ABSTRACT
Miconazole nitrate is one of the antifungal agents applied to the skin. Miconazole nitrate has a low bioavailability if it implements for oral treatment due to poor solubility and has low absorption, therefore miconazole nitrate implemented as the antifungal agent for topically. In addition, the main problem of a drug is the treatment of topical for poor skin penetration ability. The aim of the current study was the comparison of the penetration and the antifungal activity of both dosages. Nanoemulsion and cream containing miconazole nitrate were made in three formulas namely 1%, 1.5%, 2% and one formula as a blank (without miconazole nitrate). The nanoemulsion is formulated with a low energy emulsification method. The formula was then evaluated for its particle size, drug release profile and antifungal activity test against *Tricophyton mentagrophytes*, *Microsporum canis* and *Candida albicans*. The particle size of nanoemulsion is 102.36 nm, 112.23 nm and 117.52 nm sequentially. The in-vitro release profile of nanoemulsion is between 65.81% to 71.09% while the cream is between 35.94% to 41.84% for 12 hours. Nanoemulsion contains miconazole nitrate 2% has an effective effect for the Cream 2% that number includes inhibit zone 28.2±1.15 mm for *Tricophyton mentagrophytes*, 21.0±0.77 mm for *Microsporum canis* and 23.7±0.90 mm for *Candida albicans*. From the current study, it can be concluded that nanoemulsion dosage forms result in improving the most penetration and antifungal activity.

Keywords: Nanoemulsion, Cream, Miconazole Nitrate, Franz Diffusion Cell, Antifungal.

INTRODUCTION
Topical treatment of fungal infections has various advantages, namely target to the infection area, reduce the risk for systemic side-effects, increase drug effectiveness and patient compliance.1 The efficiency of topical antifungal treatment is depending on the penetration of the drug by the target tissue. Therefore, the effective concentration of the drug must be delivered to the site of infection.2 Miconazole nitrate (Fig.-1) is a broad-spectrum antifungal agent of the imidazole group.3 These antifungals are fungicides that implemented for a treatment of topical and transdermal fungal infections.4 The drug is primarily implemented as a topical treatment for cutaneous mycoses. The bioavailability of miconazole nitrate is very low when implemented orally. But a presents problem for the treatment of cutaneous diseases due to the topical application is poor skin penetration capability.3 Various new methods like complexation method with cycloexetrin, submicron emulsion, and chewing gum for buccal administration has also been implemented in the development of the miconazole nitrate formulation but the drug content in the blood remains low.5

Rasayan J. Chem., 13(1), 529-534(2020)

To design effective miconazole nitrate formulations have known to become the main challenge due to efficacy able to severely limit by instability or poor solubility of a vehicle. A specific pharmaceutical preparation that can be implemented in drug delivery systems to resolve the problems is the nanoemulsion drug delivery system, which is applied to increase the solubility and bioavailability for lipophilic drugs. Nanoemulsions are colloidal dispersion systems that arise to the stability of thermodynamical conditions, collected from two immiscible liquids mix together by emulsifying agents (surfactants and co-surfactants) to form the single phase. Their long-term stability, easy preparation, and higher solubilization of drug molecules made it promising to become the drug delivery system. Nanoemulsion also has the potential as a carrier in topical treatment because it is able to optimize the dispersion of active substances in the skin layer. Nanoemulsion does not have creaming, sedimentation, and flocculation or coalescence compare to the macroemulsion.

**EXPERIMENTAL**

**Materials**
The materials in the current study are miconazole nitrate (from Kimia Farma Watudakon Jombang East Java Indonesia), oleic acid, tween 80, PEG 400, cetyl alcohol, propylene glycol, vaspeline, glyceryl monostearate, TEA, sodium metabisulfite, aqua dest, potato dextrose agar (PDA), Mc. Farland Solution, Physiological NaCl 0.9%. All the ingredients were of analytical grade.

**Formulation of Miconazole Nitrate Nanoemulsion**
Miconazole nitrate nanoemulsion was prepared by low energy emulsification method. Oil-in-water nanoemulsions were formulated at varied concentrations of miconazole nitrate. Nanoemulsion formulation in the absence of a miconazole nitrate was also prepared. The emulgators implemented were Tween 80 and PEG 400. The water phase which includes sodium metabisulfite and aquabidestilata was mixed and stirred with the help of magnetic stirrer until homogeneous. The oil phase was added to the water phase while adding the emlugator mixture and stirring using a magnetic stirrer, then the mixture was homogenized by a homogenizer that the speed was set at 1000 rpm for 60 minutes after that sonicated for 30 minutes until clear nanoemulsions were formed. The formula design of miconazole nitrate nanoemulsion is shown in Table-1.

