GENERALIZED DIFFERENTIATION WITH POSITIVELY HOMOGENEOUS MAPS: APPLICATIONS IN SET-VALUED ANALYSIS AND METRIC REGULARITY

C.H. JEFFREY PANG

Abstract. We propose a new concept of generalized differentiation of set-valued maps that captures first order information. This concept encompasses the standard notions of Fréchet differentiability, strict differentiability, calmness and Lipschitz continuity in single-valued maps, and the Aubin property and Lipschitz continuity in set-valued maps. We present calculus rules, sharpen the relationship between the Aubin property and coderivatives, and study how metric regularity and open covering can be refined to have a directional property similar to our concept of generalized differentiation. Finally, we discuss the relationship between the robust form of generalized differentiation and its one sided counterpart.

1. Introduction

We say that $S$ is a set-valued map (or a multi-valued function, or multifunction) if for all $x \in X$, $S(x)$ is a subset of $Y$, and we denote set-valued maps by $S : X \mapsto Y$. Many problems of feasibility, control, optimality and equilibrium are set-valued in nature, and are best treated with methods in set-valued analysis. The texts \cite{4,5,23} contain much of the theory of set-valued analysis. Set-valued analysis serves as a foundation for the theory of differential inclusions \cite{3,24}, control theory \cite{15} and variational analysis \cite{40,32,14}, which in turn have many applications in applied...
mathematics. We refer to these texts for the abundant bibliography on the history of set-valued analysis.

The main contribution of this paper is to introduce a new concept of generalized differentiation (Definitions 4.1 and 4.6) using positively homogeneous maps. Any reasonable definition of a derivative for set-valued maps has to describe changes in the set in terms of the input variables. Using the Pompieu-Hausdorff distance (a metric on the space of nonempty compact sets), one obtains the classical definition of Lipschitz continuity of set-valued maps. The concept introduced in this paper provides a more precise tool that incorporates first order information in a set-valued map, encompassing the standard notions of Fréchet differentiability, strict differentiability, calmness and Lipschitz continuity in single-valued maps, and the Aubin property and Lipschitz continuity in set-valued maps. We illustrate how this new concept relates to, and extends, existing methods in variational and set-valued analysis. To motivate our discussion, we revisit the relation between the Clarke subdifferential and Clarke Jacobian and the nonsmooth behavior of functions that can be traced back to [19].

Other than the first four sections which provide the necessary background for the rest of the paper, the last four sections can be read in any order. In Section 3, we recall generalized differentiation for single-valued functions, which was first proposed by Ioffe [18, 19]. We relate the generalized derivative to common notions in classical and variational analysis, paying particular attention to the Clarke subdifferential and the Clarke Jacobian. In Section 4, we define generalized differentiation for set-valued maps, and illustrate the lack of relation between our generalized derivatives and the notions of set-valued derivatives based on the tangent cones, namely semidifferentiability [34] and proto-differentiability [39]. We present calculus rules in Section 5.

The Aubin property (see Definition 4.7), which is commonly attributed to [1], is a method of analyzing local Lipschitz continuity of set-valued maps. In Section 6, we revisit the classical relationship between the Aubin property and the coderivatives of a set-valued map. This relationship is referred to as the Mordukhovich criterion in [40]. Since the coderivatives of a set-valued map can be calculated in many applications and enjoy an effective calculus, this relationship is an important tool in the study of the Lipschitz properties of set-valued maps. We will show that the coderivatives actually give more information on the local Lipschitz continuity property in our language of generalized derivatives.

It is well known that the Aubin property is related to metric regularity and open covering [6, 30, 35]. Open covering is sometimes known as linear openness. Metric regularity is important in the analysis of solutions to \( \bar{y} \in S(\bar{x}) \), while open covering studies local covering properties of a set-valued map. Both metric regularity and open covering can be viewed as a study of set-valued maps whose inverse has the Aubin property. For more on metric regularity, we refer the reader to [40, 32, 13, 21, 22]. In Section 7, we take a new look at metric regularity and open covering in view of our definitions of the generalized derivatives. We study metric regularity and open covering in a much broader framework, illustrating that a directional behavior similar to that in our definition of generalized derivatives is present in metric regularity and open covering.

In Section 8, we discuss how the (basic and strict) generalized derivatives defined in Sections 3 and 4 relate to each other. As particular cases, we obtain an equivalent
2. Preliminaries and notation

Throughout this paper, we shall assume that $X$ and $Y$ are Banach spaces. In most cases, we follow the notation of [10]. Given two sets $A, B \subset X$, the notation $A + B$ stands for the Minkowski sum of two sets, defined by

$$A + B := \{a + b \mid a \in A, b \in B\}.$$ 

The notation $A - B$ is interpreted as $A + (-B)$. We use $\langle \cdot, \cdot \rangle : X^* \times X \to \mathbb{R}$, where $\langle \zeta, x \rangle := \zeta(x)$, to denote the usual dual relation. In Hilbert spaces (and hence in $\mathbb{R}^n$), $\langle \cdot, \cdot \rangle$ reduces to the usual inner product. The notation $x \to \bar{x}$ means that we take sequences $\{x_i\}_{i=1}^{\infty} \subset D$ such that $\lim_{i \to \infty} x_i = \bar{x}$. The closed ball with center $x$ and radius $r$ is denoted by $B(x, r)$, while $B$ denotes the closed unit ball.

We say that the set-valued map $S : X \rightrightarrows Y$ is closed-valued if $S(x)$ is closed for all $x \in X$, and it is convex-valued if $S(x)$ is convex for all $x \in X$. A closed set-valued map is a map whose graph is closed. We say that $C \subset X$ is a cone if $0 \in C$ and $\lambda x \in C$ for all $\lambda > 0$ and $x \in C$.

The graph of a set-valued map $\text{gph}(S) \subset X \times Y$ is the set $\{(x, y) \mid y \in S(x)\}$. The set-valued map $S^{-1} : Y \rightrightarrows X$ is defined by $S^{-1}(y) := \{x \mid y \in S(x)\}$, and $\text{gph}(S^{-1}) = \{(y, x) \mid (x, y) \in \text{gph}(S)\}$.

**Definition 2.1.** A set-valued map $T : X \rightrightarrows Y$ is positively homogeneous if

$$T(0)$$ is a cone, and $T(kw) = kT(w)$ for all $k > 0$ and $w \in X$.

It is clear that $T$ is positively homogeneous if and only if $\text{gph}(T)$ is a cone. If $T_1, T_2 : X \rightrightarrows Y$ are two set-valued maps such that $T_1(w) \subset T_2(w)$ for all $w \in X$, then we write this property as $T_1 \subset T_2$. We denote the set-valued map $T(-\cdot) : X \rightrightarrows Y$ to be $T(-\cdot)(w) := T(-w)$.

We recall the definition of inner limits of a set valued map.

**Definition 2.2.** When $S : X \rightrightarrows Y$ is a set-valued map, we say that

$$\limsup_{x \to \bar{x}} S(x) := \{y \in Y \mid \liminf_{x \to \bar{x}} d(y, S(x)) = 0\}$$

is the outer limit of $S$ at $\bar{x}$ and

$$\liminf_{x \to \bar{x}} S(x) := \{y \in Y \mid \lim_{x \to \bar{x}} d(y, S(x)) = 0\}$$

is the inner limit of $S$ at $\bar{x}$. When the outer and inner limits coincide, it is called the limit.

The above definition of limits are equivalent to those in [10] by [10] Exercise 4.2]. We recall the definitions of outer and inner semicontinuity.

**Definition 2.3.** For a closed-valued mapping $S : X \rightrightarrows Y$ and a point $\bar{x} \in X$:

(1) $S$ is upper semicontinuous at $\bar{x}$ if for any open set $U$ such that $S(\bar{x}) \subset U$, there is a neighborhood $V$ of $\bar{x}$ such that $S(x) \subset U$ for all $x \in V$.

(2) $S$ is outer semicontinuous at $\bar{x}$ if for any open set $U$ such that $S(\bar{x}) \subset U$ and $\rho > 0$, there is a neighborhood $V$ of $\bar{x}$ such that $S(x) \cap \rho B \subset U$ for all $x \in V$.

Equivalently, $S$ is outer semicontinuous at $\bar{x}$ if $\limsup_{x \to \bar{x}} S(x) \subset S(\bar{x})$. 

A criterion for strict differentiability of set-valued maps, and a relationship between calmness and Lipschitz continuity in both single-valued and set-valued maps. As far as we are aware, the relation between calmness and Lipschitz continuity in set-valued maps was first discussed in [20] [37].
(3) $S$ is inner semicontinuous at $\bar{x}$ if $S(\bar{x}) \subset \liminf_{x \to \bar{x}} S(x)$.

(4) $S$ is continuous at $\bar{x}$ if it is both outer and inner semicontinuous there.

We caution that the terminology used to denote upper semicontinuity and outer semicontinuity is not consistent in the literature. In finite dimensions, outer semicontinuity is equivalent to the notation in [40] (see [40, Proposition 5.12]), where $U$ is created by $S(\bar{x}) + \epsilon \mathbb{B}$.

Outer semicontinuity is better suited to handle set-valued maps with unbounded value sets $S(x)$. For example, the set-valued map $S: \mathbb{R} \rightrightarrows \mathbb{R}^2$ defined by

$$S(\theta) := \{(t \cos \theta, t \sin \theta) \mid t \geq 0\}$$

(see [40] Figure 5-7 or [7] Page 27) is not upper semicontinuous anywhere but is outer semicontinuous, and in fact continuous, everywhere. When $S(\bar{x})$ is bounded, upper and outer semicontinuity are equivalent. We will not use upper semicontinuity in this paper.

To simplify the notation, given any map $T: X \rightrightarrows Y$ and constant $\delta > 0$, denote $(T + \delta): X \rightrightarrows Y$ to be the map

$$(T + \delta)(w) := T(w) + \delta|w|\mathbb{B}.$$ 

3. GENERALIZED DIFFERENTIABILITY OF SINGLE-VALUED MAPS

The emphasis of this section is the generalized differentiability of single-valued maps $f: X \to Y$. Much of the theory is already in [19], but we concentrate on the key results that we will extend for the set-valued case in later sections. We now begin with our first definition of generalized differentiability.

**Definition 3.1.** ($T$-differentiability) Let $T: X \rightrightarrows Y$ be a positively homogeneous set-valued map. We say that $f: X \to Y$ is $T$-differentiable at $\bar{x}$ if for any $\delta > 0$, there exists a neighborhood $V$ of $\bar{x}$ such that

$$f(x) \in f(\bar{x}) + T(x - \bar{x}) + \delta|x - \bar{x}|\mathbb{B} \text{ for all } x \in V.$$ 

We say that $f: X \to Y$ is strictly $T$-differentiable at $\bar{x}$ if for any $\delta > 0$, there exists a neighborhood $V$ of $\bar{x}$ such that

$$f(x) \in f(x') + T(x - x') + \delta|x - x'|\mathbb{B} \text{ for all } x, x' \in V.$$ 

The map $T: X \rightrightarrows Y$ is referred to as a prederivative when $f$ is $T$-differentiable, and as the strict prederivative when $f$ is strictly $T$-differentiable in [19] Definition 9.1]. The definition of $T$-differentiability includes the familiar concepts of differentiability and Lipschitz continuity as special cases.

