexes and generalizations. Recall some particular useful examples of simplicial sets: the $n$-simplex $\Delta[n] = \text{Hom}(\cdot, [n])$; its boundary $\partial \Delta[n]$, obtained by leaving out the identity map $[n] \to [n]$; and the horns $V[n,k]$, which are obtained by removing the $k$th face from $\partial \Delta[n]$.

For example, when $n = 2$, we can think of $\partial \Delta[2]$ as the (not filled in) triangle $v_1 \downarrow \downarrow v_2 \leftarrow v_0$.

Then the horn $V[2,0]$ looks like $v_1 \downarrow \downarrow v_0 \leftarrow v_2$ whereas $V[2,1]$ looks like $v_1 \downarrow \downarrow v_0 \leftarrow v_2$ and $V[2,2]$ looks like $v_1 \downarrow \downarrow v_0 \leftarrow v_2$.

**Definition 4.4.** A simplicial set $X$ is a *Kan complex* if any map $V[n,k] \to X$ can be extended to a map $\Delta[n] \to X$. In other words, a lift exists in any diagram

$$
\begin{array}{c}
V[n,k] \\
\downarrow \\
\Delta[n] \\
\end{array} \\
\rightarrow \\
\downarrow \\
X
\end{array}
$$

**Proposition 4.5.** The nerve of a groupoid is a Kan complex.

The idea of the proof of this proposition is as follows. Let $G$ be a groupoid. When $n = 2$, having a lift in the diagram

$$
\begin{array}{c}
V[2,1] \\
\downarrow \\
\text{nerve}(G) \\
\end{array} \\
\rightarrow \\
\downarrow \\
\Delta[2]
\end{array}
$$
means that any pair of composable morphisms has a composite. In fact, such a lift will exist for the nerve of any category, not just a groupoid.

However, the 1-simplices in the image of a map \( V[2,0] \to \operatorname{nerve}(G) \) are not composable; they have a common source instead. Therefore, finding a lift to \( \Delta[2] \to X \) could be found if we knew that one of these 1-simplices came from an invertible morphism in \( G \); since \( G \) is a groupoid, this is always the case. Finding a lift for the case \( V[2,2] \) is similar; here the 1-simplices have a common target.

So, we have concluded that a lift exists in a diagram

\[
\begin{array}{ccc}
V[n,k] & \longrightarrow & \operatorname{nerve}(\mathcal{C}) \\
\downarrow & & \downarrow \\
\Delta[n] & & \\
\end{array}
\]

for \( 0 \leq k \leq n \) if \( \mathcal{C} \) is a groupoid but only for \( 0 < k < n \) if \( \mathcal{C} \) is any category.

However, since composition in a category is unique, lifts in the above diagram will also be unique.

**Proposition 4.6.** A Kan complex \( K \) is the nerve of a groupoid if and only if the lift in each diagram

\[
\begin{array}{ccc}
V[n,k] & \longrightarrow & K \\
\downarrow & & \downarrow \\
\Delta[n] & & \\
\end{array}
\]

is unique for every \( 0 \leq k \leq n \).

Generalizing the above observation, we get the following.

**Definition 4.7.** A simplicial set \( K \) is an inner Kan complex or a quasi-category if a lift exists in any diagram

\[
\begin{array}{ccc}
V[n,k] & \longrightarrow & X \\
\downarrow & & \downarrow \\
\Delta[n] & & \\
\end{array}
\]

for \( 0 < k < n \).

**Proposition 4.8.** A quasi-category is the nerve of a category if and only if these lifts are all unique.

4.2. Classifying diagrams. Recall that a simplicial space or bisimplicial set is a functor \( \Delta^{op} \to \text{SSets} \).

**Definition 4.9.** The classifying diagram \( \mathcal{N}\mathcal{C} \) of a category \( \mathcal{C} \) is the simplicial space defined by

\[
(\mathcal{N}\mathcal{C})_n = \operatorname{nerve}(\operatorname{iso}(\mathcal{C}^{[n]}))
\]

where \( \mathcal{C}^{[n]} \) denotes the category of functors \([n] \to \mathcal{C}\) whose objects are length \( n \) chains of composable morphisms in \( \mathcal{C} \), and where \( \operatorname{iso} \) denotes the maximal subgroupoid functor.
What does this definition mean? When \( n = 0 \), \((NC)_0 = \text{nerve} (\text{iso}(C))\) is the nerve of the maximal subgroupoid of \( C \). In particular, this simplicial set only picks up information about isomorphisms in \( C \). When \( n = 1 \), we have \((NC)_1 = \text{nerve} (\text{iso}(C^{[1]}))\). The objects of \( \text{iso}(C^{[1]}) \) are morphisms in \( C \), and the morphisms of \( \text{iso}(C^{[1]}) \) are pairs of morphisms making the appropriate square diagram commute. More generally, \((NC)_{n,m}\) is the set of diagrams of the form

\[
\begin{array}{cccccc}
\sim & \sim & \cdots & \sim & \sim & \sim \\
\downarrow & \downarrow & \cdots & \downarrow & \downarrow \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
\downarrow & \downarrow & \cdots & \downarrow & \downarrow \\
\sim & \sim & \cdots & \sim & \sim \\
\end{array}
\]

where there are \( n \) horizontal arrows in each row and \( m \) vertical arrows in each column.

**Example 4.10.** If \( C \) is a groupoid, then up to homotopy, \( NC \) is a constant simplicial space and has the homotopy type of the nerve of \( C \).

**Example 4.11.** Let \( C \) be the category \( \mathcal{E} \) from above. Then \((NC)_0\) has the homotopy type of two points and \((NC)_1\) has the homotopy type of three points. In particular, the two sets are not the same, and therefore the classifying diagram is not levelwise equivalent to the category with one object and one morphism, since it is a groupoid.

We have several nice facts about classifying diagrams of categories.

1. The homotopy types of the simplicial sets \((NC)_n\) are determined by \((NC)_0\) and \((NC)_1\), in that

\[(NC)_n \simeq (NC)_1 \times_{(NC)_0} \cdots \times_{(NC)_0} (NC)_1.\]

This idea will lead to the definition of Segal space.

2. The subspace of \((NC)_1\) arising from isomorphisms in \( C \) is weakly equivalent to \((NC)_0\). This idea will lead to the definition of complete Segal space.

At this point we can make a connection to the previous subsection. Notice that the simplicial set \((NC)_{*,0}\) is just the nerve of \( C \). In particular, it is a quasi-category. This property will continue to hold for more general complete Segal spaces.

5. **Segal’s approach to loop spaces**

(Talk given by Matan Prezma)

We begin by recalling the definition of a loop space.

**Definition 5.1.** Given a space \( Y \) with base point \( y_0 \), its loop space is

\[\Omega Y = \{ \gamma : [0, 1] \to Y \mid \gamma(0) = y_0 = \gamma(1) \}.\]
Whenever we have loops $\alpha$ and $\beta$ in $\Omega Y$, we can compose them (via concatenation) to get a loop $\alpha \ast \beta$. While this operation is not strictly associative, we do have that the loop $\alpha \ast (\beta \ast \gamma)$ is homotopic to the loop $(\alpha \ast \beta) \ast \gamma$. In particular, if $1$ denotes the constant loop, then for every $\alpha \in \Omega Y$, there exists a loop $\alpha^{-1}$ such that $\alpha \ast \alpha^{-1}$ is homotopic to $1$.

5.1. **Work of Kan.** Consider $\Omega Y$ for a pointed connected space $Y$. Applying the singular functor gives a simplicial set $\text{Sing}(Y)$ which is homotopy equivalent to $\text{red}(\text{Sing}(Y))$, a reduced simplicial set, or one with only one vertex.

For any reduced simplicial set $S$, we can apply the Kan loop group functor $G$ to get a simplicial group $G_S$. In particular, $(G S)_0 = F S_1$, the free group on the set $S_1$. (Note that the maps in this simplicial group are complicated.)

Putting these two ideas together, we can obtain that $|G \text{red}(\text{Sing} Y)| \simeq \Omega Y$.

In other words, the topological group on the left-hand side is a rigidification of $\Omega Y$.

5.2. **Work of Stasheff.** This work originates with the following question: When is a space $X$ homotopy equivalent to $\Omega Y$ for some space $Y$? To answer this question, we get the idea of $A_\infty$-spaces.

The base case is where the space $X$ is equipped with a pointed map $\mu: W \times X \to X$, such that the base point of $X$ behaves like a unit element. In this case we say that $X$ is an $A_2$-space.

We can then consider when this map $\mu$ comes equipped with a homotopy between $\mu \circ (1 \times \mu)$ and $\mu \circ (\mu \times 1)$, so that the diagram

\[
\begin{array}{ccc}
X \times X \times X & \xrightarrow{\mu \times 1} & X \times X \\
\downarrow{1 \times \mu} & & \downarrow{\mu} \\
X \times X & \xrightarrow{\mu} & X
\end{array}
\]

commutes up to homotopy. In this case, $X$ is an $A_3$-space.

Now, given an $A_3$-space $X$, we could ask what the next level of associativity is, in order to define an $A_4$-space. We would need to have a relationship between the different ways of parenthesizing four elements, say $\alpha, \beta, \gamma$, and $\delta$, so we need to consider the diagram

\[
\begin{array}{ccc}
((\alpha \beta)\gamma)\delta & \xrightarrow{\alpha((\beta\gamma)\delta)} & \alpha((\beta\gamma)\delta) \\
((\alpha \beta)\gamma)\delta & \xrightarrow{\alpha((\beta\gamma)\delta)} & \alpha((\beta\gamma)\delta).
\end{array}
\]

In other words, we have a map $\mu_4: S^1 \to \text{Map}_*(X^4, X)$. If $X$ is a loop space, one can see that this map is nullhomotopic. Therefore, we say that $X$ is an $A_4$-space if $\mu_4$ is nullhomotopic.

We can then continue, so an $A_5$-space has the map from the boundary of some 3-dimensional diagram to the space nullhomotopic, and we can define similarly in higher dimensions. An $A_\infty$-space is an $A_n$-space for all $n$. 
Theorem 5.2. If $X$ is a CW complex, then $X \simeq \Omega Y$ for some $Y$ if and only if:

1. $\pi_0 X$ is a group, and
2. $X$ is an $A_\infty$-space.

5.3. Work of Segal. Assume that $X$ is a homotopy associative $H$-space (so that it is $A_3$). Then $X$ is a monoid in $\text{Ho}(\mathcal{Top})$, the homotopy category of spaces. Thus, the nerve of $X$ is a simplicial object in $\text{Ho}(\mathcal{Top})$, with nerve($X$)$_1 = X$ and nerve($X$)$_2 = X \times X$. So, we get a functor $\Delta^{op} \to \text{Ho}(\mathcal{Top})$.

If a lift exists in the diagram

$$
\begin{array}{ccc}
\mathcal{Top} & \to & \text{Ho}(\mathcal{Top}) \\
\downarrow & & \downarrow \\
\Delta^{op} & \to & \text{Ho}(\mathcal{Top})
\end{array}
$$

making it commutative up to natural isomorphism, then the space $X$ has a classifying space. In other words, $X \simeq \Omega Y \simeq G$ with $BG \simeq Y$.

Consider the maps in $\Delta$ of the form $\alpha_i : [1] \to [n]$ given by $0 \mapsto i - 1$ and $1 \mapsto i$.

Theorem 5.3. Let $X$ be a CW complex. Then $X \simeq \Omega Y$ if and only if

1. $\pi_0(X)$ is a group, and
2. there exists a simplicial space $A$ such that
   
   i. $A_0 = \ast$,
   
   ii. $A_1 \simeq X$, and
   
   iii. for every $n \geq 2$ the map $(\alpha_1)_* \cdots (\alpha_n)_* : A_n \to (A_1)^n$ is a homotopy equivalence.

In addition, $\Omega|A| \simeq X$ and $|A| \simeq Y$.