**Table-1: Compositions of Miconazole Nitrate Nanoemulsion**

| Composition               | Formula  |
|---------------------------|----------|
|                          | F1A      | F2A     | F3A     | F4A     |
| Miconazole nitrate (% v/v)| -        | 1       | 1.5     | 2       |
| Oleic acid (% v/v)        | 8        | 8       | 8       | 8       |
| Tween 80 (% v/v)          | 25       | 25      | 25      | 25      |
| PEG 400 (% v/v)           | 5        | 5       | 5       | 5       |
| Sodium metabisulfite (% v/v) | 0.1     | 0.1     | 0.1     | 0.1     |
| Aquabidest ad (ml)        | 100      | 100     | 100     | 100     |

Note:
F1A: Nanoemulsion without containing Miconazole Nitrate (Blank)
F2A: Nanoemulsion containing 1% of Miconazole Nitrate
F3A: Nanoemulsion containing 1.5% of Miconazole Nitrate
F4A: Nanoemulsion containing 2% of Miconazole Nitrate
Particle Size Measurement of Nanoemulsion
Droplet sizes of nanoemulsion were measured by dynamic light scattering (DLS) by non-invasive back scatter technology. An experiment was conducted at 25°C on Zetasizer Nano ZS (Malvern Instruments, UK) provided by the helium-neon laser operating at 633 nm. The DLS result was analyzed by a method of Cumulants in which the intensity correlation function was related to a diffusion coefficient and eventually converted to a hydrodynamic size. The width of size distribution was referred to as a polydispersity index (PDI). The data obtained was represented as an average of three determinations.\(^1\)

Cycling Test
The nanoemulsion preparation was stored at 4°C±2°C for 24 h, then into the oven at 40°C±2°C for the next 24 h. This treatment is one cycle. The experiment was repeated for 6 cycles. After a cycling test, see the physical condition for nanoemulsion before then after the test.\(^1\)

Centrifugation Test
The sample was inserted into a centrifugation tube then inserted into a centrifugator with a spin speed 3800 rpm for 5 h. Treatment results are equivalent to a gravity effect for 1 year. After centrifugation was observed, the physical condition of the preparation compared before and after the test.\(^1\)

Preparation of Miconazole Nitrate Cream
All necessary materials were weighed. The materials were separated into two groups: The oil and water phases. The oil phase consists of vaseline, stearic acid, and cetyl alcohol melted over a water bath with a temperature of 70°C–75°C. After a perfect melt was implemented, miconazole nitrate into it. In a separate container, aqueous phases comprising aqua dest, propylene glycol, and TEA are dissolved in hot water. On a continuous phase, the water in a hot melt then slowly added to the oil phase with constant stirring at the temperature more or less 70°C, until a cream mass was obtained.\(^1\) The formula design of miconazole nitrate cream is shown in Table-2.

\[\text{Table-2: Compositions of Miconazole Nitrate Cream}\]

| Composition                  | Formula |
|------------------------------|---------|
|                              | F1B    | F2B    | F3B | F4B |
| Miconazole nitrate (% w/w)   | -      | 1      | 1.5 | 2   |
| Vaseline (% w/w)             | 5      | 5      | 5   | 5   |
| Cetyl alcohol (% w/w)        | 3      | 3      | 3   | 3   |
| Stearic acid (% w/w)         | 3      | 3      | 3   | 3   |
| Glyceryl monostearate (% w/w)| 3      | 3      | 3   | 3   |
| Propylene glycol (% w/w)     | 5      | 5      | 5   | 5   |
| TEA (% w/w)                  | 1      | 1      | 1   | 1   |
| Sodium metabisulfite (% w/w) | 0.1    | 0.1    | 0.1 | 0.1 |
| Aquabidest ad (g)            | 100    | 100    | 100 | 100 |

In Vitro Skin Permeation Studies of Miconazole Nitrate Nanoemulsion and Cream
The drug release kinetics studied implementing a modified Franz diffusion cell. Male rabbits weighing 1.8 kg were chosen for the in vitro studies.\(^1\) Hairs on the abdominal region were removed by the razor knife (Gillette Brand) with no break of the stratum corneum.\(^2\) During the experiment period, animals that anesthetized with chloroform and abdominal skin was established. The fatty material adhered to the dermis was carefully peeled off. Miconazole nitrate nanoemulsion was applied to the surface of the skin in the donor compartment, The samples were withdrawn at different time intervals as much as 0.5 mL from the receptor compartment and analyzing of drug content using a UV-Visible spectrophotometer.\(^1\)
In Vitro Antifungal Activity Test of Miconazole Nitrate Nanoemulsion and Cream

Ditch plate technique implemented for the study. It is a technique applied for the evaluation of bacteriostatic or fungistatic activities of the compound. The nanoemulsion preparation as much as 0.05 gram were located on the ditch cut of a plate. Freshly prepared culture loops of *Trichophyton mentagrophytes*, *Microsporum canis* and *Candida albicans* were streaked across the agar at a right angle from the ditch to the edge of the plate. Triplo was repeated in the same way. When the incubation established for 5 to 7 days at 25°C, the fungal growth was analyzed and then the diameter of the inhibit zone was measure horizontally and vertically.