**Example 3.2.** (Examples of $T$-differentiability) Let $f: X \to Y$ be a single-valued map.

1. When $T: X \to Y$ is a (single-valued) continuous linear map, $T$-differentiability is precisely Fréchet differentiability with derivative $T$, and strict $T$-differentiability is precisely strict differentiability with derivative $T$.

2. When $T: X \rightrightarrows Y$ is defined by $T(w) = \kappa|w|\mathbb{B}$, $T$-differentiability is precisely calmness with modulus $\kappa$ (i.e., $|f(x) - f(\bar{x})| \leq \kappa|x - \bar{x}| + o(|x - \bar{x}|)$), and strict $T$-differentiability is precisely local Lipschitz continuity with modulus $\kappa$. 
Strict $T$-differentiability is more robust than $T$-differentiability. The function $f : \mathbb{R} \to \mathbb{R}$ defined by
$$f(x) := \begin{cases} x^2 \sin(x^{-2}) & \text{if } x \neq 0 \\ 0 & \text{if } x = 0 \end{cases}$$
is Fréchet differentiable at 0 but not Lipschitz there.

With the right choice of $T$, $T$-differentiability can also handle inequalities.

**Example 3.3.** (Inequalities with $T$-differentiability) Let $f : X \to \mathbb{R}$ be a single-valued map.

1. $f : X \to \mathbb{R}$ is calm from below at $\bar{x}$ with modulus $\kappa$, i.e., $f(x) \geq f(\bar{x}) - \kappa |x - \bar{x}| + o(|x - \bar{x}|)$, if and only if $f$ is $T$-differentiable there, where $T : X \rightrightarrows \mathbb{R}$ is defined by $T(w) = [-\kappa|w|, \infty)$.

2. The vector $v \in X^*$ is a Fréchet subgradient of $f$ at $\bar{x}$ if and only if $f$ is $T$-differentiable there, where $T : X \rightrightarrows \mathbb{R}$ is defined by $T(w) = \{\langle v, w \rangle, \infty\}$.

3. The convex set $C \subset X^*$ is a subset of the Fréchet subdifferential of $f$ at $\bar{x}$ if and only if $f$ is $T$-differentiable there, where $T : X \rightrightarrows \mathbb{R}$ is defined by $T(w) = \sup_{v \in C} \{\langle v, w \rangle, \infty\}$.

It is clear from the definitions that if $f$ is $T_1$-differentiable at $\bar{x}$, and $T_2$ satisfies $T_2 \supset T_1$, then $f$ is $T_2$-differentiable at $\bar{x}$ as well.

At this point, we mention connections to other notions of generalized derivatives for single-valued functions close to the definition of (strict) $T$-differentiability. Semidifferentiability, as is recorded in [10, Definition 7.20], can be traced back to [33], and is equivalent to the case where $T : X \rightrightarrows Y$ is continuous and single-valued (see [10, Section 9D]). Semidifferentiability for single-valued maps is not to be confused with semidifferentiability for set-valued maps defined in Definition [4,10].

We now look at a slightly nontrivial example involving the Clarke subdifferential [8].

**Definition 3.4.** [10, Section 2.1] (Clarke subdifferential) Let $X$ be a Banach space. Suppose $f : X \to \mathbb{R}$ is locally Lipschitz around $\bar{x}$. The Clarke generalized directional derivative of $f$ at $\bar{x}$ in the direction $v \in X$ is defined by
$$f^\circ(\bar{x}; v) = \lim_{t \downarrow 0, t \to \bar{x}} \sup \frac{f(x + tv) - f(x)}{t},$$
where $x \in X$ and $t$ is a positive scalar. The Clarke subdifferential of $f$ at $\bar{x}$, denoted by $\partial_C f(\bar{x})$, is the convex subset of the dual space $X^*$ given by
$$\{\zeta \in X^* | f^\circ(\bar{x}; v) \geq \langle \zeta, v \rangle \text{ for all } v \in X\}.$$

The Clarke subdifferential enjoys a mean value theorem. For $C \subset X^*$, define the set $(C, w)$ by $\{(c, w) | c \in C\}$. The following result is due to Lebourg [25], which has since been generalized in other ways.

**Theorem 3.5.** [25] (Nonsmooth mean value theorem) Suppose $x_1, x_2 \in X$ and $f$ is Lipschitz on an open set containing the line segment $[x_1, x_2]$. Then there exists a point $u \in (x_1, x_2)$ such that
$$f(x_2) - f(x_1) \in \langle \partial_C f(u), x_2 - x_1 \rangle.$$

We show how the Clarke subdifferential relates to $T$-differentiability. For extensions and a more general treatment of the following result, we refer the reader to [19, Sections 9, 10].
Theorem 3.6. (Clarke subdifferential and T-differentiability) Let \( f : X \to \mathbb{R} \) be a Lipschitz function, and \( C \) be a nonempty weak*-compact convex subset of \( X^* \). If \( f \) is strictly T-differentiable at \( \bar{x} \), where \( T : X \to \mathbb{R} \) is defined by \( T(w) = \langle C, w \rangle \), then \( \partial C f(\bar{x}) \subset C \). The converse holds if the map \( x \mapsto \partial C f(x) \) is outer semicontinuous at \( \bar{x} \), which is the case when \( X = \mathbb{R}^n \).

Proof. If \( f \) is strictly T-differentiable at \( \bar{x} \), then for any direction \( h \in X \), the Clarke directional derivative is

\[
\max_{v \in \partial C f(\bar{x})} \langle v, h \rangle = f^\circ(\bar{x}; h) = \limsup_{x \to \bar{x}, t \to 0} \frac{f(x + th) - f(x)}{t} \leq \max_{v \in C} \langle v, h \rangle.
\]

Suppose on the contrary that \( v' \in \partial C f(\bar{x}) \setminus C \). Then there exists a direction \( h' \) and some \( \alpha \in \mathbb{R} \) such that \( \langle v', h' \rangle > \alpha \) but \( \max_{v \in C} \langle v, h' \rangle \leq \alpha \). This is a contradiction, which shows that \( \partial C f(\bar{x}) \subset C \).

We now prove the converse. It is well-known that when \( X = \mathbb{R}^n \), the Clarke subdifferential mapping of a Lipschitz function is outer semicontinuous. See \[40\] for example. Suppose that \( \partial C f(\bar{x}) \subset C \). By outer semicontinuity, given any \( \delta > 0 \), there is some \( \epsilon > 0 \) such that \( \partial C f(x) \subset C + \delta B \) for all \( x \in B(\bar{x}, \epsilon) \). Theorem 3.8 states that for any points \( x_1, x_2 \in B(\bar{x}, \epsilon) \), there is an \( x' \in (x_1, x_2) \) such that

\[
f(x_1) - f(x_2) < \langle \partial C f(x'), x_1 - x_2 \rangle.
\]

This immediately implies that \( f(x_1) \in f(x_2) + \langle C, x_1 - x_2 \rangle + \delta \|x_1 - x_2\| B \), and hence strict T-differentiability.

It is well known that in finite dimensions, the Clarke subdifferential is the convex hull of the limit of gradients taken over where the function is differentiable. We now recall Rademacher’s theorem.

Theorem 3.7. (Rademacher’s Theorem) Let \( O \subset \mathbb{R}^n \) be open, and let \( f : O \to \mathbb{R}^m \) be Lipschitz. Let \( D \) be the subset of \( O \) consisting of the points where \( F \) is differentiable. Then \( O \setminus D \) is a set of measure zero in \( \mathbb{R}^n \). In particular, \( D \) is dense in \( O \), i.e., \( \text{cl } D \supset O \).

Closely related to the Clarke subdifferential is the Clarke Jacobian that was first introduced in \[9\].

Definition 3.8. (Clarke Jacobian) Let \( f : O \to \mathbb{R}^m \) be Lipschitz, with \( O \subset \mathbb{R}^n \) open, and let \( D \subset O \) consist of the points where \( f \) is differentiable. The Clarke Jacobian at \( \bar{x} \) is defined by

\[
\nabla f(\bar{x}) := \text{conv}\{A \in \mathbb{R}^{m \times n} : \exists x_i \to \bar{x} \text{ with } x_i \in D, \nabla f(x_i) \to A\}.
\]

It is clear from Rademacher’s Theorem that the Clarke Jacobian is a nonempty, compact set of matrices. For \( m = 1 \), it is well-known that the Clarke Jacobian reduces to the Clarke subdifferential. The following result is equivalent to \[19\] Proposition 10.9, and is a generalization of a result that is well known for \( m = 1 \).

Theorem 3.9. (Clarke Jacobian and T-differentiability) Let \( f : O \to \mathbb{R}^m \) be Lipschitz on an open set \( O \subset \mathbb{R}^n \). At each \( \bar{x} \in O \), \( f \) is T-differentiable at \( \bar{x} \), where
\( T : \mathbb{R}^n \rightrightarrows \mathbb{R}^m \) is defined by

\[
T(w) := \{ Aw \mid A \in \nabla f(\bar{x}) \}.
\]

**Proof.** In the case \( O = \mathbb{R}^n \), a useful equivalent condition for a set \( C \subset \mathbb{R}^n \) to be of measure zero is this: with respect to any vector \( w \neq 0 \), \( C \) is of measure zero if and only if the set \( \{ \tau \mid x + \tau w \in C \} \subset \mathbb{R} \) is of measure zero (in the one-dimensional sense) for all \( x \) outside a set of measure zero. Let \( D \) be the subset of \( O \) on which \( f \) is differentiable.

Fix \( w \neq 0 \) and let \( x \in O \) and \( \tau > 0 \) be such that \( [x, x + \tau w] \cap (O \setminus D) \) has (one dimensional) measure zero. Then the function \( \varphi(t) = f(x + tw) \) is Lipschitz continuous for \( t \in [0, \tau] \). Lipschitz continuity guarantees that \( \varphi(\tau) = \varphi(0) + \int_0^\tau \varphi'(t)dt \), and in this integral a negligible set of \( t \) values can be disregarded. Thus, the integral is unaffected if we concentrate on \( t \) values such that \( x + tw \in D \), in which case \( \varphi'(t) = \nabla f(x + tw)(w) \).