6. Complete Segal spaces

(Talk given by Ilan Barnea)

Consider the category $\text{SSets}^{\Delta^{op}} = \text{Sets}^{\Delta^{op} \times \Delta^{op}}$ of simplicial spaces. We can regard $\text{SSets}$ as a subcategory of $\text{SSets}^{\Delta^{op}}$, via the functor that takes a simplicial set $K$ to the constant simplicial space with $K$ at each level and all face and degeneracy maps the identity.

Recall that the category of simplicial spaces is monoidal under the cartesian product. It also has a simplicial structure, where for a simplicial set $K$ and simplicial space $X$, we have $(K \times X)_n = K \times X_n$. For simplicial spaces $X$ and $Y$ the simplicial set $\text{Map}(X,Y)$ is given by the adjoint relation

$$\text{Map}(X,Y)_n = \text{Hom}_{\text{SSets}}(\Delta[n], \text{Map}(X,Y)) = \text{Hom}_{\text{SSets}^{\Delta^{op}}}(\Delta[n] \times X, Y).$$

There is another functor which takes a simplicial set $K$ to a simplicial space $F(K)$, given by $F(K)_n = K_n$. Let $F(n) = F(\Delta[n])$. Then $\text{Map}(F(n), X) \cong X_n$. We use this functor in the description of the cartesian closed structure on simplicial spaces, where

$$(Y^X)_n = \text{Map}(F(n), Y^X) \cong \text{Map}(F(n) \times X, Y).$$

There is a model structure on the category of simplicial spaces where weak equivalences and cofibrations are levelwise, and fibrations have the left lifting property with respect to the maps which are both cofibrations and weak equivalences.
VIII, 2.4]. In this case, this model structure coincides with the Reedy model structure \[62\], \[42\, 15.8.7, 15.8.8\].

In fact, the category of simplicial spaces has the additional structure of a simplicial model category, so that if \(X\) is cofibrant and \(Y\) is fibrant, \(\text{Map}(X,Y)\) is the “right” definition of mapping space, in that the mapping spaces are homotopy invariant.

Recall that if \(f : X \to Y\) is a fibration and \(Z\) is any cofibrant simplicial space, then \(\text{Map}(Z,X) \to \text{Map}(Z,Y)\) is a fibration. Letting \(Z = F(n)\), we get that \(X_n \to Y_n\) is a fibration for any \(n\), and if \(X\) is fibrant, it follows that each \(X_n\) is a Kan complex. Similarly, if \(f : X \to Y\) is a cofibration and \(Z\) is fibrant, then \(\text{Map}(Y,Z) \to \text{Map}(X,Z)\) is a fibration. Using the cofibration \(F(0) \amalg F(0) \to F(1)\), we get that \(d_1 \times d_0 : Z_1 \to Z_0 \times Z_0\) is a fibration.

**Definition 6.1.** [64] A simplicial space \(X\) is a Segal space if it is Reedy fibrant and the Segal maps

\[ W_k \to \underbrace{W_1 \times W_0 \cdots \times W_0 W_1}_{k} \]

are weak equivalences.

Define the simplicial space \(G(k) \subseteq F(k)\) by

\[ G(k) = \bigcup_{i=1}^{k} \alpha^{i} F(1) \subseteq F(k). \]

The Segal map in the previous definition is given by

\[ \text{Map}(F(k), W) \to \text{Map}(G(k), W). \]

By the above comments, this map is always a fibration; we want to require it to be a weak equivalence. In particular, we have \(\text{Map}(F(k), W)_0 \to \text{Map}(G(k), W)_0\) is surjective, so we can “compose” 0-simplices of \(W_1\).

For a Segal space \(W\), define the objects of \(W\) to be \(\text{ob}(W) = W_{0,0}\). Given \(x, y \in \text{ob}(W)\), define the mapping space between them to be the pullback

\[ \text{map}_W(x, y) \to W_1 \]

\[ \{(x, y)\} \to W_0 \times W_0. \]

Given an object \(x\), define \(\text{id}_x = s_0(x) \in \text{map}_W(x, x)\). We say that \(f, g \in \text{map}_W(x, y)\) are homotopic if \([f] = [g] \in \pi_0 \text{map}_W(x, y)\).

If \(g \in \text{map}_W(y, z)\) and \(f \in \text{map}_W(x, y)\), there exists \(k \in W_{2,0}\) such that \(k \mapsto (f, g)\) under the map \(W_{2,0} \to W_{1,0} \times W_{1,0}\). Then write \((g \circ f)_k = d_1(k)\), a composite of \(g\) and \(f\) given by \(k\).

We can define the homotopy category \(\text{Ho}(W)\) to have objects \(W_{0,0}\) and morphisms given by

\[ \text{Hom}_{\text{Ho}(W)}(x, y) = \pi_0 \text{map}_W(x, y). \]

If \(f \in \text{map}_W(x, y)\) and \([f]\) is an isomorphism in \(\text{Ho}(W)\), then \(f\) is a homotopy equivalence. Notice in particular that for any object \(x\), \(\text{id}_x = s_0(x)\) is a homotopy equivalence. Furthermore, if \([f] = [g] \in \pi_0 \text{map}_W(x, y)\), then \(g\) is a homotopy equivalence if and only if \(g\) is a homotopy equivalence. Define \(W_{\text{heq}} \subseteq W_1\) to be the components consisting of homotopy equivalences, and notice that \(s_0 : W_0 \to W_{\text{heq}}\).
Definition 6.2. [64] Let $W$ be a Segal space. If $s_0: W_0 \to W_{heq}$ is a weak equivalence, then $W$ is complete.

Let $\mathcal{M}$ be a model category and $T$ a set of maps in $\mathcal{M}$. A $T$-local object in $\mathcal{M}$ is a fibrant object $W$ in $\mathcal{M}$ such that $\text{Map}(B, W) \to \text{Map}(A, W)$ is a weak equivalence for every $f: A \to B$ in $T$. A $T$-local equivalence $g: X \to Y$ in $\mathcal{M}$ is a map such that $\text{Map}(Y, W) \to \text{Map}(X, W)$ is a weak equivalence for every $T$-local object $W$.

If $\mathcal{M}$ is a left proper and cellular model category [22, 13.1.1, 12.1.1], then we can define a new model category structure $L_T\mathcal{M}$ on the same category with the same cofibrations, but with weak equivalences the $T$-local equivalences and fibrant objects the $T$-local objects. If $f: X \to Y$ is a map with both $X$ and $Y$ $T$-local, then $f$ is a weak equivalence in $\mathcal{M}$ if and only if $f$ is a weak equivalence in $L_T\mathcal{M}$.

In the case of simplicial spaces, we first localize with respect to the maps $\{\varphi_k: G(k) \to F(k)\}$ to get a model category whose fibrant objects are the Segal spaces. Then consider the category $I$ with two objects and a single isomorphism between them. Define $E = F(\text{nerve}(I))$. There is a map $F(1) \to E$ inducing $\text{Map}(E, W) \to \text{Map}(F(1), W) = W_1$ whose image is in $W_{heq}$. In fact, $\text{Map}(E, W) \to W_{heq}$ is a weak equivalence. Using the map $E \to F(0)$, we get a map $W_0 \to \text{Map}(E, W)$ which is a weak equivalence if and only if $s_0: W_0 \to W_{heq}$ is a weak equivalence. Thus, we want to localize with respect to the map $E \to F(0)$ to get a model category denoted $\mathcal{CSS}$ whose fibrant objects are the complete Segal spaces. It follows that a map $f: X \to Y$ of complete Segal spaces is a weak equivalence in $\mathcal{CSS}$ if and only if $f$ is a levelwise weak equivalences of simplicial sets.

7. Segal categories and comparisons

We begin with the model structure on simplicial categories. Recall that, given a simplicial category $\mathcal{C}$, we can apply $\pi_0$ to the mapping spaces to obtain an ordinary category $\pi_0\mathcal{C}$, called the category of components of $\mathcal{C}$.

Theorem 7.1. [20] There is a model structure on the category of small simplicial categories such that the weak equivalences are the simplicial functors $f: \mathcal{C} \to \mathcal{D}$ such that for any objects $x$ and $y$ the map $\text{Map}_\mathcal{C}(x, y) \to \text{Map}_\mathcal{D}(f x, f y)$ is a weak equivalence of simplicial sets, and the functor $\pi_0 f: \pi_0 \mathcal{C} \to \mathcal{D}$ is an equivalence of categories. The fibrant objects are the simplicial categories whose mapping spaces are Kan complexes.

These weak equivalences are often called Dwyer-Kan equivalences, since they were first defined by Dwyer and Kan in their investigation of simplicial categories.

The idea behind Segal categories is that they are an “intermediate” version between simplicial categories and complete Segal spaces. They are like nerves of simplicial categories but with composition only defined up to homotopy. They are Segal spaces but with a “discreteness” condition in place of “completeness.”

Definition 7.2. A Segal precategory is a simplicial space $X$ such that $X_0$ is a discrete simplicial set. It is a Segal category if the Segal maps $\varphi_k: X_k \to X_{1 \times \cdots \times X_0 \times \cdots \times X_0 \times X_1}$ are weak equivalences of simplicial sets for every $k \geq 2$. 
Let \( \mathcal{S} \mathcal{S}ets^{\Delta^{op}_{disc}} \) denote the category of Segal precategories. There is an inclusion functor
\[
I: \mathcal{S} \mathcal{S}ets^{\Delta^{op}_{disc}} \rightarrow \mathcal{S} \mathcal{S}ets^{\Delta^{op}}.
\]
However, unlike for \( \mathcal{S} \mathcal{S}ets^{\Delta^{op}} \), there is no model structure with levelwise weak equivalences and cofibrations monomorphisms. For example, the map of doubly constant simplicial spaces \( \Delta[0] \amalg \Delta[0] \rightarrow \Delta[0] \) cannot possibly be factored as a cofibration followed by an acyclic fibration. Therefore, we cannot obtain our model structure for Segal categories by localizing such a model structure, as we did for Segal spaces.

However, given a Segal precategory, we can use the inclusion functor to think of it as an object in the Segal space model category and localize it to obtain a Segal space. Generally, this procedure will not result in a Segal category, since it won’t preserve discreteness of the 0-space. However, one can define a modification of this localization that does result in a Segal space which is also a (Reedy fibrant) Segal category. Given a Segal precategory \( X \), we denote this “localization” \( LX \). Notice that it can be defined functorially.

Since \( LX \) is a Segal space, it has objects (given by \( X_0 \), since it is discrete) and mapping spaces \( \text{map}_{LX}(x, y) \) for any \( x, y \in X_0 \). It also has a homotopy category \( \text{Ho}(LX) \).

**Definition 7.3.** A map \( f: W \rightarrow Z \) of Segal spaces is a Dwyer-Kan equivalence if:
\[
(1) \text{map}_W(x, y) \rightarrow \text{map}_Z(fx, fy) \text{ is a weak equivalence of simplicial sets for any objects } x \text{ and } y \text{ of } W, \text{ and}
\]
\[
(2) \text{Ho}(W) \rightarrow \text{Ho}(Z) \text{ is an equivalence of categories.}
\]

**Proposition 7.4.** A map \( f: W \rightarrow Z \) of Segal spaces is a Dwyer-Kan equivalences if and only if it is a weak equivalence in \( \text{CSS} \).

**Definition 7.5.** A map \( f: X \rightarrow Y \) of Segal precategories is a Dwyer-Kan equivalence if the induced map of Segal categories (Segal spaces) \( LX \rightarrow LY \) is a Dwyer-Kan equivalence in the sense of the previous definition.

**Theorem 7.6.** There is a model structure \( \text{SeCat}_c \) on the category of Segal precategories such that
\[
(1) \text{the weak equivalences are the Dwyer-Kan equivalences,}
\]
\[
(2) \text{the cofibrations are the monomorphisms (so that every object is cofibrant), and}
\]
\[
(3) \text{the fibrant objects are the Reedy fibrant Segal categories}
\]

We also want a model structure that looks more like a localization of the projective model structure.