RESULTS AND DISCUSSION

Particle Size Measurement of Nanoemulsion

Droplet sizes of nanoemulsion were measured by dynamic light scattering (DLS) by non-invasive backscatter technology. Measurement results show on Table-3.

| Formula | Particle size | Intensity |
|---------|--------------|-----------|
| F2A     | 102.36 nm    | 0.51      |
| F3A     | 112.23 nm    | 0.47      |
| F4A     | 117.52 nm    | 0.71      |

Cycling Test

All the formulas on the cycling test after 6 cycles, the nanoemulsion preparation remained weak yellow and odorless, and the cream preparations remained white and did not show phase separation.

Centrifugation Test

After all the formula was centrifuged at 3800 rpm for 5 hours, both nanoemulsion and cream preparations did not show phase separation.

In Vitro Skin Permeation Studies of Miconazole Nitrate Nanoemulsion and Cream

The drug release kinetics studied using a modified Franz diffusion cell. This test is carried out to find out how much miconazole nitrate is able to penetrate by the skin barrier. The cumulative amount of penetrated miconazole nitrate shows in Fig.-2.

![Fig.-2: The Cumulative Amount of Miconazole Nitrate Penetrated from the Nanoemulsion and Cream Preparations](image)

Based on the Fig.-2 shows that the cumulative amount of miconazole nitrate penetrated by rabbit skin during the 720-minute penetration test of each nanoemulsion preparations in sequence are 2165.20 µg/cm², 3387.81 µg/cm² and 4677.38 µg/cm² and from cream preparations are 1183.36 µg/cm², 1995.80 µg/cm² dan 2805.24 µg/cm². From these results, miconazole nitrate in nanoemulsion dosage form has a cumulative amount of penetration greater than the cream dosage form. This is because the nanoemulsion particle size is smaller than the cream which makes it easier for miconazole nitrate to penetrate. The small
particle size of nanoemulsion increases the surface area of the emulsion system so that penetration is better.  

**Comparison of Cumulative Percentage of Miconazole Nitrate Nanoemulsion and Cream Preparations**

The results obtained from the penetration of miconazole nitrate nanoemulsion preparations compared with cream preparations, as shown in Fig.-3.

![Graph showing cumulative percentage of miconazole nitrate penetrated in 720 minutes of nanoemulsion and cream preparations.]

Percentage of the cumulative amount of miconazole nitrate penetrated from each nanoemulsion preparation is 65.81%, 68.64% and 71.09% and from each cream formula are 35.94%, 40.44% and 41.84%. Overall, it can be seen that the nanoemulsion formula produces a greater percentage of cumulative amounts compared to the cream formula, this is probably due to the nanoemulsion formula has a smaller particle size than the cream so that it can cross the rough skin surface and can increase drug penetration. Nanoemulsion preparations can help dissolve lipophilic drugs, thereby increasing drug penetration by the skin membrane. Nanoemulsion has also been reported to have higher skin permeation compared to other drug delivery systems such as microemulsions and liposomes. Besides that, it is also due to the use of tween 80 as a surfactant which is also a penetration increasing. The theory is proven by previous studies, comparing nanoemulsion spray with cream, in which the nanoemulsion penetration ability was greater because the smaller particle size obtained.

**In vitro Antifungal Activity Test of Miconazole Nitrate Nanoemulsion and Cream**

The antifungal activity test of the formula observed by seeing the minimum inhibition using the punch hole method with a hole diameter of 6 mm on the agar media against *Trycophyton mentagrophytes*, *Microsporum canis* and *Candida albicans*. Table-4 showed the result of the antifungal activity test for nanoemulsion and cream miconazole nitrate. These results show that the antifungal activity of nanoemulsion is better than the cream dosage form because all concentrations are above the antimicrobial activity requirements with a range of 14-16 mm.
CONCLUSION

According to the observation, this study resulted in the formula of miconazole nitrate nanoemulsion had a higher cumulative percent penetration and antifungal activity compared to the formula of miconazole nitrate cream. Meanwhile, the pharmacodynamic and pharmacokinetic evaluation of the system in human volunteers is still needed for confirmation.

ACKNOWLEDGMENT

Authors of this study thanks to Kimia Farma Watudakon Jombang, East Java Indonesia for the miconazole nitrate samples. In addition, we are thankful for the supports from the Faculty of Pharmacy, Universitas Sumatera Utara, Indonesia.