For any \( \epsilon > 0 \), we can consider a neighborhood \( O' \) of \( \bar{x} \) so that whenever \( x \in O' \setminus D \), then \( \nabla f(x) \in \nabla f(\bar{x}) + \epsilon B \). We have

\[
\begin{align*}
\varphi(t) &= f(x + \tau w) \\
&= \varphi(0) + \int_0^\tau \varphi'(t)dt \\
&= f(x) + \int_0^\tau \nabla f(x + tw)(w)dt \\
&\subset f(x) + \int_0^\tau T(w) + \epsilon|w|Bdt \\
&\subset f(x) + T(\tau w) + \epsilon|\tau w|B.
\end{align*}
\]

The case where \( \nabla f(x + tw) \) does not exist for all \( t \) in a set of nonzero measure can be treated easily by perturbing \( x \). This establishes the \( T \)-differentiability of \( f \). \( \square \)

In Theorem 3.9 it is clear that there can be no closed convex valued positively homogeneous map \( T' \subseteq T \) such that \( f \) is \( T' \)-differentiable at \( \bar{x} \).

4. **Generalized differentiability of set-valued maps**

In this section, we move on to define the generalized differentiability of set-valued maps and state some basic properties. Here is the first definition of the differentiability of a set-valued map.

**Definition 4.1.** (\( T \)-differentiability) Let \( T : X \rightrightarrows Y \) be a positively homogeneous set-valued map.

(a) We say that \( S : X \rightrightarrows Y \) is outer \( T \)-differentiable at \( \bar{x} \) if for any \( \delta > 0 \), there exists a neighborhood \( V \) of \( \bar{x} \) such that

\[
S(x) \subset S(\bar{x}) + T(x - \bar{x}) + \delta|x - \bar{x}|B \quad \text{for all } x \in V.
\]

It is inner \( T \)-differentiable at \( \bar{x} \) if the formula above is replaced by

\[
S(\bar{x}) \subset S(x) - T(x - \bar{x}) + \delta|x - \bar{x}|B \quad \text{for all } x \in V.
\]

It is \( T \)-differentiable at \( \bar{x} \) if it is both outer \( T \)-differentiable and inner \( T \)-differentiable.

(b) We say that \( S : X \rightrightarrows Y \) is strictly \( T \)-differentiable at \( \bar{x} \) if for any \( \delta > 0 \), there exists a neighborhood \( V \) of \( \bar{x} \) such that

\[
S(x) \subset S(x') + T(x - x') + \delta|x - x'|B \quad \text{for all } x, x' \in V.
\]
It is elementary that if $S : X \rightrightarrows Y$ is a single-valued map $S : X \to Y$, then the definitions of outer $T$-differentiability, inner $T$-differentiability and $T$-differentiability in Definition 4.1(a) coincide.

The case $T(w) := \kappa |w| \mathcal{B}$, where $\kappa \geq 0$ is finite, is well studied in variational analysis. In the definitions of calmness and Lipschitz continuity below, we recall the notation for $\kappa$ commonly used in variational analysis. Calmness was first referred to as “upper Lipschitzian” by Robinson [36], who established this property for polyhedral mappings.

**Definition 4.2.** (Calmness and Lipschitzness) (a) We say that $S : X \rightrightarrows Y$ is *calm* at $\bar{x}$ if there exists a neighborhood $V$ of $\bar{x}$ and $\kappa \geq 0$ such that

$$S(x) \subset S(\bar{x}) + \kappa |x - \bar{x}| \mathcal{B} \text{ for all } x \in V.$$ 

The infimum of all constants $\kappa$ is the *calmness modulus*, denoted by $\text{clm} S(\bar{x})$. Calmness at $\bar{x}$ is equivalent to outer $T$-differentiability at $\bar{x}$, where $T : X \rightrightarrows Y$ is defined by $T(w) := [\text{clm} S(\bar{x})] |w| \mathcal{B}$.

(b) We say that $S : X \rightrightarrows Y$ is *Lipschitz* at $\bar{x}$ if there exists a neighborhood $V$ of $\bar{x}$ and $\kappa > 0$ such that

$$S(x) \subset S(x') + \kappa |x - x'| \mathcal{B} \text{ for all } x, x' \in V.$$ 

The infimum of all constants $\kappa$ is the *Lipschitz modulus*, denoted by $\text{lip} S(\bar{x})$. Lipschitz continuity at $\bar{x}$ is equivalent to strict $T$-differentiability at $\bar{x}$, where $T : X \rightrightarrows Y$ is defined by $T(w) := [\text{lip} S(\bar{x})] |w| \mathcal{B}$.

Consider the case where there is some $\kappa \geq 0$ such that $T : X \rightrightarrows Y$ satisfies $T(w) \subset \kappa |w| \mathcal{B}$ for all $w \in X$. It follows straight from the definitions that if $S : X \rightrightarrows Y$ is outer $T$-differentiable and maps to compact sets, then it is outer semicontinuous. The same relations hold for inner $T$-differentiability and inner semicontinuity, and for $T$-differentiability and continuity. We remark that strict $T$-differentiability implies strict continuity in the sense of [10] Definition 9.28], but not vice versa. Their difference is analogous to the difference between upper semicontinuity and outer semicontinuity.

We motivate this definition of set-valued differentiability with Proposition 4.4, whose proof is straightforward. We now recall the Pompieu-Hausdorff distance.

**Definition 4.3.** (Pompieu Hausdorff distance) For $C, D \subset X$ closed and nonempty, the *Pompieu-Hausdorff distance* between $C$ and $D$ is the quantity

$$d(C, D) := \inf \{ \eta \mid C \subset D + \eta \mathcal{B}, D \subset C + \eta \mathcal{B} \}.$$ 

The Pompieu-Hausdorff distance is a metric on compact subsets of $X$. In fact, the motivation of calmness and Lipschitz continuity in Definition 4.2 comes from the Pompieu-Hausdorff distance. To motivate the definition of $T$-differentiability, we note the following result.

**Proposition 4.4.** (Single-valued $T$-differentiability) Suppose $S : X \rightrightarrows Y$ is single-valued.

1. Let $T : X \to Y$ be a single-valued map. Then $S$ is $T$-differentiable at $\bar{x}$ if and only if for any $\delta > 0$, there is a neighborhood $V$ of $\bar{x}$ such that

$$d(S(\bar{x}) + T(x - \bar{x}), S(x)) \leq \delta |x - \bar{x}| \text{ for all } x \in V.$$
Remark 4.5. (More precise measurement of sets) We can rewrite the Pompieu-Hausdorff distance as

\[ d(C, D) = \inf \{ \eta \mid C \subset D + E_1, D \subset C + E_2, C \subset \eta \mathcal{B}, E_2 \subset \eta \mathcal{B} \}. \]

In certain situations, it might be useful to study sets \( E + D \) instead of just taking them to be \( \eta \mathcal{B} \).

As is well-known in set-valued analysis, setting restrictions on the range gives a sharper analysis at the points of interest. We make the following definitions with this in mind.

**Definition 4.6.** (Pseudo \( T \)-differentiability) Let \( S : X \rightrightarrows Y \) be a set-valued map such that \( \bar{y} \in S(\bar{x}) \).

1. Let \( T : X \rightrightarrows Y \) be a set-valued map. We say that \( S \) is pseudo outer \( T \)-differentiable at \( \bar{x} \) for \( \bar{y} \) if for any \( \delta > 0 \), there exist neighborhoods \( V \) of \( \bar{x} \) and \( W \) of \( \bar{y} \) such that

\[ S(x) \cap W \subset S(\bar{x}) + T(x - \bar{x}) + \delta \| x - \bar{x} \| \mathcal{B} \text{ for all } x \in V. \]

It is pseudo inner \( T \)-differentiable at \( \bar{x} \) for \( \bar{y} \) if

\[ S(\bar{x}) \cap W \subset S(x) - T(x - \bar{x}) + \delta \| x - \bar{x} \| \mathcal{B} \text{ for all } x \in V. \]

It is pseudo \( T \)-differentiable at \( \bar{x} \) for \( \bar{y} \) if it is both pseudo outer \( T \)-differentiable and pseudo inner \( T \)-differentiable there.

2. Let \( T : X \rightrightarrows Y \) be a positively homogeneous set-valued map. We say that \( S \) is pseudo strictly \( T \)-differentiable at \( \bar{x} \) for \( \bar{y} \) if for any \( \delta > 0 \), there exist neighborhoods \( V \) of \( \bar{x} \) and \( W \) of \( \bar{y} \) such that

\[ S(x) \cap W \subset S(x') + T(x - x') + \delta \| x - x' \| \mathcal{B} \text{ for all } x, x' \in V. \]

Again, the case \( T(w) := \kappa \| w \| \mathcal{B} \) is of particular interest. The Aubin property was first introduced as pseudo-Lipschitzness in \([1]\).

**Definition 4.7.** (Calmness and Aubin property) Let \( S : X \rightrightarrows Y \) be a set-valued map such that \( \bar{y} \in S(\bar{x}) \).

1. We say that \( S \) is calm at \( \bar{x} \) for \( \bar{y} \) if there exist neighborhoods \( V \) of \( \bar{x} \) and \( W \) of \( \bar{y} \), and \( \kappa \geq 0 \) such that

\[ S(x) \cap W \subset S(\bar{x}) + \kappa \| x - \bar{x} \| \mathcal{B} \text{ for all } x \in V. \]

The infimum of all such constants \( \kappa \) is the calmness modulus, denoted by \( \text{clm} S(\bar{x} \mid \bar{y}) \). Calmness is precisely pseudo outer \( T \)-differentiability, where \( T : X \rightrightarrows Y \) is defined by \( T(w) := \text{clm} S(\bar{x} \mid \bar{y}) \| w \| \mathcal{B} \).
(2) We say that $S : X \supseteq Y$ has the Aubin Property at $\bar{x}$ for $\bar{y}$ if there exist neighborhoods $V$ of $\bar{x}$ and $W$ of $\bar{y}$, and $\kappa \geq 0$ such that

$$S(x) \cap W \subset S(x') + \kappa|x - x'|B$$

for all $x, x' \in V$.

The infimum of all such constants $\kappa$ is the graphical modulus, denoted by $\text{lip} S(\bar{x} | \bar{y})$. The Aubin property is also known as the pseudo-Lipschitz property and as the Lipschitz-like property. The Aubin property is precisely pseudo strict $T$-differentiability, where $T : X \supseteq Y$ is defined by $T(w) := [\text{lip} S(\bar{x} | \bar{y})]|w|B$.

While the Clarke subdifferential is unique, the generalized derivative $T$ need not be.