**Theorem 7.7.** There is a model structure \( \text{SeCat}_f \) on the category of Segal precategories such that
\[
(1) \text{the weak equivalences are the Dwyer-Kan equivalences, and}
\]
\[
(2) \text{the fibrant objects are the projective fibrant Segal categories.}
\]

We begin by looking at the comparison between Segal categories and complete Segal spaces.

**Proposition 7.8.** The inclusion functor \( I: \text{SeCat}_c \rightarrow \text{CSS} \) has a right adjoint \( R: \text{CSS} \rightarrow \text{SeCat}_c \).
We can define the functor $R$ as follows. Suppose that $W$ is a simplicial space. Define $RW$ to be the pullback

$$
\begin{array}{ccc}
RW & \longrightarrow & \cosk_0(W_{0,0}) \\
\downarrow & & \downarrow \\
W & \longrightarrow & \cosk_0(W_0).
\end{array}
$$

For example, at level 1 we get

$$
\begin{array}{ccc}
(RW)_1 & \longrightarrow & W_{0,0} \times W_{0,0} \\
\downarrow & & \downarrow \\
W_1 & \longrightarrow & W_0 \times W_0.
\end{array}
$$

If $W$ is a complete Segal space, then $RW$ is a Segal category; for example at level 2 we get

$$
\begin{array}{ccc}
(RW)_1 \times (RW)_0 & \longrightarrow & W_{0,0} \times W_{0,0} \times W_{0,0} \\
\downarrow & & \downarrow \\
W_1 \times W_0 \times W_1 & \longrightarrow & W_0 \times W_0 \times W_0.
\end{array}
$$

**Theorem 7.9.** [24] The adjoint pair $I : \mathbf{SeCat}_c \leftrightarrows \mathbf{CSS} : R$ is a Quillen equivalence.

**Idea of proof.** Showing that this adjoint pair is a Quillen pair is not hard, since cofibrations are exactly monomorphisms in each model category, and the weak equivalences in $\mathbf{SeCat}_c$ are defined in terms of Dwyer-Kan equivalences in $\mathbf{CSS}$. To prove that it is a Quillen equivalence, need to show that if $W$ is a complete Segal space, the map $RW \to W$ is a Dwyer-Kan equivalence of Segal spaces. □

Now we consider the comparison with simplicial categories. We have the simplicial nerve functor $N : \mathbf{SC} \to \mathbf{SeCat}_f$.

**Proposition 7.10.** [24] The simplicial nerve functor $N$ has a left adjoint $F : \mathbf{SeCat}_f \to \mathbf{SC}$.

**Idea of proof.** Segal categories, at least fibrant ones, are local objects in the Segal space model structure (or here, the analogue of the Segal space model structure but where we localize the projective model structure on simplicial spaces, rather than the Reedy structure). By definition, the Segal maps for a Segal category are weak equivalences. Nerves of simplicial categories are “strictly local” objects, in that the Segal maps are actually isomorphisms. A more general result can be proved [21] about the existence of a left adjoint functor to the inclusion functor of strictly local objects into the category of all objects, i.e., a rigidification functor. □

**Theorem 7.11.** [24] The adjoint pair $N : \mathbf{SC} \leftrightarrows \mathbf{SeCat}_f$ is a Quillen equivalence.

This result is much harder to prove than the previous comparison. We need the model structure $\mathbf{SeCat}_f$ here since it is more easily compared to $\mathbf{SC}$. For example, in both cases the fibrant objects have mapping spaces which are Kan complexes, and not all monomorphisms are cofibrations. The Quillen equivalence was proved first in the fixed object case, where methods of algebraic theories can be applied [22]. then we can generalize to the more general case as stated in the theorem.
Hence, we get a chain of Quillen equivalences
\[ \mathcal{SC} \cong \mathcal{SeCat}_f \cong \mathcal{SeCat}_c \cong \mathcal{CSS}. \]

8. QUASI-CATEGORIES

(Talk given by Yonatan Harpaz)

Consider topological spaces up to weak homotopy equivalence, i.e., \( f : X \to Y \) which induces \( \pi_n(X) \cong \pi_n(Y) \) for all \( n \). J.H.C. Whitehead proved:

1. Every space is weakly equivalent to a CW complex.
2. If two CW complexes are weakly homotopy equivalent, then they are actually homotopy equivalent.

Between simplicial sets and topological spaces, there is a geometric realization functor \(|-|: \mathcal{SSets} \to \mathcal{Top}|\).

Recall in a model category that an object \( X \) is fibrant if the map \( X \to \ast \) is a fibration. It is cofibrant if \( \phi \to X \) is a cofibration.

In a model category, we want to define what we mean by ”\( X \times I \)” in order to define a “homotopy” given by \( X \times I \to Y \).

Define a map \( S \to T \) of simplicial sets to be a weak equivalence if its geometric realization is a weak homotopy equivalence of spaces. In fact, we have an adjoint pair
\[ |-|: \mathcal{SSets} \leftrightarrows \mathcal{Top}: \text{Sing}. \]

Therefore, given a simplicial set \( S \) we have a map \( S \to \text{Sing}(|S|) \), and given a topological space \( X \) we have a map \(|\text{Sing}(X)| \to X \), and these are weak equivalences for \( S \) and \( T \) sufficiently nice. The left adjoint preserves (acyclic) cofibrations, and the right adjoint preserves (acyclic) fibrations. The consequence of this adjointness is that Kan complexes, which can be written as \( \text{Sing}(|S|) \) for some \( S \), are good models for spaces.

In the world of topological categories, we say that a functor \( f: \mathcal{C} \to \mathcal{D} \) is a weak equivalence if it induces

1. \( \text{Hom}(X, Y) \to \text{Hom}(fX, fY) \) is a weak homotopy equivalence, and
2. an equivalence on \( \pi_0 \).

We can model topological categories by simplicial categories. The fibrant simplicial categories have mapping spaces Kan complexes, it is less clear how to describe cofibrant objects.

We want to define another model: quasi-categories, which fit into a chain of adjoints
\[ \mathcal{SSets} \leftrightarrows \mathcal{SCat} \leftrightarrows \mathcal{TopCat}. \]

We consider the adjoint pair
\[ C^\Delta: \mathcal{SSets} \leftrightarrows \mathcal{SCat}: \mathcal{N}^\Delta. \]

We first consider the discrete version: \( C: \mathcal{SSets} \leftrightarrows \mathcal{Cat}: \text{nerve} \). Here we have \( \text{ob}(C(\Delta^n)) = \{0, \ldots, n\} \) and \( \text{Hom}(i, j) = \ast \) for \( i \leq j \) and is empty otherwise. The nerve is given by \( \text{nerve}(C) \to \mathcal{C} \).

In the simplicial case, we still have \( \text{ob}(C^\Delta(\Delta^n)) = \{0, \ldots, n\} \), but for \( i \leq j \) we now have
\[ \text{Hom}(i, j) = (\Delta^1)^{\{i+1, \ldots, j-1\}}. \]
(Note that \((\Delta^1)^\phi = \ast\).) Composition is given by
\[
(\Delta^1)^{(i+1, \ldots, j-1)} \times (\Delta^1)^{(j+1, \ldots, k-1)} \to (\Delta^1)^{(i+1, \ldots, k+1)}.
\]
Similarly to before, we have \(N^\Delta(C) = \text{Hom}_{\mathcal{SCat}}(C^\Delta(\Delta^n), C)\). This functor \(N^\Delta\) is called the coherent nerve.

Using these functors, we define a new model structure on the category \(\mathcal{SSets}\). The new version of \(S \times I\) will use \(I = \text{nerve}(\bullet \leftarrow \bullet) =: E\). The fibrant objects will be the simplicial sets which look like coherent nerves of fibrant simplicial categories, or quasi-categories, as given in Definition 4.8.

Suppose that \(C\) is a fibrant simplicial category. Then there is a lift

\[
\begin{array}{ccc}
V[n, k] & \longrightarrow & N^\Delta(C) \\
\downarrow & & \downarrow \\
\Delta^n & \leftrightarrow & \Delta^n
\end{array}
\]

if and only if there is a lift

\[
\begin{array}{ccc}
C^\Delta(\Lambda^n_k) & \longrightarrow & C \\
\downarrow & & \downarrow \\
C^\Delta(\Delta^n) & \leftrightarrow & C^\Delta(\Delta^n)
\end{array}
\]

What is \(C^\Delta(\Delta^n)\)? It will have the same objects as \(C^\Delta(\Delta^n)\), since \(V[n, k]\) has the same vertices as \(\Delta^n\). Furthermore, \(\text{Hom}(i, j)\) will be the same when \((i, j) \neq (0, n)\), but will change in this one case. For example, when \(n = 2\), we get a new element in \(\text{Hom}(0, 2)\). But, the change is given by an acyclic cofibration of simplicial sets.

So, to get a lift, we know where to send objects, but we just have one mapping space missing. But, this still works since these are Kan complexes.

\section{Comparison on quasi-categories with other models}

(Talk given by Tomer Schlank)

Kan complexes have the property that
\[
|\text{Map}_{\mathcal{SSets}}(X, Y)| = |\text{Map}_{\mathcal{T}_{op}}(|X|, |Y|)|.
\]

Having a lift in any diagram of the form

\[
\begin{array}{ccc}
V[n, k] & \longrightarrow & X \\
\downarrow & & \downarrow \\
\Delta^n & \leftrightarrow & \Delta^n
\end{array}
\]

for \(0 \leq k \leq n\) encodes spaces. If we consider only \(0 < k < n\) and require the lift to be unique, then such diagrams encode categories. Combining the two, taking the existence of a lift for \(0 < k < n\), encodes simplicial categories.

We want a model structure on the category of simplicial sets whose fibrant objects are precisely the quasi-categories. So, we want each \(V[n, k] \to \Delta^n\) to be an acyclic cofibration. On the other hand, when \(k = 0\) or \(k = n\), we don’t want to require it to be a weak equivalence.
Definition 9.1. If $X$ and $Y$ are simplicial sets, then a map $f : X \to Y$ is a categorical equivalence if $C^\Delta(X) \to C^\Delta(Y)$ is a weak equivalence of simplicial categories.

Recall that maps between model categories are pairs of functors

$F : \mathcal{M}_1 \rightleftarrows \mathcal{M}_2 : G$

which are adjoint, so that $\text{Hom}(FX, Y) \cong \text{Hom}(X, GY)$. Furthermore, we require that $F$ preserves cofibrations and acyclic cofibrations, which is true if and only if $G$ preserves fibrations and acyclic fibrations. Such a Quillen pair induces a map on homotopy categories $\text{Ho}(\mathcal{M}_1) \to \text{Ho}(\mathcal{M}_2)$ given by $X \mapsto F(X^{cot})$. If this map is an equivalence, we have a Quillen equivalence. Equivalently, if $X$ is fibrant in $\mathcal{M}_1$ and $Y$ is fibrant in $\mathcal{M}_2$, then the isomorphism $\text{Hom}(FX, Y) \leftrightarrow \text{Hom}(X, GY)$ takes weak equivalences to weak equivalences. We want the adjoint pair $C^\Delta : \text{Sets}^\Delta \rightleftarrows \text{SCat} : N^\Delta$ to be a Quillen equivalence.

Suppose we have a Quillen pair $F : \mathcal{C} \rightleftarrows \mathcal{D} : G$ with $\mathcal{C}$ a left proper, combinatorial model category with weak equivalences preserved under filtered colimits. Let $CF$ be a class of morphisms (in fact, cofibrations) in $\mathcal{D}$, and assume that $F(CF) \subseteq \text{cof}(\mathcal{C})$. Assume that $F(CF^\perp) \subseteq \text{we}(\mathcal{C})$, where $CF^\perp$ denotes the class of maps with the right lifting property with respect to the maps in $CF$. This gives a left proper, combinatorial model structure on $\mathcal{D}$ so that $(F, G)$ is a Quillen pair. This method gives a model structure on $\text{SSets}^\Delta$.