**Example 4.8.** (Nonuniqueness and failure of intersections) Let $S : \mathbb{R}^2 \supseteq \mathbb{R}^2$ be defined by $S(x, y) = \{x\} \times \mathbb{R}$. Let $T_1, T_2 : \mathbb{R}^2 \to \mathbb{R}^2$ be defined by $T_1(x, y) = (x, y)$ and $T_2(x, y) = (x, 0)$. It is clear that $S$ is (pseudo) strictly $T_1$-differentiable and (pseudo) strictly $T_2$-differentiable at all points, but it is not (pseudo) $(T_1 \cap T_2)$-differentiable anywhere.

The positively homogeneous map $T : \mathbb{R}^n \supseteq \mathbb{R}^m$ defined from the Clarke Jacobian in Theorem 3.9 is defined as the union of linear functions, and thus satisfies $T = -T(-)$. In such a case $T$-differentiability implies $-T(-)$-differentiability for single valued maps. But this need not be the case for set-valued maps.

**Example 4.9.** (Failure of set-valued $-T(-)$-differentiability) Let $S : \mathbb{R} \supseteq \mathbb{R}$ be defined by $S(x) := (-\infty, x]$, and let $T : \mathbb{R} \supseteq \mathbb{R}$ be defined by

$$T(w) = \begin{cases} \{0\} & \text{if } w \leq 0 \\ [-w, w] & \text{if } w \geq 0. \end{cases}$$

Here, $S$ is strictly $T$-differentiable at $x$ for all $x \in \mathbb{R}$, and it is pseudo strictly $T$-differentiable at $x$ for all $x \in \mathbb{R}$. However, $S$ is neither outer (or inner) $-T(-)$-differentiable anywhere, nor pseudo outer (or inner) $-T(-)$-differentiable at $x$ for any $x \in \mathbb{R}$.

We remark that while inner $T$-differentiability is defined so that Proposition 4.4 holds, this definition of inner $T$-differentiability does not satisfy the property that strict $T$-differentiability implies inner $T$-differentiability in general. It actually implies inner $-T(-)$-differentiability. The same holds for pseudo strict $T$-differentiability and pseudo inner $T$-differentiability, or more correctly, pseudo inner $-T(-)$-differentiability. An example where this occurs is the function $S : \mathbb{R} \supseteq \mathbb{R}$ as defined in Example 4.9. Fortunately, inner $T$-differentiability does not play a huge role in this paper.

Much of the current methods for set-valued differentiation are motivated by looking at the tangent cones of the graph of the set-valued map. See the discussion in Chapter 5] on the different forms of set-valued differentiation obtained by taking different kinds of tangent cones of the graph. The notions of semidifferentiability and proto-differentiability are based on this idea. We recall the definitions of semidifferentiability and proto-differentiability from Page 331-332. See also the techniques in Chapter 5]. We now point out the lack of relation between pseudo $T$-differentiability and these methods by observing the finite dimensional case.
Definition 4.10. (Semidifferentiability) For a set-valued map $S : \mathbb{R}^n \rightrightarrows \mathbb{R}^m$, let $\bar{x} \in \text{dom}(S)$, $\bar{y} \in S(\bar{x})$ and $\bar{w} \in \mathbb{R}^n$. If the limit
\[
\lim_{\tau \searrow 0, w \to \bar{w}} \frac{S(\bar{x} + \tau w) - \bar{y}}{\tau}
\]
exists, then we say that it is the semiderivative at $\bar{x}$ for $\bar{y}$ and $\bar{w}$. If the semiderivative exists for every vector $\bar{w} \in \mathbb{R}^n$, then $S$ is semidifferentiable at $\bar{x}$ for $\bar{y}$ with derivative $DS(\bar{x} \mid \bar{y}) : \mathbb{R}^n \rightrightarrows \mathbb{R}^m$ defined by $DS(\bar{x} \mid \bar{y})(\bar{w})$ being equal to the limit defined above.

Definition 4.11. (Proto-differentiability) A mapping $S : \mathbb{R}^n \rightrightarrows \mathbb{R}^m$ is said to be proto-differentiable at $\bar{x}$ for an element $\bar{y} \in S(\bar{x})$ if
\[
DS(\bar{x} \mid \bar{y})(\bar{w}) = \limsup_{\tau \searrow 0, w \to \bar{w}} \frac{S(\bar{x} + \tau w) - \bar{y}}{\tau}
\]
and there exist for each $\bar{z} \in DS(\bar{x} \mid \bar{y})(\bar{w})$ and choice of $\tau_i \searrow 0$ sequences
\[
w_i \to \bar{w} \text{ and } z_i \to \bar{z} \text{ with } z_i \in [S(\bar{x} + \tau_i w_i) - \bar{y}] / \tau_i.
\]

For this paper, it is sufficient to note that semidifferentiability implies proto-differentiability through \[10\] Exercise 8.43 (a)(d).

The definition of semidifferentiability for set-valued maps is not to be confused with the semidifferentiability defined for single-valued maps before Definition \[34\]. Clearly, the limits in the definitions above are cones, and the derivative $DS(\bar{x} \mid \bar{y})$ are both positively homogeneous maps. We present an example where $S : \mathbb{R} \rightrightarrows \mathbb{R}^2$ is not pseudo strictly $DS(\bar{x} \mid \bar{y})$-differentiable at $\bar{x}$ for $\bar{y}$.

Example 4.12. (Semidifferentiability and $T$-differentiability 1) Consider the set-valued map $S : \mathbb{R} \rightrightarrows \mathbb{R}^2$ defined by
\[
S(x) = \begin{cases} 
\{(t, \sqrt{-t}) \mid -x \leq t \leq 0\} \cup \{(x) \times [\sqrt{x}, \infty)\} & \text{if } x \leq 0 \\
\{(t, \sqrt{t}) \mid 0 \leq t \leq x\} \cup \{(x) \times [\sqrt{x}, \infty)\} & \text{if } x \geq 0.
\end{cases}
\]
This map is semidifferentiable at 0 for $\bar{0}$, with semiderivative $DS(0 \mid \bar{0}) : \mathbb{R} \rightrightarrows \mathbb{R}^2$ defined by $DS(0 \mid \bar{0})(w) = \{0\} \times [0, \infty)$ for all $w \in \mathbb{R}$. However, $S$ is not pseudo strictly $DS(0 \mid \bar{0})$-differentiable at 0 for $\bar{0}$, because at any point $(0, \alpha) \in \{0\} \times (0, \infty)$, we can find a neighborhood $U_\alpha$ of $(0, \alpha)$ such that $S(x) \cap U_\alpha$ is $\{(x) \times (0, \alpha)\} \cap U_\alpha$. See Figure \[14\] Since semidifferentiable functions are proto-differentiable, this example also shows the lack of relation between proto-differentiability and $T$-differentiability.

One may expect that if $S$ is $T$-differentiable at $\bar{x}$ for $\bar{y}$, then $DS(\bar{x} \mid \bar{y}) \subset T$. The following example shows that this is not the case.

Example 4.13. (Semidifferentiability and $T$-differentiability 2) Consider $S : \mathbb{R} \rightrightarrows \mathbb{R}$ defined by $S(x) = \{x\}$. Clearly $S$ is pseudo $T$-differentiable at $x$ for any $y \in \mathbb{R}$, where $T : \mathbb{R} \to \mathbb{R}$ is defined by $T(w) = 0$ for all $w \in \mathbb{R}$. But the semiderivative $DS(\bar{x} \mid \bar{y}) : \mathbb{R} \rightrightarrows \mathbb{R}$, or equivalently the proto-derivative, is equal to $S$, which gives $DS(\bar{x} \mid \bar{y}) \not\subset T$ for all $\bar{x}, \bar{y} \in \mathbb{R}$.
In Example 4.12, for any $\alpha > 0$, we can find a neighborhood $U_\alpha$ of the point $(0, \alpha)$ such that the map $S : \mathbb{R} \rightrightarrows \mathbb{R}^2$ satisfies $S(x) \cap U_\alpha = \{x\} \times (-\infty, \infty) \cap U_\alpha$.

5. Calculus of $T$-differentiability

In this section, we prove a chain rule and a sum rule similar to the coderivative calculus in [40, Section 10H], which was first studied in [31]. Let us first introduce the outer norm of a positively homogeneous set-valued map.

**Definition 5.1.** (Outer norm) If $T : X \rightrightarrows Y$ is a positively homogeneous map, then the outer norm of $T$ is

$$|T|^+ := \sup_{|x| \leq 1} \sup_{y \in T(x)} |y| = \sup\{|y| \mid y \in T(x), |x| \leq 1\}.$$ 

Clearly $|T|^+ < \infty$ implies $T(0) = \{0\}$. When $T(0) = \{0\}$, $|T|^+ = \clm T(0 \mid 0) = \clm T(0)$.

Here is a chain rule for $T$-differentiable functions. In the statements of the results in this section, the positively homogeneous map $T_{\bar{x} \rightarrow y}$ refers to a generalized derivative that arises from considering the point $y \in F(\bar{x})$. Other such maps $T$ are similarly defined.

**Theorem 5.2.** (Chain rule) Let $F : X \rightrightarrows Y$, $G : Y \rightrightarrows Z$, and $\bar{z} \in G \circ F(\bar{x})$. Suppose the following conditions hold

1. $F$ is pseudo outer $T_{\bar{x} \rightarrow y}$-differentiable at $\bar{x}$ for $y$ for all $y$ in $G^{-1}(\bar{z}) \cap F(\bar{x})$.
2. $G$ is pseudo strictly $T_{y \rightarrow \bar{z}}$-differentiable at $\bar{z}$ for all $y$ in $G^{-1}(\bar{z}) \cap F(\bar{x})$.
3. The set $G^{-1}(\bar{z}) \cap F(\bar{x}) \subset Y$ is compact.
4. The map $(x, z) \mapsto G^{-1}(z) \cap F(x)$ is outer semicontinuous at $(\bar{x}, \bar{z})$.
5. $\alpha := \sup_{y \in G^{-1}(\bar{z}) \cap F(\bar{x})} \|T_{\bar{x} \rightarrow y}\|^+$ is finite.
6. For all $y \in G^{-1}(\bar{z}) \cap F(\bar{x})$, $T_{y \rightarrow \bar{z}}(0) = \{0\}$, and $\beta$ is finite, where

$$\beta := \sup_{y \in G^{-1}(\bar{z}) \cap F(\bar{x})} \text{lip} T_{y \rightarrow \bar{z}}(0).$$
Then $G \circ F$ is pseudo outer $T$-differentiable at $\bar{x}$ for $\bar{z}$, where $T : X \rightrightarrows Z$ is defined by

$$T := \bigcup_{y \in G^{-1}(\bar{z}) \cap F(\bar{x})} T_{y \to z} \circ T_{\bar{x} \to y}.$$  

The function $G \circ F$ is pseudo strictly $T$-differentiable for $T : X \rightrightarrows Y$ defined in (5.1) if in statement (1), $F$ were pseudo strictly $T_{\bar{x} \to y}$-differentiable at $\bar{x}$ for $y$ instead.

Proof. We shall prove only the result for $F$ being pseudo outer $T$-differentiable. The proof for pseudo strict $T$-differentiability is almost exactly the same. Choose any $\delta > 0$. Since (2) holds, for each $y \in G^{-1}(\bar{z}) \cap F(\bar{x})$, we can find some open convex neighborhoods $V_y'$ of $y$ and $W$ of $\bar{z}$ such that

$$G(y') \cap W \subset G(y'') + T_{y \to z}(y' - y'') + \delta |y' - y''|B$$

for all $y', y'' \in V_y'$.

Next, since (1) holds, for each $y \in G^{-1}(\bar{z}) \cap F(\bar{x})$, we can find open convex neighborhoods $U$ of $\bar{x}$ and $V_y \subset V_y'$ of $y$ such that

$$F(x) \cap V_y \subset [(F(\bar{x}) \cap V_y') + T_{\bar{x} \to y}(x - \bar{x}) + \delta |x - \bar{x}|B] \cap V_y$$

for all $x \in U$.

Since $G^{-1}(\bar{z}) \cap F(\bar{x})$ is compact by (3), there are finitely many $y_i \in G^{-1}(\bar{z}) \cap F(\bar{x})$ such that $G^{-1}(\bar{z}) \cap F(\bar{x}) \subset \bigcup_i V_{y_i}$. By taking finitely many intersections if necessary, the neighborhoods $U$ and $W$ can be assumed to be independent of $y_i$.

Let $V := \bigcup_i V_{y_i}$. Since the map $(x, z) \mapsto G^{-1}(z) \cap F(x)$ is outer semicontinuous at $(\bar{x}, \bar{z})$ by (4), we can reduce $U$ and $W$ if necessary so that $G^{-1}(W) \cap F(U) \subset V$.

This implies that for any $x \in U$,

$$G(F(x)) \cap W = G(F(x) \cap V) \cap W$$

$$= \left( \bigcup_i G(F(x) \cap V_{y_i}) \right) \cap W.$$  

We have

$$G(F(x) \cap V_{y_i}) \cap W$$

$$\subset G([(F(\bar{x}) \cap V_{y_i}') + T_{\bar{x} \to y_i}(x - \bar{x}) + \delta |x - \bar{x}|B] \cap V_{y_i}) \cap W$$

$$\subset G(F(\bar{x}) \cap V_{y_i}') + T_{y_i \to z}(T_{\bar{x} \to y_i}(x - \bar{x}) + \delta |x - \bar{x}|B)$$

$$+ \delta T_{\bar{x} \to y_i}(x - \bar{x}) + \delta |x - \bar{x}|B |B$$

$$\subset G \circ F(\bar{x}) + T_{y_i \to z} \circ T_{\bar{x} \to y_i}(x - \bar{x}) + \delta \beta |x - \bar{x}|B + \delta (\alpha + \delta) |x - \bar{x}|B$$

$$= G \circ F(\bar{x}) + T_{y_i \to z} \circ T_{\bar{x} \to y_i}(x - \bar{x}) + \delta (\alpha + \beta + \delta) |x - \bar{x}|B.$$  

We may assume that $\delta$ is small enough so that $\alpha + \beta + \delta$ is bounded from above by some finite constant $\theta$. Choosing $y_i$ over all $i$ gives

$$\bigcup_i G(F(x) \cap V_{y_i}) \cap W$$

$$\subset G \circ F(\bar{x}) + \left( \bigcup_i T_{y_i \to z} \circ T_{\bar{x} \to y_i}(x - \bar{x}) \right) + \delta \theta |x - \bar{x}|B$$

$$\subset G \circ F(\bar{x}) + \left( \bigcup_{y \in G^{-1}(\bar{z}) \cap F(\bar{x})} T_{y \to z} \circ T_{\bar{x} \to y}(x - \bar{x}) \right) + \delta \theta |x - \bar{x}|B.$$  

This completes the proof of the theorem. □
In Theorem [5.2] we require $G : Y \rightrightarrows Z$ to be pseudo strictly $T$-differentiable for the appropriate $T : Y \rightrightarrows Z$. If $G : Y \rightrightarrows Z$ were pseudo outer $T$-differentiable, then we can still obtain a result for the case where $F : X \rightrightarrows Y$ is single-valued.

**Proposition 5.3.** (Chain rule) Let $f : X \to Y$ and $G : Y \rightrightarrows Z$, $\bar{y} = f(\bar{x})$, and $\bar{z} \in G(\bar{y})$. Suppose the following conditions hold

1. $f$ is $T_{\bar{z}\to\bar{y}}$-differentiable at $\bar{x}$ for $\bar{y}$.
2. $G$ is pseudo outer $T_{\bar{y}\to\bar{z}}$-differentiable at $\bar{y}$ for $\bar{z}$.
3. $|T_{\bar{z}\to\bar{y}}|^+$ is finite.
4. $T_{\bar{y}\to\bar{z}}(\mathbf{0}) = \{\mathbf{0}\}$, and $\text{lip} T_{\bar{y}\to\bar{z}}(\mathbf{0})$ is finite.

Then $G \circ f$ is pseudo outer $T$-differentiable at $\bar{x}$ for $\bar{z}$, where $T : X \rightrightarrows Z$ is defined by $T = T_{\bar{y}\to\bar{z}} \circ T_{\bar{z}\to\bar{y}}$.

**Proof.** Choose some $\delta > 0$. By condition (1), we can find a neighborhood $U$ of $\bar{x}$ such that

$$f(x) \in f(\bar{x}) + T_{\bar{z}\to\bar{y}}(x - \bar{x}) + \delta|x - \bar{x}|B$$

for all $x \in U$. Let $V$ be such that $f(\bar{x}) + T_{\bar{z}\to\bar{y}}(x - \bar{x}) + \delta|x - \bar{x}|B \subset V$ for all $x \in U$. By (2), we can shrink $U$ and $V$ if necessary so that there is a neighborhood $W$ of $\bar{z}$ such that

$$G(y) \cap W \subset G(\bar{y}) + T_{\bar{y}\to\bar{z}}(y - \bar{y}) + \delta|y - \bar{y}|B$$

for all $y \in V$.

A calculation similar to (5.2) concludes the proof. \hfill \square

From the chain rule, we can infer a sum rule.

**Corollary 5.4.** (Sum rule) Let $S_i : X \rightrightarrows Y$ for $i = 1, \ldots, p$, and $\bar{y} \in \bigcap_{i=1}^p S_i(\bar{x})$. Define $F : X \rightrightarrows Y^p$ by $F(x) = (S_1(x), \ldots, S_p(x))$, and define $g : Y^p \to Y$ to be the linear map mapping to the sum of the $p$ elements in $Y^p$. Suppose the following conditions hold.

1. $S_i$ is pseudo outer $T_{\bar{x}\to y_i}$-differentiable at $\bar{x}$ for $y_i$ whenever $y_i \in S_i(\bar{x})$ and $y_1 + \cdots + y_p = \bar{y}$.
2. The set $\{ (y_1, \ldots, y_p) \mid y_i \in S_i(\bar{x}), y_1 + \cdots + y_p = \bar{y} \} \subset Y^p$ is compact.
3. The map $(x, y) \mapsto g^{-1}(y) \cap F(x)$ is outer semicontinuous at $(\bar{x}, \bar{y})$.
4. $\alpha_i := \sup_{y_i \in S_i(\bar{x})} |T_{\bar{x}\to y_i}|$ is finite for each $i = 1, \ldots, p$. Here, $\Pi : Y^p \to Y$ is the projection onto the $i$th coordinate.

Then $g \circ F : X \rightrightarrows Y$, which is the sum of the maps $S_i$, is $T$-differentiable at $\bar{x}$ for $\bar{y}$, where $T : X \rightrightarrows Y$ is defined by

$$T := \bigcup_{y_i \in S_i(\bar{x})} \left( \sum_{y_1 + \cdots + y_p = \bar{y}} T_{\bar{x}\to y_i} \right).$$

The function $g \circ F$ is pseudo strictly $T$-differentiable for $T : X \rightrightarrows Y$ defined in (5.3) if in statement (1), $S_i$ were pseudo strictly $T_{\bar{x}\to y_i}$-differentiable at $\bar{x}$ for $y_i$ instead.

**Proof.** For $y_i \in S_i(\bar{x})$ for all $i$, define $T_{(y_1, \ldots, y_p)} : X \rightrightarrows Y^p$ by

$$T_{(y_1, \ldots, y_p)}(w) := (T_{\bar{x}\to y_1}(w), \ldots, T_{\bar{x}\to y_p}(w)).$$

Condition (1) implies that the map $F$ is pseudo outer $T_{(y_1, \ldots, y_p)}$-differentiable at $\bar{x}$ for $(y_1, \ldots, y_p)$. We now proceed to apply the chain rule in Theorem [5.2]. Since $g$ is a linear function, the conditions for $g$ needed for the chain rule are satisfied. The
rest of the conditions in this result are just the appropriate conditions in the chain rule rephrased. The case of pseudo strict $T$-differentiability is similar. □

Note that we have focused on pseudo (outer/strict) $T$-differentiability so far in this section. The relation between pseudo (strict/outer/inner) $T$-differentiability and (strict/outer/inner) $T$-differentiability is illustrated by the following theorem. We say that $S : X \to Y$ is locally compact around $\bar{x} \in \text{dom}(F)$ if there is a neighborhood $O$ of $\bar{x}$ and a compact set $C \subset Y$ such that $S(O) \subset C$.

**Theorem 5.5.** ($T$-differentiability from pseudo $T$-differentiability) Let $S : D \to Y$ be a closed-valued outer semicontinuous map on a closed domain $D \subset X$. Suppose $S$ is locally compact around $\bar{x} \in D$. Then $S$ is outer $T$-differentiable at $\bar{x}$ if and only if $S$ is pseudo outer $T$-differentiable at $\bar{x}$ for all $\bar{y} \in S(\bar{x})$.

An analogous statement holds for (strict/inner) $T$-differentiability and pseudo (strict/inner) $T$-differentiability.

**Remark 5.6.** In fact, the hypothesis of outer semicontinuity in Theorem 5.5 can be weakened: We can assume that $S$ is closed at $\bar{x}$: For every $y \notin S(\bar{x})$, there are neighborhoods $U$ of $\bar{x}$ and $V$ of $y$ such that $S(x) \cap V = \emptyset$ for all $x \in U$. If $S$ is outer semicontinuous, then $\text{gph}(S)$ is closed by [4, Proposition 1.4.8], which implies that $S$ is closed at $\bar{x}$. The proof of Theorem 5.5 can be easily adapted from the proof of [32, Theorem 1.42], which traces its roots in the finite dimensional case to [38].