To show that $(C^\Delta, N^\Delta)$ is a Quillen equivalence, we need to show that if $X$ is (cofibrant) simplicial set and $Y$ is a fibrant simplicial category, then $C^\Delta(X) \to Y$ is a weak equivalence if and only if $\text{weak equivalence}$. The idea is to compose this last map with the counit $C^\Delta(N^\Delta(Y)) \to Y$ and show that the counit is a weak equivalence.

10. Applications: Homotopy-theoretic constructions and derived Hall algebras

Having model categories whose objects are “homotopy theories” enables us to understand the “homotopy theory of homotopy theories.” We can compare to ad-hoc constructions already developed for model categories and verify them, then make new ones. An example is a definition of the “homotopy fiber product” of model categories.

Definition 10.1. Let

$\mathcal{M}_1 \xrightarrow{F_1} \mathcal{M}_3 \xleftarrow{F_2} \mathcal{M}_2$

be a diagram of left Quillen functors of model categories. Define their weak homotopy fiber product $\mathcal{M}_w$ to have objects 5-tuples $(x_1, x_2, x_3; u, v)$ where each $x_i$ is an object of $\mathcal{M}_1$ and $u$ and $v$ are maps in $\mathcal{M}_3$ given by

$F_1(x_1) \xrightarrow{u} x_3 \xleftarrow{v} F_2(x_2)$.

Morphisms

$(x_1, x_2, x_3; u, v) \to (y_1, y_2, y_3; w, z)$
are given by triples \((f_1, f_2, f_3)\) where \(f_i : x_i \to y_i\) and the diagram

\[
\begin{array}{ccc}
F_1(x_1) & \xrightarrow{u} & x_3 & \xleftarrow{v} & F_2(x_2) \\
\downarrow F_1(f_1) & & & & \downarrow F_2(f_2) \\
F_1(y_1) & \xrightarrow{w} & y_3 & \xleftarrow{z} & F_3(x_3)
\end{array}
\]

commutes. The homotopy fiber product \(\mathcal{M} = \mathcal{M}_1 \times_{\mathcal{M}_3} \mathcal{M}_2\) is the full subcategory of \(\mathcal{M}_w\) whose objects satisfy the condition that \(u\) and \(v\) are weak equivalences in \(\mathcal{M}\).

There is a model structure on the category \(\mathcal{M}_w\) in which weak equivalences and cofibrations are levelwise. The subcategory \(\mathcal{M}\) does not have a model structure, as the additional property on \(u\) and \(v\) is not preserved by all limits and colimits. In some cases, however, we can localize the model structure on \(\mathcal{M}_w\) so that the fibrant objects are in \(\mathcal{M}\). Otherwise, we can just think of \(\mathcal{M}\) as a category with weak equivalences.

We want to consider this construction in the context of the homotopy theory of homotopy theories, in particular in the setting of complete Segal spaces. To translate, we have two choices, using the functor \(L_C\) that takes a model category to a complete Segal space. We can either first apply \(L_C\) to the diagram and then take the homotopy pullback of complete Segal spaces \(L_C \mathcal{M}_1 \times L_C \mathcal{M}_3 L_C \mathcal{M}_2\), or we can take the complete Segal space associated to the homotopy fiber product, \(L_C \mathcal{M}\).

**Proposition 10.2.** \([19]\) The complete Segal spaces \(L_C \mathcal{M}\) and \(L_C \mathcal{M}_1 \times L_C \mathcal{M}_3 L_C \mathcal{M}_2\) are weakly equivalent.

This result verifies that the definition of the homotopy fiber product of model categories is in fact the correct one, from a homotopy-theoretic point of view.

We now consider an application of this construction, that of derived Hall algebras. Let \(\mathcal{A}\) be an abelian category with \(\text{Hom}(X, Y)\) and \(\text{Ext}^1(X, Y)\) finite for any objects \(X\) and \(Y\) of \(\mathcal{A}\).

**Definition 10.3.** The Hall algebra \(\mathcal{H}(\mathcal{A})\) associated to \(\mathcal{A}\) is generated as a vector space by isomorphism classes of objects in \(\mathcal{A}\) and has multiplication given by

\[
[X] \cdot [Y] = \sum_{[Z]} g_{X,Y}^Z [Z]
\]

where the Hall numbers are

\[
g_{X,Y}^Z = \frac{|\{0 \to X \to Z \to Y \to 0\}|}{|\text{Aut}(X)||\text{Aut}(Y)|}.
\]

As a motivating example, let \(\mathfrak{g}\) be a Lie algebra of type \(A, D,\) or \(E\). It has an associated Dynkin diagram, for example \(A_3\), which looks like \(\bullet - \bullet - \bullet\). Take a quiver \(Q\) on this diagram, for example \(\bullet \to \bullet - \bullet\). Let \(\mathcal{A} = \text{Rep}(Q)\), the category of \(\mathbb{F}_q\)-representations of \(Q\) for some finite field \(\mathbb{F}_q\). We get an associated Hall algebra \(\mathcal{H}(\text{Rep}(Q))\).

However, associated to \(\mathfrak{g}\) we also have the quantum enveloping algebra

\[
U_q(\mathfrak{g}) = U_q(\mathfrak{n}^+) \otimes U_q(\mathfrak{h}) \otimes U_q(\mathfrak{n}^-).
\]

We write \(U_q(\mathfrak{b}) = U_q(\mathfrak{n}^+) \otimes U_q(\mathfrak{n}^-)\). Ringel proved that \(U_q(\mathfrak{b})\) is closely related to \(\mathcal{H}(\text{Rep}(Q))\). A natural question is therefore whether there is an algebra arising
from $A$ corresponding to $U_q(g)$ in this same way. The conjecture is that the “right” algebra is obtained from the root category $D^b(A)/T^2$, where $D^b(A)$ is the bounded derived category, which is a triangulated category, and $T$ is its shift functor [59].

An immediate problem in attempting to find such an algebra is that the root category is triangulated rather than abelian. Thus, the question becomes how to get a “Hall algebra” from a triangulated category. Toën has developed an approach as follows.

Let $Ch(F_q)$ be the category of chain complexes over $F_q$. Let $T$ be a small dg category over $F_q$ (or category enriched over $Ch(F_q)$) such that for any objects $x$ and $y$ of $T$, the complex $T(x,y)$ is cohomologically bounded and has finite-dimensional cohomology groups. Define $\mathcal{M}(T)$ to be the category of $T^{op}$-modules, or dg functors $T \to Ch(F_q)$. This category has a model structure given by levelwise weak equivalences and fibrations, and furthermore its homotopy category $Ho(\mathcal{M}(T))$ is triangulated. There is also a model category $\mathcal{M}(T)^[1]$ whose objects are the morphisms in $\mathcal{M}(T)$.

We have a diagram of left Quillen functors

$$
\xymatrix{
\mathcal{M}(T)^[1] \ar[r]^t \ar[d]^{s \times c} & \mathcal{M}(T) \\
\mathcal{M}(T) \times \mathcal{M}(T)
}
$$

where $s$ is the source map, $t$ is the target map, and $c$ is the cone map, given by $c(x \to y) = y \amalg_x 0$, where $0$ is the zero object of $\mathcal{M}(T)$.

Let $\mathcal{P}(T)$ be the full subcategory of $\mathcal{M}(T)$ of perfect objects, which in this case consists of the dg functors whose images in $Ch(F_q)$ are cohomologically bounded with finite-dimensional cohomology groups. We restrict the above diagram to subcategories of weak equivalences between perfect and cofibrant objects:

$$
\xymatrix{
w(\mathcal{P}(T)^[1])^{cof} \ar[r]^t \ar[d]^{s \times c} & w\mathcal{P}(T)^{cof} \\
w\mathcal{P}(T)^{cof} \times w\mathcal{P}(T)^{cof}
}
$$

We apply the nerve functor to this diagram and denote it as follows:

$$
\xymatrix{X^{(1)} \ar[r]^t \ar[d]^{s \times c} & X^{(0)} \\
X^{(0)} \times X^{(0)}
}
$$

Define the derived Hall algebra $DH(T)$ as a vector space by $\mathbb{Q}_c(X^{(0)})$, the finitely supported functions $\pi_0(X^{(0)}) \to \mathbb{Q}$, and define the multiplication $\mu = t_! \circ (s \times c)^*$. While $(s \times c)^*$ is the usual pullback, $t_!$ is a more complicated push-forward.

**Theorem 10.4.** [69]

1. $DH(T)$ is an associative, unital algebra.
The multiplication is given by $[x] \cdot [y] = \sum_{[z]} g_{x,y}^z [z]$, where the derived Hall numbers are

$$g_{x,y}^z = \frac{[x,z][y]}{|Aut(x)| \prod_{i > 0} |[x,x[i]]| (-1)^i}$$

where brackets denote maps the homotopy category and $[x,z]_y$ denotes the maps $x \to z$ with cone $y$.

(3) The algebra $\mathcal{D}H(T)$ depends only on $Ho(\mathcal{M}(T))$.

The homotopy fiber product of model categories is the key tool in the proof that the derived Hall algebra is associative.

**Theorem 10.5.** [18] Toën’s derived Hall algebra construction can be given for a suitably finitary stable complete Segal space.

By “stable” here we mean that the homotopy category is triangulated. Xiao and Xu prove that his formula (2) holds for any finitary triangulated category, but the additional homotopy-theoretic information may be useful. Unfortunately, in either case, the root category is not “finitary” so we cannot yet find a derived Hall algebra associated to it.

11. **Commutative algebra for quasi-categories**

(Two talks given by Vladimir Hinich, plus some additional notes)

Let $k$ be a field of characteristic zero and $A$ an associative algebra over $k$. Let $P$ be the free bimodule resolution of $A$,

$$\cdots \xrightarrow{d} A \otimes A \otimes A \xrightarrow{d} A \otimes A \xrightarrow{d} A \rightarrow 0$$

where

$$d(a_1 \otimes \cdots \otimes a_n) = \sum_i a_1 \otimes \cdots \otimes a_i a_{i+1} \otimes \cdots \otimes a_n.$$

We define

$$\text{Hoch}^n(A) = \text{Hom}_{A \otimes A^{op}}(P, A).$$

In other words,

$$\text{Hoch}^n(A) = \text{Hom}(A^{\otimes n}, A)$$

for all $n \geq 0$. The differential

$$d: \text{Hoch}^n(A) \to \text{Hoch}^{n+1}(A)$$

is given by the formula

$$(df)(a_1, \ldots, a_{n+1}) = a_1 f(a_2, \ldots, a_{n+1})$$

$$= \sum_{i=1}^n (-1)^i f(a_1, \ldots, a_i a_{i+1}, \ldots, a_{n+1}) - (-1)^n f(a_1, \ldots, a_n) a_{n+1}$$

for $f \in \text{Hom}(A^{\otimes n}, A)$. The cohomology of this complex is $HH^*(A)$, the Hochschild cohomology of $A$.

In 1963, Gerstenhaber proved that $HH^*(A)$ is commutative and $HH^*(A)[1]$ is a Lie algebra. The two structures are compatible in the sense that an analogue of the Leibniz rule holds. This structure is called a Gerstenhaber algebra and is given by a Gerstenhaber operad $e_2$. In the 1970s, F. Cohen considered the little
cubes operad $\mathcal{E}(2)$ and showed that $H_\ast(\mathcal{E}(2)) = e_2$. In other words, for each $n$, $H_\ast(\mathcal{E}(2)(n)) = e_2(n)$.

In 1993, Deligne asked whether this isomorphism could be lifted to an action of the $\mathcal{E}(2)$-operad on $\text{Hoch}^\ast(A, A)$. This conjecture was proved in the late 1990s by many different people. The idea of the proof, as developed by Lurie in [52], is as follows.