Other calculus rules that are important are the Cartesian product of set-valued maps, and rules for unions. These two operations are simple to formulate and prove. For intersections of set-valued maps, we feel it is more effective to look at maps, and rules for unions. These two operations are simple to formulate and prove.

6. The Mordukhovich criterion

As we have seen in Section 4, the Aubin property gives a sharper analysis for the Lipschitz continuity of set-valued maps. An effective tool for calculating the graphical modulus (for the Aubin property) is the coderivative defined in Definition 6.2, which is a generalization of the adjoint linear operator of linear functions. Coderivatives enjoy an effective calculus, and can be easily calculated for set-valued maps whose graphs are defined by smooth maps. The relationship between the Aubin property and the coderivatives is referred to as the Mordukhovich criterion in [40]. For a history of the Mordukhovich criterion, see the bibliography in [40], which in turn cited [12, 20, 24, 29, 42], and also Commentaries 1.4.6–1.4.9, 4.5.2 and 4.5.6 of [32]. The aim of this section is to show that coderivatives in fact give directional behavior that is captured in the language of pseudo strict $T$-differentiability.

We now recall the classical definition of the normal cones and coderivatives in finite dimensions, which were first introduced in [27] and [28] respectively.

**Definition 6.1.** [27] (Normals) Let $C \subset \mathbb{R}^n$ and $\bar{x} \in C$. A vector $v$ is normal to $C$ at $\bar{x}$ in the regular sense, or a regular normal, written $v \in \mathcal{N}_C(\bar{x})$, if

$$\langle v, x - \bar{x} \rangle \leq o(|x - \bar{x}|) \quad \text{for} \quad x \in C.$$  

It is normal to $C$ at $\bar{x}$ in the general sense, or simply a normal vector, written $v \in \mathcal{N}_C(\bar{x})$, if there are sequences $x_i \to_C \bar{x}$ and $v_i \to v$ with $v_i \in \mathcal{N}_C(x_i)$. 

Definition 6.2. (Coderivatives) Consider a mapping $S : \mathbb{R}^n \rightrightarrows \mathbb{R}^m$, a point $\bar{x} \in \text{dom}(S)$ and $\bar{y} \in S(\bar{x})$. The coderivative at $\bar{x}$ for $\bar{y}$ is the mapping $D^*S(\bar{x} \mid \bar{y}) : \mathbb{R}^m \rightrightarrows \mathbb{R}^n$ defined by

$$v \in D^*S(\bar{x} \mid \bar{y})(z) \iff (v, -z) \in N_{\text{gph}(S)}(\bar{x}, \bar{y}).$$

In the case where $S$ is a smooth map, the coderivative $D^*S(\bar{x} \mid S(\bar{x}))$ is the adjoint of the derivative mapping there.

Next, we recall the definition of the regular subdifferential and general subdifferential, which are important in the proof in the main result of this section.

Definition 6.3. (Subdifferentials) Consider a function $f : \mathbb{R}^n \to \mathbb{R}$ and a point $\bar{x} \in \mathbb{R}^n$. For a vector $v \in \mathbb{R}^n$,

(a) $v$ is a regular subgradient of $f$ at $\bar{x}$, written $v \in \partial f(\bar{x})$, if

$$f(x) - f(\bar{x}) - \langle v, x - \bar{x} \rangle \leq 0 \text{ for all } x \in \mathbb{R}^n.$$

(b) $v$ is a (general) subgradient of $f$ at $\bar{x}$, written $v \in \partial f(\bar{x})$, if there are sequences $x_i \to \bar{x}$ and $v_i \to \partial f(x_i)$ with $v_i \to v$ and $f(x_i) \to f(\bar{x})$.

(c) The sets $\partial f(\bar{x})$ and $\partial f(\bar{x})$ are the regular subdifferential (or Fréchet subgradient) and the (general) subdifferential (or limiting subdifferential, or Mordukhovich subdifferential) at $\bar{x}$ respectively.

We now present our main result of this section.

Theorem 6.4. (Mordukhovich criterion revisited) Consider $S : \mathbb{R}^n \rightrightarrows \mathbb{R}^m$, $\bar{x} \in \text{dom}(S)$ and $\bar{y} \in S(\bar{x})$. Suppose $\text{gph}(S)$ is locally closed at $(\bar{x}, \bar{y})$. If $D^*S(\bar{x} \mid \bar{y})(0) = \{0\}$, or equivalently, $|D^*S(\bar{x} \mid \bar{y})| < \infty$, then $S$ is pseudo strictly $T$-differentiable at $\bar{x}$ for $\bar{y}$, where $T : \mathbb{R}^n \rightrightarrows \mathbb{R}^m$ is defined by

$$T(w) = \kappa(w) \mathbb{B}^m,$$

where $\kappa : \mathbb{R}^n \to \mathbb{R}_+$ is defined by

$$\kappa(w) := \max \{ \langle -v, w \rangle \mid v \in D^*S(\bar{x} \mid \bar{y}) \mathbb{B}^m \} = \max \{ \langle -v, w \rangle \mid (v, -z) \in N_{\text{gph}(S)}(\bar{x}, \bar{y}) \text{ for some } |z| \leq 1 \}.$$

The assumptions of Theorem 6.4 are the same as that of the Mordukhovich Criterion as stated in [10] Theorem 9.40. The Mordukhovich criterion establishes the equivalence between the Aubin property (with graphical modulus $\kappa := \max_{|w| \leq 1} \kappa(w)$) and the outer norm of the coderivative. Theorem 6.4 shows that the worst case Lipschitzian behavior need not occur in all directions.

Proof. (of Theorem 6.4) We highlight only the parts we need to add to the proof of sufficiency as given in [10] Theorem 9.40, though with some changes to the variable names. Let $\bar{k} = |D^*S(\bar{x} \mid \bar{y})|^+$. By the definition of $\bar{k}$ and the coderivatives, for any $\theta > 0$, there exists $\delta_0 > 0$ and $\epsilon_0 > 0$ for which

$$N_{\text{gph}(S)}(\bar{x}, \bar{y}) \cap (\mathbb{R}^n \times \mathbb{B}^m) \subset (\bar{k} + \theta) \mathbb{B}^n \times \mathbb{B}^m \text{ for all } \bar{x} \in \mathbb{B}(\bar{x}, \delta_0), \bar{y} \in \mathbb{B}(\bar{y}, \epsilon_0).$$

(The above statement is just [10] 9(22)) rephrased.) The mapping to normal cones is outer semicontinuous, so

$$N_{\text{gph}(S)}(\bar{x}, \bar{y}) \subset [((\bar{k} + \theta) \mathbb{B}^n \times \mathbb{B}^m) \cap N_{\text{gph}(S)}(\bar{x}, \bar{y})] + \theta \mathbb{B}^{n+m} \text{ for all } \bar{x} \in \mathbb{B}(\bar{x}, \delta_0), \bar{y} \in \mathbb{B}(\bar{y}, \epsilon_0).$$

(6.1)
Define the map \( d_\tilde{g}(x) : \mathbb{R}^n \to \mathbb{R} \) by \( d_\tilde{g}(x) := d(\tilde{y}, S(x)) \). In their proof, the condition in [10, 9(23)] can be written more precisely as:

\[
(\text{6.2}) \quad \begin{cases} 
\text{if } v \in \partial d_\tilde{g}(\tilde{x}) \text{ with } |\tilde{x} - \bar{x}| \leq \delta_0 \\
\text{and } d_\tilde{g}(\tilde{x}) + |\tilde{y} - \bar{y}| \leq \epsilon_0, \text{ then } \\
\text{there exists } z \in \mathbb{B} \text{ with } (v, -z) \in N_{\text{gph}(S)}(\tilde{x}, \tilde{y}),
\end{cases}
\]

where \( \tilde{y} \) is any point of \( S(\tilde{x}) \) nearest to \( \tilde{y} \), that is \( |\tilde{y} - \bar{y}| = d_\tilde{g}(\tilde{x}) \). Moving on, they proved that the map \( (x, y) \mapsto d(y, S(x)) \) is Lipschitz continuous near \( (\bar{x}, \bar{y}) \), or more precisely, there exists some \( \lambda > 0 \) and \( \mu > 0 \) such that

\[
(\text{6.3}) \quad d(y, S(x)) \leq \lambda(|x - \bar{x}| + |y - \bar{y}|) \text{ when } |x - \bar{x}| \leq \mu \text{ and } |y - \bar{y}| \leq \mu.
\]

Furnished with this, we can choose \( \delta > 0 \) and \( \epsilon > 0 \) small enough that \( 2\delta \leq \min\{\mu, \epsilon_0\} \), \( \epsilon \leq \min\{\mu, \epsilon_0/2\} \) and \( \lambda(2\delta + \epsilon) \leq \epsilon_0/2 \). If \( v \in \partial d_\tilde{g}(\tilde{x}) \), \( |\tilde{x} - \bar{x}| \leq 2\delta \) and \( |\tilde{y} - \bar{y}| \leq \epsilon \), then by (6.3), we have

\[
d_\tilde{g}(\tilde{x}) \leq \lambda(|\tilde{x} - \bar{x}| + |\tilde{y} - \bar{y}|) \leq \lambda(2\delta + \epsilon) \leq \frac{\epsilon_0}{2}.
\]

Formula (6.2) then tells us that for any \( v \in \partial d_\tilde{g}(\tilde{x}) \), there exists some \( z \in \mathbb{B} \) such that \( (v, -z) \in N_{\text{gph}(S)}(\tilde{x}, \tilde{y}) \).

By (6.1), there is some \( (\tilde{v}, -\tilde{z}) \in N_{\text{gph}(S)}(\bar{x}, \bar{y}) \) such that \( |(\tilde{v}, -\tilde{z}) - (v, -z)| \leq \theta \).

This gives \( \tilde{v} \in D^* S(\bar{x} \mid \bar{y})(1 + \theta)\mathbb{B}^{m} \), or \( \frac{1}{1+\theta} \tilde{v} \in D^* S(\bar{x} \mid \bar{y})\mathbb{B}^{m} \). Further arithmetic gives \( |v - \frac{1}{1+\theta} \tilde{v}| \leq |v - \tilde{v}| + |\tilde{v} - \tilde{v}|-\theta(1+\frac{1}{1+\theta}) \leq (1+\frac{1}{1+\theta})^m \). So \( v \in D^* S(\bar{x} \mid \bar{y})\mathbb{B}^{m} \).

Let \( \tilde{\theta} \) be \( \theta(1+\frac{1}{1+\theta}) \). We thus have \( \partial d_\tilde{g}(\tilde{x}) \subset D^* S(\bar{x} \mid \bar{y})\mathbb{B} + \tilde{\theta}\mathbb{B} \).

The function \( d_\tilde{g}(\cdot) \) is Lipschitz, so the Clarke subdifferential equals \( \text{conv}(\partial d_\tilde{g}(\cdot)) \) in \( \mathbb{B}(\bar{y}, \epsilon) \).