1. The little cubes operad $\mathcal{E}(2)$ acts on a double loop space $\Omega^2(X)$.
2. Let $\mathcal{C}$ be some kind of higher category and $X$ an object of $\mathcal{C}$. Then $\text{End}(X)$ is an associative algebra (for a category) and $\text{End}(id_X)$ is a double loop space.
3. Look at the category with objects associative algebras over $k$ and, for any such algebras $A$ and $B$, $\text{Map}(A, B)$ is the category of $A - B$-bimodules, with composition given by

   $$(AM_{B, B} N_C) \mapsto M \otimes B.$$ 

   The identity map is given by the bimodule $AA$. The endomorphisms of the identity map should be described by $R\text{Hom}_{A \otimes A^{op}}(A, A) = \text{Hoch}^\ast(A)$.

However, Lurie does not specify what the “higher category” is; it is not an $(\infty, 1)$-category.

These steps given a “moral explanation” for the Deligne Conjecture. They acquire a precise sense in the setup of quasi-categories, and this talk is based on excerpts from two of Lurie’s papers [51], [52]. In what follows, we use quasi-categorical versions of symmetric monoidal categories and of operads. To go further into this proof, we need to understand quasi-operads and symmetric monoidal categories.

The notion of symmetric monoidal category is not very simple, even in the classical setup because of the necessity of describing the axioms of associativity $((x \otimes y) \otimes z \cong x \otimes (y \otimes z))$ and commutativity $(x \otimes y \cong y \otimes x)$. Therefore, we start our discussion presenting a further version of the definition which itself takes care of these constraints. This definition will be further generalized to the world of quasi-categories.

Back in the world of sets, recall the definition of a colored operad $\mathcal{O}$. It has a collection of colors $[\mathcal{O}]$, together with $a: I \to [\mathcal{O}]$ for a finite set $I$ (the multiple inputs) and $b \in [\mathcal{O}]$ (the one output). Then $\mathcal{O}(a, b)$ is a set, and composition is given by

$$\mathcal{O}(b, c) \times \prod_{j \in J} \mathcal{O}(a|_{\varphi^{-1}(j)}, b(j)) \to \mathcal{O}(a, c)$$

where we have the diagram

```
  I --a--> [\mathcal{O}]
   |          ^
   |          |
   v          v
  j --b--> c
```

satisfying associativity.

A useful exercise is to check that this definition includes the action of the symmetric groups automatically, where possible, as well as equivariance of composition. The same kind of definition works for topological operads; in this case $\mathcal{O}(a, b)$ is a topological space.

Another name for colored operads is that of pseudo-tensor categories, due to the fact that the unary operations $\mathcal{O}(a, b)$ with $|I| = 1$ endow $\mathcal{O}$ with the structure
of a category, whereas the other operations, if representable, define a symmetric monoidal structure.

A colored operad $O$ has an associated category $O_1$ with objects $[O]$ and $O_1(a, b) = O(a, b)$. Notice that a category is a special case of a colored operad, where we have only unary operations.

For any function $a: I \to [O]$, we have a functor $O_1 \to \text{Sets}$ given by $b \mapsto O(a, b)$. We assume that all these functors are representable and choose the representing object $\otimes^I a$, defined up to unique isomorphism. It contains precisely the data of a symmetric monoidal category.

**Definition 11.1.** A symmetric monoidal category is a colored operad for which all functors above are representable.

**Example 11.2.** The terminal operad in $\text{Sets}$ is given by $O(a, b) = \ast$.

It is convenient to reformulate the notion of colored operad, as well as that of a symmetric monoidal category, so that all compositions, not just the unary operations, are part of a category structure. This process can be done as follows.

Let $O$ be a colored operad, and let $\Gamma$ be the category of finite pointed sets $[67]$. Define a category $O \otimes \Gamma$, together with a functor $O \otimes \Gamma \to \Gamma$, with

$$\text{ob}(O \otimes \Gamma) = \{a: I \to [O]\}$$

and

$$\text{Hom}_{O \otimes \Gamma}(a, b) = \prod_{\varphi: I_\ast \to J_\ast} \prod_j O(a|_{\varphi^{-1}(j)}, b(j)).$$

Here $I_\ast = I \amalg \{\ast\}$ are the objects of $\Gamma$ and $\varphi: I_\ast \to J_\ast$ is a map from $I$ to $J$. Let $\langle n \rangle = \{1, \ldots, n\}_\ast$ and notice that $O_{(n)}^{\otimes} = (O_{(1)^n})^{\otimes}$. The map $O^{\otimes} \to \Gamma$ satisfies some properties, which will be written down precisely below in the context of quasi-categories.

**Definition 11.3.** $[53]$ A map $\varphi: \langle m \rangle \to \langle n \rangle$ is inert if for every $i = 1, \ldots, n$, $|\varphi^{-1}(i)| = 1$. It is semi-inert if $|\varphi^{-1}(i)| < 1$ for each $i$.

**Definition 11.4.** $[53]$ Let $p: C \to D$ be a map of quasi-categories, and $\alpha: c \to \alpha'$ a morphism in $C$. Then $\alpha$ is $p$-cocartesian if the diagram

$$\begin{array}{ccc}
\text{Map}_C(c', c'') & \longrightarrow & \text{Map}_C(c, c'') \\
\downarrow & & \downarrow \\
\text{Map}_D(pc', pc'') & \longrightarrow & \text{Map}_D(pc, pc'')
\end{array}$$

is homotopy cartesian.

Note that the horizontal arrows are not canonically defined; however, the definition can be made precise.

**Definition 11.5.** Let $O^{\otimes}$ be a quasi-category. A map $p: O^{\otimes} \to N(\Gamma)$ is a quasi-operad if:

1. For any inert $\varphi: \langle m \rangle \to \langle n \rangle$ and any $x \in O_{(m)}^{\otimes}$, there exists $\tilde{\varphi}: x \to y$ over $\varphi$ which is $p$-cocartesian; alternatively, for any $\varphi$ in $N(G)_1$, there is a lifting (or cocartesian fibration) $\varphi_1: O_{(m)}^{\otimes} \to O_{(n)}^{\otimes}$. (In other words, for any arrow in $N(\Gamma)$ whose source lifts, the arrow can be lifted to a $p$-cocartesian arrow.)
(2) If $\rho_i: \langle n \rangle \to \langle 1 \rangle$ is an inert map with $\rho_i(i) = 1$, then
\[
\prod_i (\rho_i)_! : \mathcal{O}^\otimes_{\langle n \rangle} \to \prod_i \mathcal{O}^\otimes_{\langle 1 \rangle}
\]
is a categorical equivalence.

(3) For every $\varphi: \langle m \rangle \to \langle n \rangle$, $c \in \mathcal{O}^\otimes_{\langle m \rangle}$, and $c' \in \mathcal{O}^\otimes_{\langle n \rangle}$, there is an equivalence of maps in the fiber
\[
\text{Map}^\varphi(c, c') \to \prod_i \text{Map}^{\rho_i(\varphi)}(c_i, (\rho_i)_!(c'_i)).
\]

**Example 11.6.** If $\mathcal{O}$ is a topological operad, then $\text{Sing}(\mathcal{O})$ is an operad in $\mathcal{S}ets$ (actually in Kan complexes). Then we get a simplicial category $\text{Sing}(\mathcal{O})^\otimes$ and get a quasi-operad $N^\Delta(\text{Sing}(\mathcal{O})^\otimes) \to \text{nerve}(\Gamma)$.

**Example 11.7.** Let $\tilde{\mathcal{O}}$ be a topological colored operad. We can describe it by a functor of topological categories $\tilde{\mathcal{O}}^\otimes \to \Gamma$. Passing to singular simplices and to the nerve, we get a map $p: \mathcal{O}^\otimes \to \text{nerve}(\Gamma)$ of quasi-categories. Thus, any topological operad gives rise to a quasi-operad. In particular, all operads in $\mathcal{S}ets$ give rise to quasi-operads.

**Example 11.8.**

1. For the commutative operad $\text{Com}$, we get
   \[
   \text{Com}^\otimes = \text{nerve}(\Gamma) \to \text{nerve}(\Gamma),
   \]
   the identity map.

2. For the associative operad $\text{Assoc}$, we get $\text{ob}(\text{Assoc}^\otimes) = \text{ob}(\Gamma)$ and
   \[
   \text{Hom}_{\text{Assoc}^\otimes}(\langle m \rangle, \langle n \rangle) = \{(\varphi: \langle m \rangle \to \langle n \rangle, \leq)\}
   \]
   where the maps $\varphi$ are in $\Gamma$ and $\leq$ denotes a total order on all preimages. Alternatively, we could write this set as the collection of all pairs $(\varphi, \omega)$ where $\varphi$ is a morphism of $\Gamma$ and $\omega$ is a collection of total orders on $\varphi^{-1}(j)$ for each $j = 1, \ldots, n$. We will denote the corresponding operad
   \[
   p: \text{Assoc}^\otimes \to \text{nerve}(\Gamma).
   \]

3. We can take the trivial operad $\text{Triv}$, and then $\text{Triv}^\otimes \subseteq \text{nerve}(\Gamma)$ consists of the inert arrows.

4. The sub-quasi-category of semi-inert arrows gives $\mathcal{E}[0]$, whose algebras are pointed objects. (Classically, $\mathcal{E}[0]$-algebras are spaces with a marked point.)

5. More generally, $\mathcal{E}[k]$ comes from the topological operad $\mathcal{E}(k)$ of little $k$-cubes. It has objects $\langle \langle n \rangle \rangle$.

**Definition 11.9.** A symmetric monoidal quasi-category is a quasi-operad $p: \mathcal{C}^\otimes \to \text{nerve}(\Gamma)$ such that $p$ is a cocartesian fibration.

We now look again at the motivating problem. The Gerstenhaber operad appears in topology as the homology of a certain topological operad (the small cubes operad) in dimension 2.

**Definition 11.10.** Fix $k = 0, 1, \ldots$ and let $\Box^k$ be the standard $k$-cube. Define $\mathcal{E}[k](n) = \text{Rect}(\Box^k \times \{1, \ldots, n\}, \Box^k)$, the space of rectilinear embeddings. The latter means that the images of different copies of $\Box^k$ have no intersection, and each $\Box^k \to \Box^k$ is the product of rectilinear maps in each coordinate. The collection
\[
\{\mathcal{E}[k](n) \mid n \geq 0\}
\]
forms an operad in $\text{Top}$, the small $k$-cubes operad.
Theorem 11.11. Gerst(n) = \( H_*(\mathcal{E}[k](n)) \).

Now the following result seems very natural.

Theorem 11.12 (Deligne Conjecture). There is a natural \( \mathcal{E}[2] \)-algebra structure on \( \text{Hoch}^*(A) \).

This conjecture has been proved in different formulations by different authors around the ’90s, but there is still a feeling that there is no full understanding of what is going on.

To understand the problem more fully, we investigate tensor products of operads. Let \( \mathcal{O}_1 \) and \( \mathcal{O}_2 \) be (conventional) topological operads. Maps \( a: X^I \to X \) and \( b: X^J \to X \) commute if the diagram

\[
\begin{array}{ccc}
X^I \times J & \xrightarrow{b^I} & X^I \\
\downarrow a^I & & \downarrow \\
X^J & \xrightarrow{\text{commutes}} & X
\end{array}
\]

commutes.

Definition 11.13. An \( (\mathcal{O}_1, \mathcal{O}_2) \)-algebra is a topological space with commuting structures of \( \mathcal{O}_1 \)- and \( \mathcal{O}_2 \)-algebras.

May claimed in the ’80s that such a pair of commuting structures is given by a canonically-defined structure of an algebra over a new operad \( \mathcal{O}_1 \otimes^M \mathcal{O}_2 \), the May tensor product.

It is convenient to present quasi-operads as fibrant objects in a certain simplicial model category. We first describe the objects of the underlying category.

Definition 11.14. [51] A marked simplicial set is a pair \( (X, \Sigma) \) where \( X \) is a simplicial set and \( \Sigma \) is a collection of edges containing the degenerate ones.

Definition 11.15. [51] A preoperad is a map of marked simplicial sets \( p: (X, \Sigma) \to \text{nerve}(\Gamma) \) where each \( X \) is an \( \infty \)-operad and \( \Sigma \) is the class of inert arrows.

Theorem 11.16. [51] The category of preoperads admits a simplicial model category structure for which:

1. the simplicial structure is defined as in \( \text{SSets}_* \),
2. cofibrations are the injective maps, and
3. weak equivalences are those giving rise to homotopy equivalences of simplicial homs into each preoperad \( p: (X, \Sigma) \to \text{nerve}(\Gamma) \) where each \( X \) is an \( \infty \)-operad and \( \Sigma \) is the class of inert arrows.

For \( p: \mathcal{O}^\otimes \to N(\Gamma) \), denote by \( \mathcal{O}^{\otimes;\natural} \) the preoperad \( (X, \Sigma) \) with \( \Sigma \) the inert arrows.

Let \( K_\# = (K, K_1) \) be the maximal pair and \( K^\flat = (K, s_0(K_0)) \) be the minimal pair. If \( \mathcal{X} = (X, \mathcal{E}) \), then

\[
\text{Hom}(K, \text{Map}^{\#}(\mathcal{X}, \mathcal{Y})) = \text{Hom}_{N(\Gamma)}(\mathcal{X} \times K^\#, \mathcal{Y})
\]

which is a Kan complex, and

\[
\text{Hom}(K, \text{Map}^{\natural}(\mathcal{X}, \mathcal{Y})) = \text{Hom}_{N(\Gamma)}(\mathcal{X} \times K^\flat, \mathcal{Y})
\]
which is a quasi-category in good cases. The cofibrations are injections, and fibrant objects are the marked simplicial sets \((X, E)\) where \(X\) is a quasi-operad and \(E\) consists of the cocartesian lifts of inert maps. A map \(f: X \to Y\) is a weak equivalence if for any \(O\) fibrant, \(\text{Map}^\#(Y, O) \to \text{Map}^\#(X, O)\) is a weak equivalence.

Let \(\overline{X}\) and \(\overline{Y}\) be preoperads, and consider the join \(\wedge: \text{nerve}(\Gamma) \times \text{nerve}(\Gamma) \to \text{nerve}(\Gamma)\), defined by \(((I, i), (J, j)) \mapsto (I \times J)/((i \times J) \amalg (I \times j))\). Write \(\overline{X} \odot \overline{Y}\) for the composite

\[
\overline{X} \times \overline{Y} \to \text{nerve}(\Gamma) \times \text{nerve}(\Gamma) \to \text{nerve}(\Gamma).
\]

If \((X, \Sigma)\) and \((X', \Sigma')\) are operads (fibrant preoperads), the product \((X, \Sigma) \odot (X', \Sigma')\) is not usually fibrant. We can use fibrant replacement to define Lurie’s tensor product.

**Definition 11.17.** If \(O\) and \((O')^\otimes\) are operads, then \(O^\otimes \odot^L (O')^\otimes\) is a fibrant replacement of \((O \odot O')^\otimes\).

Thus, we have the following.

**Definition 11.18.** Let \(O^\otimes\), \(O'^\otimes\), and \(O''^\otimes\) be quasi-operads. A diagram

\[
\begin{array}{ccc}
O^\otimes & \longrightarrow & O^\otimes \\
\downarrow & & \downarrow \\
\text{nerve}(\Gamma) \times \text{nerve}(\Gamma) & \longrightarrow & \text{nerve}(\Gamma)
\end{array}
\]

exhibits \(O^\otimes\) as a tensor product of \(O'^\otimes\) and \(O''^\otimes\) if the induced map

\[
O'^\otimes \odot O''^\otimes \to O^\otimes
\]

is a weak equivalence of preoperads, i.e., if for every quasi-operad \(C^\otimes\),

\[
\text{Map}^\#(O^\otimes, C^\otimes) \to \text{Map}^\#(O'^\otimes \odot O''^\otimes, C^\otimes)
\]

is a homotopy equivalence.

For a topological operad, there is a map \(O \otimes^L O' \to O \otimes^M O'\).

**Definition 11.19.** Suppose that \(C\) and \(O\) are operads. An \(O\)-algebra in \(C\) is a section \(A: O \to C\), i.e.,

\[
\begin{array}{ccc}
O^\otimes & \longrightarrow & C^\otimes \\
\downarrow & & \downarrow \\
\text{nerve}(\Gamma) & & 
\end{array}
\]

such that inert maps go to inert maps.

Denote by \(\text{Alg}_O(C)\) the category of \(O\)-algebras in \(C\).

**Definition 11.20.** The quasi-category \(\text{Alg}_O(C)^\otimes\) represents the functor \(\text{PreOp} \to \text{Kan}\) given by \(Y \mapsto \text{Hom}^\#_{\text{PreOp}}(Y \otimes O^\otimes, C^\otimes)\), where if \(O^\otimes\) is an operad, then \(O^\otimes\) is a preoperad with \(\mathcal{E}\) consisting of the inert maps.

A map of quasi-operads is a map preserving inert arrows. A fibration is a map which is a (categorical) fibration.

**Definition 11.21.** Let \(p: C \to O\) be a fibration of operads and \(u: O' \to O\) a morphism of operads. An \(O\)-algebra object in \(C\) is the \(O'\)-algebra object in \(O' \times_O C\), i.e., a map of operads \(A: O' \to C\) such that \(p \circ A = u\).
Example 11.22. In conventional category theory, any category $\mathcal{C}$ defines an operad (with no $n$-ary operations for $n \neq 1$). An algebra over such an operad, say in $\mathcal{T}op$, is just a functor $\mathcal{C} \to \mathcal{T}op$.

Example 11.23. The quasi-categorical version of the above example is as follows. Let $\text{Triv}$ be the trivial operad. A map $\text{Triv} \to \text{nerve}(\Gamma)$ is an injection, so any operad $\mathcal{O}^\otimes \to \text{nerve}(\Gamma)$ admits at most one morphism to $\text{Triv}$. Existence of such a morphism means that all arrows in $\mathcal{O}^\otimes$ are inert. A morphism $\mathcal{O}^\otimes \to \mathcal{T}op$ restricts to a map $\mathcal{O}^\otimes_{(1)} \to \mathcal{T}op$. Also, the map $\text{Fun}^{lax}(\mathcal{O}^\otimes, \mathcal{T}op^\otimes) \to \text{Fun}(\mathcal{O}^\otimes_{(1)}, \mathcal{T}op)$ is an acyclic fibration.

Example 11.24. Let $\mathcal{O} = \text{nerve}(\Gamma)$ and $\mathcal{C} = \mathcal{T}op^\otimes$. A map $\mathcal{O} \to \mathcal{C}$ assigns to $\langle n \rangle$ a collection of $n$ topological spaces (all homotopy equivalent to each other). The arrow $\langle 2 \rangle \to \langle 1 \rangle$ carrying $1, 2 \mapsto 1$ defines an operation which is commutative up to homotopy. Thus, our notion of $\mathcal{O}$-algebra is automatically the “up-to-homotopy” notion.

Example 11.25. Given a topological operad $\tilde{\mathcal{O}}$, define the corresponding quasi-operad $\mathcal{O}^\otimes$. It is an easy exercise to assign to any $\mathcal{O}^\otimes$-algebra a morphism of operads $\mathcal{O}^\otimes \to \mathcal{T}op^\otimes$ and therefore an $\mathcal{O}^\otimes$-algebra in the sense of our definition.

The quasi-category $\text{Alg}_{\mathcal{O}}(\mathcal{C})$ of $\mathcal{O}$-algebras in an operad $\mathcal{C}$ has a canonical operad structure: the functor $\mathcal{O}pY \to \text{Hom}_{\mathcal{O}p}(Y \otimes \mathcal{O}^\otimes_\Delta, \mathcal{C}^\otimes_\Delta)$ is representable by an operad which we denote $\text{Alg}_{\mathcal{O}}(\mathcal{C})^\otimes$; it is even a symmetric monoidal quasi-category if $\mathcal{C}$ is. The fiber of $\text{Alg}_{\mathcal{O}}(\mathcal{C})^\otimes$ at $\langle 1 \rangle$ is precisely $\text{Alg}_{\mathcal{O}}(\mathcal{C})$.

Now we can define $\text{Alg}_{\mathcal{O}_1}(\text{Alg}_{\mathcal{O}_2}(\mathcal{C}))$ and compare it to $\text{Alg}_{\mathcal{O}_1 \otimes \mathcal{O}_2}(\mathcal{C})$:

$$
\text{Hom}_{\mathcal{O}p}(Y, \text{Alg}_{\mathcal{O}_1}(\text{Alg}_{\mathcal{O}_2}(\mathcal{C}))) = \text{Hom}_{\mathcal{O}p}(Y \otimes \mathcal{O}^\otimes_1, \text{Alg}_{\mathcal{O}_2}(\mathcal{C})^\otimes) = \text{Hom}_{\mathcal{O}p}(Y \otimes \mathcal{O}^\otimes_1 \otimes \mathcal{O}^\otimes_2, \mathcal{C}^\otimes) = \text{Hom}_{\mathcal{O}p}(Y, \text{Alg}_{\mathcal{O}_1 \otimes \mathcal{O}_2}(\mathcal{C})).
$$

Given two topological operads $\tilde{\mathcal{O}}_1$ and $\tilde{\mathcal{O}}_2$, we have a map

$$
\mathcal{O}_1 \otimes^L \mathcal{O}_2 \to \mathcal{O}_1 \otimes^M \mathcal{O}_2
$$

which need not be an equivalence in general. For instance, $\mathcal{Assoc}^M \mathcal{Assoc} = \mathcal{Com}$. However, we believe that this is an equivalence if $\tilde{\mathcal{O}}_1$ and $\tilde{\mathcal{O}}_2$ are cofibrant.

The quasi-operads $\mathcal{E}[k]$ are defined as the ones constructed from the topological operads $\mathcal{E}[k]$. The map $\mathcal{E}[k] \to N(\Gamma)$ is bijective on objects; the map

$$
\text{Map}_{\mathcal{E}[k]}(\langle m \rangle, \langle n \rangle) \to \text{Map}_{N(\Gamma)}(\langle m \rangle, \langle n \rangle)
$$

is $(k - 1)$-connective.

Example 11.26. Let $\mathcal{C}^\otimes$ be a symmetric monoidal quasi-category. The arrow $\varphi : \langle 0 \rangle \to \langle 1 \rangle$ gives $\varphi_1 : \mathcal{C}^\otimes_{\langle 0 \rangle} \to \mathcal{C}^\otimes_{\langle 1 \rangle}$. Since $\mathcal{C}^\otimes, \langle 0 \rangle$ is contractible, this defines an object 1 in $\mathcal{C}^\otimes_{\langle 1 \rangle}$, uniquely up to equivalence. An $\mathcal{E}[0]$-algebra $A$ in $\mathcal{C}^\otimes$ defines in particular a map $1 \to A$ in $\mathcal{C}^\otimes_{\langle 1 \rangle}$. The claim is that

$$
\text{Fun}^{lax}(\mathcal{E}[0], \mathcal{C}^\otimes) \to \mathcal{C}^\otimes_{\langle 1 \rangle}
$$

is an acyclic fibration. In other words, an $\mathcal{E}[0]$-algebra is uniquely given, up to equivalence, by a pointed object in $\mathcal{C}^\otimes_{\langle 1 \rangle}$. 
Assume that $\mathcal{C} \to \text{nerve}(\Gamma)$ is a symmetric monoidal quasi-category such that $\text{Map}_{\mathcal{C} \otimes} (x, y)$ are all $(n - 1)$-truncated (have no higher homotopy groups). Then we claim that $\text{Alg}_{\text{Com}}(\mathcal{C}) \to \text{Alg}_{\mathcal{E}[k]}(\mathcal{C})$ is an equivalence for $k > n$.

Example 11.27. An $\mathcal{E}[2]$-algebra in $\mathcal{S}ets$ is already a commutative monoid. An $\mathcal{E}[1]$-algebra in $\mathcal{C}at$ is a monoidal category; an $\mathcal{E}[2]$-algebra in $\mathcal{C}at$ is a braided monoidal category; an $\mathcal{E}[3]$-algebra in $\mathcal{C}at$ is a symmetric monoidal category.