Choose any two points \( x, x' \in \mathbb{B}(\bar{x}, \delta) \). By the nonsmooth mean value theorem (Theorem 5.3), we have \( d_\tilde{g}(x) - d_\tilde{g}(x') = \langle v, x - x' \rangle \) for some \( v \in \partial C d_\tilde{g}(x) = \text{conv}(\partial d_\tilde{g}(x)) \), where \( x = \tau x + (1 - \tau)x' \) for some \( \tau \in (0, 1) \). Now,

\[
\langle v, x - x' \rangle \leq \max \{ \langle \tilde{v}, x - x' \rangle \mid \tilde{v} \in \partial C d_\tilde{g}(x) \} \leq \max \{ \langle \tilde{v}, x - x' \rangle \mid \tilde{v} \in D^* S(\bar{x} \mid \bar{y})\mathbb{B} + \tilde{\theta}\mathbb{B} \} = \kappa(x' - x) + \tilde{\theta}|x' - x|.
\]

This can be rephrased as \( d_\tilde{g}(x') \geq d_\tilde{g}(x) - \kappa(x' - x) - \tilde{\theta}|x' - x| \). As \( \tilde{y} \) varies over all points in \( \mathbb{B}(\bar{y}, \epsilon) \), this readily gives \( S(x') \cap \mathbb{B}(\bar{y}, \epsilon) \subset S(x) + T(x' - x) + \tilde{\theta}|x' - x|\mathbb{B}^m \), which is what we seek to prove.

\[\square\]

Rockafellar [38] established the relationship between the Aubin property of \( S \) at \( \bar{x} \) and the Lipschitz continuity properties of \( d_\tilde{g}(\cdot) \). (See [10] Exercise 9.37.)

The key to the proof of Theorem 6.3 is that the nonsmooth mean value theorem on \( d_\tilde{g}(\cdot) \) gives us more information on the continuity properties of \( S \).

We close this section with a remark on Theorem 6.3.

Remark 6.5. (More precise \( T \)-differentiability) Suppose \( S : \mathbb{R}^n \rightrightarrows \mathbb{R}^m \), and \( \bar{y} \in S(\bar{x}) \). To obtain a better positively homogeneous map \( T : \mathbb{R}^n \rightrightarrows \mathbb{R}^m \) than the one stated in Theorem 6.3, one applies Theorem 6.3 on the map \( g \circ S + f : \mathbb{R}^n \rightrightarrows \mathbb{R}^m \), where \( f : \mathbb{R}^n \to \mathbb{R}^m \) and \( g : \mathbb{R}^m \to \mathbb{R}^m \) are linear maps and \( g \) is invertible. This approach is equivalent to looking at the normal cones of \( \text{gph}(g \circ S + f) \), which can also be obtained by performing the linear map \( (x, y) \mapsto (x, g(y) + f(x)) \) on \( \text{gph}(S) \subset \mathbb{R}^n \times \mathbb{R}^m \). By appealing to the calculus rules in Section 5, this gives
another $\tilde{T} : \mathbb{R}^n \rightrightarrows \mathbb{R}^m$ for which $S$ is pseudo strictly $\tilde{T}$-differentiable. If we choose finitely many $\{(f_i, g_i)\}_{i}$, then we can define $T' : \mathbb{R}^n \rightrightarrows \mathbb{R}^m$ by

$$T'(w) = \tilde{T}_i(w), \text{ where } i \text{ is determined uniquely by } w.$$ 

It is easy to see that $S$ is $T'$-differentiable at $\bar{x}$ for $\tilde{y}$.

For a semialgebraic set-valued map $S : X \rightrightarrows \mathbb{R}^m$, where $X \subset \mathbb{R}^n$ (i.e., a set-valued map whose graph in $\mathbb{R}^n \times \mathbb{R}^m$ is a finite union of sets defined by finitely many polynomial inequalities), the approach in Remark 6.5 was used in [11] to prove that for all $x \in X$ outside a set of smaller dimension than $X$, given any $y \in S(x)$, we can find a linear map $T : \mathbb{R}^n \to \mathbb{R}^m$ such that $S$ is pseudo strictly $T$-differentiable at $x$ for $y$. Note however, as illustrated in Example 6.8 that the linear map may not be unique.

7. Metric regularity and open covering

For $S : X \rightrightarrows Y$, it is well known that the Aubin property of $S^{-1}$ is related to the metric regularity and open covering properties of $S$. In this section, we study metric regularity and open covering in a more axiomatic manner with the help of $T$-differentiability, proving new relations in these subjects. We caution that for much of this section, we need $T : Y \rightrightarrows X$ instead of $T : X \rightrightarrows Y$.

We begin with our definitions of generalized metric regularity and open covering.

**Definition 7.1.** ($T$-metric regularity) Let $X$ and $Y$ be Banach spaces, $S : X \rightrightarrows Y$ be a set-valued map and $T : Y \rightrightarrows X$ be positively homogeneous. We say that $S$ is $T$-metrically regular at $(\bar{x}, \bar{y}) \in \text{gph}(S)$ if for any $\delta > 0$, there exist neighborhoods $V$ of $\bar{x}$ and $W$ of $\bar{y}$ and $r > 0$ such that, for any $x \in V$ and $A \subset rB$, (or equivalently, for any set $A \subset rB$ containing exactly one element),

$$(7.1) \quad y \in [S(x) + A] \cap W \text{ implies } x \in S^{-1}(y) + (T + \delta)(A).$$

**Definition 7.2.** ($T$-open covering)Let $X$ and $Y$ be Banach spaces, $S : X \rightrightarrows Y$ be a set-valued map and $T : Y \rightrightarrows X$ be positively homogeneous. S is a $T$-open covering at $(\bar{x}, \bar{y}) \in \text{gph}(S)$ if for any $\delta > 0$, there exist neighborhoods $V$ of $\bar{x}$ and $W$ of $\bar{y}$ and $r > 0$ such that, for any $x \in V$ and any set $A \subset rB$ (or equivalently, for any set $A \subset rB$ containing exactly one element),

$$(7.2) \quad |S(x) + A| \cap W \subset S(x + (T + \delta)(A)).$$

Open covering is sometimes known as linear openness. Setting $T(w) := \kappa|w|B$ in both cases reduce the above definitions to the classical definitions of metric regularity and open covering with modulus $\kappa$. Metric regularity with modulus $\kappa$ is often written compactly as: For all $\kappa' > \kappa$, there exists neighborhoods $V$ of $\bar{x}$ and $W$ of $\bar{y}$ such that

$$x \in V, y \in W \text{ implies } d(x, S^{-1}(y)) \leq \kappa'd(y, S(x)).$$

We have our following theorem generalizing the classical equivalence of pseudo strict $T$-differentiability, $T$-metric regularity and $T$-open covering.

**Theorem 7.3.** ($T$-metric regularity and $T$-openness) Let $X$ and $Y$ be Banach spaces and $T : Y \rightrightarrows X$ be a positively homogeneous map. For $S : X \rightrightarrows Y$, the following are equivalent:

1. (MR) $S$ is $T(-\cdot)$-metric regular at $(\bar{x}, \bar{y}) \in \text{gph}(S)$.
2. (OC) $S$ is a $(-T(-\cdot))$-open covering at $(\bar{x}, \bar{y}) \in \text{gph}(S)$. 

(IT) $S^{-1}$ is pseudo strictly $T$-differentiable at $\bar{y}$ for $\bar{x}$.

Proof. We first note that $x \in S^{-1}(y') \cap V$ can be rewritten as $x \in V$, $y' \in S(x)$, so (IT) is equivalent to: For any $\delta > 0$, we can find neighborhoods $V$ of $\bar{x}$ and $W$ of $\bar{y}$ such that

$$x \in V, y' \in S(x), y \in W, y' \in \bar{y}$$ implies $x \in S^{-1}(y) + (T + \delta)(y' - y)$.

Next, take the set $A$ to be $A = \{ y - y' \}$. The condition $y \in [S(x) + A] \cap W$ is equivalent to (2) and (3). The definition of $T(\cdot, \cdot)$-metric regularity can be written as: For any $\delta > 0$, we can find a neighborhood $V$ of $\bar{x}$ and $r > 0$ such that

$$x \in V, y' \in S(x), y \in \mathbb{B}(\bar{y}, r)$$ implies $x \in S^{-1}(y) + (T + \delta)(-A)$.

We first show that (IT) implies (MR). Suppose (7.3) holds for $W = \mathbb{B}(\bar{y}, r')$. If $r = \frac{r'}{\delta}$, then $y \in \mathbb{B}(\bar{y}, r)$ and $A \subset \mathbb{B}(0, r)$ implies that $y' \in \mathbb{B}(\bar{y}, 2r) = \mathbb{B}(\bar{y}, \frac{2r'}{\delta})$. Therefore the formula in (7.3) holds for $r = \frac{r'}{\delta}$.

Next, we show that (MR) implies (IT). Suppose (7.4) holds. If $y' \in \mathbb{B}(\bar{y}, \frac{r}{\delta})$, then $y - y' \in \mathbb{B}(0, r)$, or $A \subset \mathbb{B}(0, r)$. This means that (7.4) holds for $W = \mathbb{B}(\bar{y}, \frac{r}{\delta})$.

For the equivalence of (OC) and (MR), note that (OC) is equivalent to modifying the formula (5) in (7.4) to the equivalent condition $y \in S(x - (T + \delta)(y' - y))$. □

We now look at the connection between pseudo $T$-outer differentiability and metric subregularity. For more on metric subregularity, we refer the reader to [13].

We define $T$-metric subregularity as follows.

**Definition 7.4.** $(T$-metric subregularity) Let $X$ and $Y$ be Banach spaces, $S : X \rightrightarrows Y$ be a set-valued map, and $T : Y \rightrightarrows X$ be positively homogeneous. $S$ is $T$-metrically subregular at $(\bar{x}, \bar{y}) \in \text{gph}(S)$ if for any $\delta > 0$, there exists a neighborhood $V$ of $\bar{x}$ and $r > 0$ such that, for any $A \subset r\mathbb{B}$, (or equivalently, for any set $A \subset r\mathbb{B}$ containing exactly one element.)

$$x \in V, \bar{y} \in S(x) + A$$ implies $x \in S^{-1}(\bar{y}) + (T + \delta)(A)$.

Again, the special case of $T(w) := \kappa|w|\mathbb{B}$, $T$-metric subregularity is equivalent to metric subregularity with modulus $\kappa$, and can be written compactly as: For any $\kappa' > \kappa$, there exists a neighborhood $V$ of $\bar{x}$ such that

$$x \in V$$ implies $d(x, S^{-1}(\bar{y})) \leq \kappa'd(\bar{y}, S(x))$.