Define a map $\mathcal{E}[m] \times \mathcal{E}[n] \to \mathcal{E}[m+n]$ which assigns to a pair $\alpha: \Box^m \times I \to \Box^m$, $\beta: \Box^n \times J \to \Box^n$. The product map $\alpha \otimes \beta$ is $\Box^{m+n} \times I \times J \to \Box^{m+n}$.

Theorem 11.28. (Dunn, '88) The above described map induces and equivalence $\mathcal{E}[m] \otimes \mathcal{E}[n] \to \mathcal{E}[m+n]$.

We assume the similar result for quasi-operads $\mathcal{E}[n]$ can be deduced from Dunn’s theorem, since $\mathcal{E}[k]$ are cofibrant. Lurie gives an independent proof [52].

What is the correct definition of the center of an associative algebra? Here, “correct” means “categorical” with the hope of generalization to higher categories.

Definition 11.29. Let $A$ be an associative algebra with unit. Its center is a universal object in the category of diagrams

\[ \begin{array}{ccc}
A \otimes Z & \xrightarrow{id \otimes 1} & A \\
\downarrow & & \downarrow \text{id} \\
A & \xrightarrow{id} & A.
\end{array} \]

We are going to give a quasi-categorical analogue for this construction, fit for $\mathcal{E}[k]$-algebras. The center will automatically have the extra structure of an $\mathcal{E}[1]$-algebra commuting with the original structure. Together with the additivity theorem and the identification of the center with the Hochschild complex, in the case $k = 1$, gives the Deligne Conjecture.

12. Models for $(\infty, n)$-categories

An $(\infty, n)$-category is a generalization of an $(\infty, 1)$-category, where now $k$-morphisms are invertible for $k > n$. The heuristic idea is that an $(\infty, n)$-category should be modeled by a category enriched in $(\infty, n - 1)$-categories.

In fact, we have already used that one model for $(\infty, 1)$-categories is that of simplicial categories, or categories enriched in simplicial sets, and simplicial sets can be regarded as $(\infty, 0)$-categories, which are just $\infty$-groupoids. If we want to generalize, we first need to have a closed monoidal category, so that composition makes sense. If we want to do so in such a way that we get a model structure, we need at the very least that our model form a closed monoidal model category. While simplicial categories do form a monoidal category under cartesian product, this structure is not in fact compatible with the model structure and therefore we cannot blindly proceed be induction.

Since quasi-categories form a monoidal model category with internal hom objects, we can enrich over them and obtain a model for $(\infty, 2)$-categories. Similarly, we could take categories enriched in complete Segal spaces. However, we will have the same problems as before if we then try to enrich over these enriched categories to continue the induction.
Other models for \((\infty, n)\)-categories generalize some of our other approaches to \((\infty, 1)\)-categories. Because Segal categories and complete Segal spaces are simplicial objects, we can generalize them by considering multi-simplicial objects. We first look at the \(n\)-fold complete Segal spaces of Barwick and Lurie.

We begin with \(n\)-fold simplicial spaces, or functors \(\Delta^{op} \to \text{SSets}^n\), which can equivalently be regarded as functors \(\Delta^{op} \to \text{SSets}^{(\Delta^p)^{n-1}}\). An \(n\)-fold simplicial space is essentially constant if there exists a levelwise weak equivalence \(X' \to X\) where \(X'\) is constant.

**Definition 12.1.** An \(n\)-fold simplicial space \(X : \Delta^{op} \to \text{SSets}^n\) is an \(n\)-fold Segal space if:

1. each \(X_m\) is an \(n-1\)-fold Segal space,
2. \(X_m \to X_1 \times X_0 \cdots \times X_0 X_1\) is a weak equivalence of \(n-1\)-fold Segal spaces,
3. \(X_0\) is essentially constant.

**Definition 12.2.** An \(n\)-fold complete Segal space is an \(n\)-fold Segal space such that:

1. each \(X_m\) is a complete Segal space, and
2. the simplicial space \(X_{m,0,...,0}\) is a complete Segal space.

Similarly, one can define Segal \(n\)-categories as given by Hirschowitz-Simpson and Pelissier, which are \(n\)-fold simplicial spaces with such a Segal condition but with various discreteness conditions replacing the completeness conditions.

While 1-fold complete Segal spaces are just complete Segal spaces, the nice property that the model structure \(\mathcal{CSS}\) is cartesian does not seem to be retained. With the goal of finding a model which was still cartesian, Rezk developed his \(\Theta_n\)-spaces.

We first need to give an inductive definition of the category \(\Theta_n\). Let \(\Theta_0\) be the terminal category with one object and no non-identity morphisms. Then inductively define \(\Theta_n\) to have objects \(\lfloor m \rfloor (c_1, \ldots, c_m)\) where \(\lfloor m \rfloor\) is an object of \(\Delta\) and \(c_1, \ldots, c_m\) are objects of \(\Theta_{n-1}\). One can think of these objects as strings of labeled arrows

\[
\begin{array}{ccccccccc}
0 & \rightarrow & c_1 & \rightarrow & c_2 & \rightarrow & c_3 & \rightarrow & \cdots & \rightarrow & c_{m-1} & \rightarrow & c_m & \rightarrow & m.
\end{array}
\]

Morphisms

\[
\lfloor m \rfloor (c_1, \ldots, c_m) \rightarrow \lfloor p \rfloor (d_1, \ldots, d_p)
\]

are given by \((\delta, \{f_{ij}\})\) where \(\delta : \lfloor m \rfloor \rightarrow \lfloor p \rfloor\) is a morphism of \(\Delta\) and \(f_{ij} : c_i \rightarrow d_j\) is a morphism in \(\Theta_{n-1}\), defined whenever \(\delta(i-1) < j \leq \delta(i)\). For example, if we take \(\delta : [3] \rightarrow [4]\) defined by \(0,1 \mapsto 1, 2 \mapsto 3,\) and \(3 \mapsto 4\), then we would have \((\delta, f_{22}, f_{23}, f_{31}) : [3](c_1, c_2, c_3) \rightarrow [4](d_1, d_2, d_3, d_4)\). Notice in particular that \(\Theta_1 = \Delta\).

The idea here is that objects of \(\Theta_n\) are “basic” strict \(n\)-categories in the same way that objects of \(\Delta\) are “basic” categories. If we consider functors \(\Theta_n^{op} \to \text{SSets}\), then there are “Segal maps” giving composition in multiple levels, and we want to look at Segal space objects for which these maps are weak equivalences. While it is more difficult to explain, there is also a notion of “completeness” for such functors, giving a definition of complete Segal objects.
Theorem 12.3. [63] There is a cartesian model category $\Theta_n Sp$ on the category of functors $\Theta_n^{op} \to \mathcal{SSets}$ in which the fibrant objects are the complete Segal objects.

Now, we can enrich over this structure, using a result of Lurie [53].

Theorem 12.4. (B-Rezk) There is a model structure on the category of small categories enriched over $\Theta_{n-1} Sp$, with weak equivalences analogues of Dwyer-Kan equivalences.

13. Finite approximations to $(\infty, 1)$-categories/homotopy theories

(Talk given by David Blanc, plus some additional notes)

In [36], Dwyer and Kan proposed weak equivalence classes of simplicially enriched categories as their candidate for a “homotopy theory” in Quillen’s sense [61, I, §2]: that is, a context for encoding all homotopy invariants of any given model category $\mathcal{C}$ (and no more). This is a point of view, rather than a precise statement, mainly because we have no good definition of “all homotopy invariants” of a model category. Nevertheless, homotopy theories in this sense seem to be the best approximation available.

However, the model category $\mathcal{S}Cat$ and all its Quillen equivalent versions share the difficulty that they are hard to work and compute with. For practical purposes, we therefore need smaller versions, obtained either by limiting the objects or making the hom-complexes simpler. The way to do the latter is to take $n$-Postnikov approximations, which is a monoidal functor in $\mathcal{S}Sets$ and so extends to $\mathcal{S}Cat$. We can then try to produce alternative models for $(n, 1)$-categories.

Let $\mathcal{C}$ be an $(\mathcal{S}, \mathcal{O})$-category, that is, a small simplicial category with object set $\mathcal{O}$. We can apply any monoidal functor $F: \mathcal{S} \to \mathcal{V}$ to get a $(\mathcal{V}, \mathcal{O})$-category. For example, let $P^n$ be the $n$th Postnikov section $P^n: S \to P^n S$. Then $P^n \mathcal{C}$ is a $(P^n S, \mathcal{O})$-category.

- $P^0 \mathcal{C}$ is equivalent to $\pi_0 \mathcal{C}$, an $\mathcal{O}$-category, but it is cofibrant. (In simplicial categories, it looks like $F_*(\pi_0 \mathcal{C})$.)
- For $n = 1$, note that we have a pair of semi-adjoint functors

\[
\hat{\pi}_1: \mathcal{S}Sets \rightleftarrows \mathcal{Gpd}: \text{nerve}
\]

which commute with products and thus extend to simplicial categories. Then $P^1 \mathcal{C}$ is equivalent to $\hat{\pi}_1 \mathcal{C}$ via the nerve in $(\mathcal{Gpd}, \mathcal{O}) - \text{Cat}$, or track categories [9].
- $P^2 \mathcal{C}$ is equivalent to a double track category (enriched in a certain type of double groupoid [25]).
- Higher-order models are only conjectural.

Note that $(\mathcal{S}, \mathcal{O})$-categories have $k$-invariants, taking values in the $(\mathcal{S}, \mathcal{O})$-cohomology of their Postnikov sections $P^n X$ with coefficients in the natural system (which is a $\hat{\pi}_1 X$-module) $\pi_{n+1} X$ [90]. Since all functors involved are monoidal (except cohomology), they pass from $\mathcal{S}Sets$ to $(\mathcal{S}, \mathcal{O})$.

These show the importance of $(P^n \mathcal{S}, \mathcal{O})$-categories, since:

1. they allow us to replace one model by a (hopefully simpler) one with the same weak homotopy type, since it is constructed inductively using “the same” $k$-invariants; and
2. they themselves carry homotopy-invariant information, as we will see later.
Even \((P^nS, O)\)-categories are too unwieldy to be useful, so we need to restrict the object sets, too. This leads to the notion of a “mapping algebra” \([6, §9]\): let \(C\) be a simplicial model category and \(A\) an object of \(C\). Define \(C_A\) to be the full sub-simplicial category of \(C\) generated by \(A\) under suspensions and coproducts of cardinality less than some \(\lambda\). Alternatively, we may take all (homotopy) colimits of bounded cardinality.

**Definition 13.1.** An \(A\)-mapping algebra is a simplicial functor \(X : C_A \to \mathcal{S}\).

**Example 13.2.** Choose an object \(Y\) of \(C\) and define \((MAY)(A') = \text{Map}_C(A', Y)\) for any object \(A'\) of \(C_A\). This is a realizable mapping algebra.

Note that if \(O = \text{ob}(C_A)\) and \(O^+ = O \cup \{*\}\), then \(X\) is just an \((\mathcal{S}, O^+)\)-category such that \(X|_O = C_A\) and \(\text{Map}_X(*, -) = \ast\).

**Definition 13.3.** An \(A\)-mapping algebra \(X\) is realizable if \(X\) preserves the limits in \(C_A^{\text{op}}\). In other words, \(X(\Sigma A') = \Omega X(A')\) and \(X(\vee A_i) = \prod_i X(A_i)\).

So, a realizable \(X\) is determined by \(X(A)\).

As a motivating example, let \(C = \text{Top}\) and \(A = S^1\). Then \(MA_{S^1} = \Omega Y\) with additional structure. In particular, it has an \(A_{\infty}\)-structure. The conclusion is that any realistic \(S^1\)-mapping algebra is realizable, i.e., \(X(A) = \Omega Y\) for some \(Y\). When \(A = S^k\), \(MA_{S^k}\) is a \(k\)-fold loop space, equipped with an action of all mapping spaces between (wedges of) spheres on it and its iterated loops. A realistic \(A\)-mapping algebra is any space \(X\) equipped with such an action. Since this includes in particular the \(A_{\infty}\) (or \(E(k)\)) structure, we see that any realistic \(A\)-mapping algebra is realizable.

For more general \(A\), even \(A = S^1 \vee S^2\), the situation is more complicated; the purely “algebraic” approach of analyzing the group structure does not work. However, by enhancing the structure of of an \(A\)-mapping algebra suitably one can still recover \(Y\) from \(X\), up to \(A\)-equivalence \([6, §10]\).

There is a dual version in which we map into \(A\) and its products and loop spaces. The realizable version is denoted by \(MA^A Y\).

**Example 13.4.** The space \(C^A\) may consist of all \(K(V, n)\) with \(V\) an \(\mathbb{F}_p\)-vector space. Note that all mapping spaces here are generalized Eilenberg-Mac Lane spaces.

If we apply the \(n\)th Postnikov section functor to an \(A\)-mapping algebra, we obtain an \(n - A\)-mapping algebra, which is defined to be a \((P^nS, O^+)\)-category extending \(P^nC_A\) as above. Again, it may or may not be \(n\)-realistic.

**Example 13.5.** When \(n = 0\), this is essentially a \(\pi_0C_A\)-algebra; if \(A\) is a homotopy cogroup object, this algebra is an algebraic theory in the sense of Lawvere \([49]\).

**Example 13.6.** Note that if \(Y\) is a connected space, then \(\pi_0\Omega^k Y = \pi_k Y\), so for \(A = S^1\), \(P^0MA_{S^1}Y\) encodes all homotopy groups of \(Y\), as well as the action of all primary homotopy groups.

What can we say about an \(n\)-realistic \(A\)-mapping algebra? (In other words, what is \(P^nX\) for \(X\) realistic, or something that behaves like it, as \(X\) may not exist? It should be like truncating an operad at level \(n\).) The answer is that we recover an \(n\)-stem for \(Y\) \([5, §1]\). For example, \(P^{n+k}X(k-1)\) is the \((k-1)\)-connective cover of \(P^{n+k}X\) with only homotopy groups from \(k\) to \(n + k\). We can’t recover all of \(Y\), since we can’t deloop.
We know that the $E_2$-term of the Adams spectral sequence for a space $Y$ is $\operatorname{Ext}^*_{A}(H^*(Y;\mathbb{F}_2), \mathbb{F}_2)$, which depends only on $H^*(Y)$ as a module or algebra over the Steenrod algebra. What about the higher terms?

**Theorem 13.7.** [8, 5, 7] The $E_r$-term of the (stable or unstable) Adams spectral sequence for $Y$ is determined by the $(r-2)$nd order derived functors of $M^AY$, where $A$ here is $\{ K(\mathbb{F}_p, n) \}_{n=1}^{\infty}$, and these may depend in turn on $P^{n-2}M^AY$, the $(r-2)$-dual stem.

**Remark 13.8.** At first glance it appears that $M^AY$ is uninteresting in this case, since all the spaces in question are products of $\mathbb{F}_p$-Eilenberg-Mac Lane spaces, so their $k$-invariants are trivial. But, this is not true of $C^A$ as an $(\mathcal{S}, \mathcal{O})$-category!

### 14. Application: The Cobordism Hypothesis

The main application of $(\infty, n)$-categories at this time is Lurie’s use of them in his proof of the cobordism hypothesis. We begin with Baez-Dolan’s original formulation of this conjecture.

Define a category $\text{Cob}(n)$ as follows.

- The objects are closed oriented $(n-1)$-dimensional manifolds $M$.
- $\text{Hom}(M, N)$ consists of diffeomorphism classes of cobordisms from $M$ to $N$, i.e., $n$-dimensional manifolds $B$ with $\partial B = \overline{M} \sqcup N$, where $\overline{M}$ is the manifold $M$ with the opposite orientation.

Notice that $\text{Cob}(n)$ is symmetric monoidal under the disjoint union. Let $\text{Vect}(k)$ be the category of vector spaces over a field $k$, and notice that this category is monoidal under the tensor product over $k$. The following definition is due to Atiyah [1].

**Definition 14.1.** A topological field theory of dimension $n$ is a symmetric monoidal functor $Z: \text{Cob}(n) \to \text{Vect}(k)$.

Notice that if $Z(M) = V$, then we must have $Z(\overline{M}) = V^\vee$, the dual vector space. In particular, vector spaces in the image of $Z$ should be finite-dimensional.

In dimension 1, a topological field theory is completely determined by its value on a point, since all 0-dimensional manifolds are just collections of points.

In dimension 2, a topological field theory is a commutative Frobenius algebra. The idea here is to break a cobordism up into manageable pieces along closed 1-dimensional manifolds.

We would like to do this kind of procedure in higher dimensions, but it doesn’t work as well, since we may need to cut along manifolds with boundary or manifolds with corners. This situation leads us to make a higher categorical version of $\text{Cob}(n)$.

**Definition 14.2.** The (weak) $n$-category $\text{Cob}(n)$ has:

- objects 0-dimensional manifolds,
- 1-morphisms cobordisms between them,
- 2-morphisms cobordisms between cobordisms,
- $n$-morphisms diffeomorphism classes of cobordisms between $\cdots$ cobordisms between cobordisms.

Then we define an $n$-extended topological field theory of dimension $n$ to be a symmetric monoidal functor $\text{Cob}_n(n) \to \mathcal{C}$, where $\mathcal{C}$ is some symmetric monoidal (weak) $n$-category, which is some generalization of $\text{Vect}(k)$. The images in $\mathcal{C}$ must
be “fully dualizable” in that they must have duals but also must have a notion of duals for morphisms up to level $n - 1$.

**Theorem 14.3. (Baez-Dolan Cobordism Hypothesis)** Let $\mathcal{C}$ be a symmetric monoidal weak $n$-category. Then the evaluation functor $Z \mapsto Z(\ast)$ defines a bijection between isomorphism classes of framed extended topological field theories and isomorphism classes of fully dualizable objects of $\mathcal{C}$.

This conjecture was proved as stated in dimension 1 by Baez and Dolan [2], and in dimension 2 by Schommer-Pries [66]. However, it gets difficult because weak $n$-categories get difficult to manage.

However, we still have lost information about our cobordisms by taking diffeomorphism classes at level $n$. Heuristically, we can define instead an $(\infty, n)$-category $\text{Bord}_n$ with:

- objects 0-dimensional manifolds,
- 1-morphisms cobordisms between them,
- 2-morphisms cobordisms between cobordisms,
- $n$-morphisms cobordisms between $\cdots$ cobordisms between cobordisms,
- $n + 1$-morphisms diffeomorphisms of the cobordisms of dimension $n$,
- $(n+2)$-morphisms isotopies of diffeomorphisms, and so forth.

In fact, $\text{Bord}_n$ can be realized as an $n$-fold complete Segal space. We actually want a more structured version, $\text{Bord}_n^{fr}$ where all manifolds are equipped with a framing. The symmetric monoidal structure can be described roughly as described in Hinich’s talk. The $(\infty, n)$-categorical version of the cobordism hypothesis was proved by Lurie, and can be “truncated” to prove the original version.

**Theorem 14.4.** Let $\mathcal{C}$ be a symmetric monoidal $(\infty, n)$-category. Then $Z \mapsto Z(\ast)$ determines a bijection between isomorphism classes of symmetric monoidal functors $\text{Bord}_n^{fr} \to \mathcal{C}$ and isomorphism classes of fully dualizable objects of $\mathcal{C}$.

The main steps of the proof are as follows:

1. Give an inductive formulation: assume true for $(\infty, n - 1)$-categories and describe the data needed to move up to $(\infty, n)$-categories and reduce the whole proof to this inductive step.
2. Reduce to the case where we have no additional structure on the manifolds (i.e., no framings).
3. Reformulate so that we can consider $(\infty, 1)$-categories rather than $(\infty, n)$-categories.
4. Use Morse theory to understand handle decompositions using a variation on $\text{Bord}_n$.
5. Show that the variation of $\text{Bord}_n$ is equivalent to $\text{Bord}_n$.

15. **The cobordism $(\infty, n)$-category as an $n$-fold complete Segal space**

(Additional talk given the following week at Hebrew University)

We want to know how cobordisms form an $(\infty, n)$-category, specifically in one of the precise models. Here, we will look at a simpler case of an $(\infty, 1)$-category informally described as having:

- objects closed $(n - 1)$-dimensional manifolds,
- 1-morphisms cobordisms between them,
• 2-morphisms diffeomorphisms,
• 3-morphisms isotopies, etc.

How can this information be encoded in a complete Segal space? Our treatment here is taken from [53].

We begin with some notation. Let $V$ be a $d$-dimensional vector space. Let $Sub_0(V)$ be the space of closed submanifolds $M \subseteq V$ of dimension $(n - 1)$, and let $Sub(V)$ be the space of compact $n$-dimensional manifolds $M \subseteq V \times [0, 1]$ such that $\partial M = M \cap (V \times \{0, 1\})$.

**Definition 15.1.** For $K \geq 0$, define the space

$$\text{SemiCob}(n)^V_k = \{(t_0 < t_1 < \cdots < t_k; M)\}$$

where each $t_i \in \mathbb{R}$ and $M \subseteq [t_0, t_k]$ is either

- a smooth submanifold of dimension $(n - 1)$, when $k = 0$, or
- a properly embedded submanifold of dimension $n$ which intersects each $V \times \{t_i\}$ transversally, for $k > 0$.

Notice that $\text{SemiCob}(n)_0^V$ is equivalent to $\mathbb{R} \times Sub_0(V)$, and that for $k > 0$, $\text{SemiCob}(n)^V_k$ is an open subspace of $Sub(V) \times \{t_0 < \cdots < t_k\}$.

A strictly increasing map $f: [k] \to [k']$ in $\Delta$ induces

$$f^*: \text{SemiCob}(n)^V_{k'} \to \text{SemiCob}(n)^V_k$$

given by

$$(t_0 < \cdots , t_k; M) \mapsto (t_{f(0)} < \cdots < t_{f(k)}; M \cap V \times [t_{f(0)}, t_{f(k)}]).$$

Hence, we get a semi-simplicial space (with face maps but no degeneracy maps) $\text{SemiCob}(n)^V$. Then define $\text{SemiCob}(n)$ as the colimit of $\text{SemiCob}(n)^V$, where $V$ ranges over all finite-dimensional subspaces of some model of $\mathbb{R}^\infty$.

If we actually want a simplicial space (with degeneracy maps), it gets more complicated.

**Definition 15.2.** Let $\text{PreCob}(n)^V_k$ be the space $\{(t_0 \leq \cdots \leq t_k; M)\}$ with $t_i \in \mathbb{R}$ and $M \subseteq V \times \mathbb{R}$ a possibly non-compact $n$-dimensional manifold such that the projection $M \to \mathbb{R}$ has critical values disjoint from $\{t_0, \ldots, t_k\}$. The subspace $\text{PreCob}_0(n)^V$ consists of the points actually satisfying $t_0 < \cdots < t_k$.

Since we allow equality between the points, we have degeneracy maps which repeat them, and hence a simplicial space $\text{PreCob}(n)^V$.

There is a levelwise weak equivalence

$$f: \text{PreCob}_0(n)^V \to \text{SemiCob}(n)^V$$

given by

$$(t_0 < \cdots < t_k; M) \mapsto (t_0 < \cdots < t_k; M \cap (V \times [t_0, t_k])).$$

Define $\text{PreCob}(n)$ to be the colimit of the $\text{PreCob}(n)^V$, as before. Then $\text{PreCob}(n)$ is a Segal space (possibly requiring Reedy fibrant replacement).

However, it is not necessarily complete: being so would violate the $s$-cobordism theorem. To make it complete, we could apply a localization functor in $CSS$. However, it is not usually a problem here; since we are mapping out of it, we really only need for it to be cofibrant.