Here is a result on the equivalences between $T$-metric subregularity and pseudo outer $T$-differentiability.

**Theorem 7.5.** $(Generalized metric subregularity)$ Let $X$ and $Y$ be Banach spaces, $S : X \rightrightarrows Y$ be a set-valued map, and $T : Y \rightrightarrows X$ be a positively homogeneous set-valued map. The following are equivalent:

(MR') $S$ is $T(\cdot, \cdot)$-metric subregular at $(\bar{x}, \bar{y}) \in \text{gph}(S)$.

(IT') $S^{-1}$ is pseudo outer $T$-differentiable at $\bar{y}$ for $\bar{x}$.
Then the following two conditions are equivalent:

\[ x \in V, y \in S^{-1}(y'), y' - \bar{y} \in rB \implies x \in S^{-1}(\bar{y}) + (T + \delta)(y' - \bar{y}). \]

It is also clear that (MR') can be written in this form with \( A = \{\bar{y} - y'\}. \)

Here is a lemma on pseudo strict \( T \)-differentiability amended from \[10\] Lemma 9.39, which is in turn attributed to \[10\].

**Lemma 7.6.** (Extended formulation of pseudo \( T \)-differentiability) Consider a mapping \( S : X \rightrightarrows Y \), a pair \((\bar{x}, \bar{y}) \in \text{gph}(S)\) where \( \text{gph}(S) \) is locally closed, a set \( D \subset X \) containing \( \bar{x} \), and a positively homogeneous map \( T : X \rightrightarrows Y \). Suppose that there is a \( \delta > 0 \) such that

\[ T(w) \supset \delta|w|B \text{ for all } w \in X. \]

Then the following two conditions are equivalent:

(a) there exist neighborhoods \( V \) of \( \bar{x} \) and \( W \) of \( \bar{y} \) such that

\[ S(x') \cap W \subset S(x) + T(x' - x) \text{ for all } x, x' \in D \cap V. \]

(b) there exist neighborhoods \( V \) of \( \bar{x} \) and \( W \) of \( \bar{y} \) such that

\[ S(x') \cap W \subset S(x) + T(x' - x) \text{ for all } x \in D \cap V, x' \in D. \]

The following two conditions are equivalent as well.

(a') there exist neighborhoods \( V \) of \( \bar{x} \) and \( W \) of \( \bar{y} \) such that

\[ S(x') \cap W \subset S(x) + T(x' - \bar{x}) \text{ for all } x' \in D \cap V. \]

(b') there exists a neighborhood \( W \) of \( \bar{y} \) such that

\[ S(x') \cap W \subset S(x) + T(x' - \bar{x}) \text{ for all } x' \in D. \]

**Proof.** Trivially (b) implies (a), so assume that (a) holds for neighborhoods \( V = B(\bar{x}, \gamma) \) and \( W = B(\bar{y}, \epsilon) \). We will verify that (b) holds for \( V' = B(\bar{x}, \gamma') \) and \( W' = B(\bar{y}, \epsilon') \) when \( 0 < \gamma' < \gamma, 0 < \epsilon' < \epsilon, \) and \( 2\delta \gamma' + \epsilon' \leq \delta \gamma \).

Fix any \( x \in D \cap B(\bar{x}, \gamma') \). Our assumption gives us

\[ S(x') \cap B(\bar{y}, \epsilon') \subset S(x) + T(x' - x) \text{ when } x' \in D \cap B(\bar{x}, \gamma'), \]

and our goal is to demonstrate that this holds also when \( x' \in D \setminus B(\bar{x}, \gamma) \). From applying (a) to \( x' = \bar{x} \), we see that \( \bar{y} \in S(x) + T(x - \bar{x}) \) and consequently \( B(\bar{y}, \epsilon') \subset S(x') + (\delta \gamma' + \epsilon')B \), where \( \delta \gamma' + \epsilon' \leq \delta \gamma - \delta \gamma' \). But \( |x' - x| > \gamma - \gamma' \) when \( x' \in D \setminus B(\bar{x}, \gamma) \), so for such points \( x' \) we have \( \delta \gamma - \delta \gamma' \leq |x' - x| \). Hence

\[ S(x') \cap B(\bar{y}, \epsilon') \subset S(x) + \delta|x' - x|B \subset S(x) + T(x' - x) \]

as required.

We now look at the equivalences of (a') and (b'). Trivially (b') implies (a'), so assume that (a') holds for neighborhoods \( V = B(\bar{x}, \gamma) \) and \( W = B(\bar{y}, \epsilon) \). We can reduce \( \epsilon \) so that \( \epsilon \leq \delta \gamma \). Then \( x' \in D \setminus B(\bar{x}, \gamma) \) implies \( W \subset S(\bar{x}) + T(x' - \bar{x}) \), which gives us what we seek. \( \square \)

If \( T^{-1}(0) = Y \), we have the following equivalent definitions for \( T \)-metric regularity. \( T \)-open covering and \( T \)-metric subregularity that do not require \( A \subset rB \).
Proposition 7.7. (Alternate definition of metric (sub)regularity and openness) Let $S : X \rightrightarrows Y$ and $T : Y \rightrightarrows X$ be set-valued maps, with $T$ positively homogeneous and $T^{-1}(0) = Y$. The following is equivalent to the $T$-metric regularity of $S$ at $(\bar{x}, \bar{y}) \in \text{gph}(S)$:

(MR$_1$) For any $\delta > 0$, there exist neighborhoods $V$ of $\bar{x}$ and $W$ of $\bar{y}$ such that, for any $x \in V$ and $A \subset Y$, (or equivalently, for any set $A \subset Y$ containing exactly one element),

\[ y \in [S(x) + A] \cap W \text{ implies } x \in S^{-1}(y) + (T + \delta)(A). \]

The following is equivalent to the $T$-open covering of $S$ at $(\bar{x}, \bar{y}) \in \text{gph}(S)$:

(OC$_1$) For any $\delta > 0$, there exist neighborhoods $V$ of $\bar{x}$ and $W$ of $\bar{y}$ such that, for any $x \in V$ and any set $A \subset Y$ (or equivalently, for any set $A \subset Y$ containing exactly one element),

\[ |S(x) + A| \cap W \subset S(x + (T + \delta)(A)). \]

The following is equivalent to the $T$-metric subregularity of $S$ at $(\bar{x}, \bar{y}) \in \text{gph}(S)$:

(MR$'_1$) For any $\delta > 0$, there exists a neighborhood $V$ of $\bar{x}$ such that, for any $x \in V$ and $A \subset Y$, (or equivalently, for any set $A \subset Y$ containing exactly one element)

\[ \bar{y} \in S(x) + A \text{ implies } x \in S^{-1}(\bar{y}) + (T + \delta)(A). \]

Proof: The condition $T^{-1}(0) = Y$ ensures that Lemma 7.6 applies. Pseudo strict $T$-differentiability of $S^{-1}$ at $\bar{y}$ for $\bar{x}$ is equivalent to: For any $\delta > 0$, there exists neighborhoods $V$ of $\bar{x}$ and $W$ of $\bar{y}$ such that

\[ \begin{array}{c}
 x \in V, \ y' \in S(x), \ y \in W \implies x \in S^{-1}(y) + (T + \delta)(y' - y).
\end{array} \tag{7.8} \]

The difference here from (7.3) is that the condition $y' \in W$ is superfluous due to Lemma 7.6. We also note that $T(-)(-) -$ metric regularity is rewriting (2) and (3) as $y \in [S(x) + (y - y')] \cap W$ in the above, while $-T(-)(-)$ -open covering is rewriting (2) and (3) as $y \in [S(x) + (y - y')] \cap W$ and (5) as $y \in S(x - (T + \delta)(y' - y))$. Combined with Theorem 7.4, this proves the alternative definitions of $T$-metric regularity and $T$-open covering in (MR$_1$) and (OC$_1$).

For the equivalence of $T$-metric subregularity and (MR$'_1$), the proof is similar. □

We now introduce the definition of $(C, T)$-metric regularity and $(C, T)$-open covering.

Definition 7.8. ($(C, T)$- regularity and covering) Let $X$ and $Y$ be Banach spaces, $S : X \rightrightarrows Y$ be a set-valued map, $T : Y \rightrightarrows X$ be positively homogeneous, and $C \subset Y$ is closed.

(a) $S$ is $(C, T)$-metrically regular at $(\bar{x}, \bar{y}) \in \text{gph}(S)$ if for any $\delta > 0$, there exist neighborhoods $V$ of $\bar{x}$ and $W$ of $\bar{y}$ and $r > 0$ such that, for any $x \in V$ and $t > 0$,

\[ y \in [S(x) + tC] \cap W \text{ implies } x \in S^{-1}(y) + (T + \delta)(tC) \]

for all $t$ such that $tC \subset rB$. 

(b) $S$ is a $(C,T)$-open covering at $(\bar{x},\bar{y}) \in \text{gph}(S)$ if for any $\delta > 0$, there exist neighborhoods $V$ of $\bar{x}$ and $W$ of $\bar{y}$ such that, for any $x \in V$ and $t > 0$,

$$[S(x) + tC] \cap W \subset S(x + (T + \delta)(tC))$$

for all $t$ such that $tC \subset rB$.

One might choose $C$ to be a set different from the unit ball $B$, as this allows one to identify sensitive and less sensitive directions. For example one can choose $C$ as the unit ball under a different norm.

We prove the equivalence of $(C,T)$-metric regularity and $T'$-metric regularity among some $T' : Y \rightrightarrows X$. A similar equivalence also holds for $(C,T)$-open coverings. Therefore one needs only to look at $T$-metric regularity and $T$-open coverings.

**Proposition 7.9.** (Reduction of $(C,T)$-metric regularity to $T$-metric regularity) Let $X$ and $Y$ be Banach spaces, $S : X \rightrightarrows Y$ be a set-valued map, and $T : Y \rightrightarrows X$ be positively homogeneous. Then $S$ is $T'$-metrically regular at $(\bar{x},\bar{y})$ implies that $S$ is $(C,T)$-metrically regular there, where $T' : Y \rightrightarrows X$ is defined by $T'(w) = T(tC)$ for $t = \min\{\lambda \mid w \in \lambda C\}$. The converse holds if $\epsilon B \subset C \subset R\mathbb{B}$ for some $\epsilon, R > 0$.

**Proof.** We recall from the proof of Theorem 7.3, $T'$-metric regularity is equivalent to: For all $\delta > 0$, there is a neighborhood $V$ of $\bar{x}$ and $r > 0$ such that

$$x \in V, y' \in S(x), y \in B(\bar{y}, r), y - y' \in rB \implies x \in S^{-1}(y) + (T' + \delta)(y-y').$$

Next, we note that $(C,T)$-metric regularity is equivalent to: For any $\delta > 0$, there is a neighborhood $V$ of $\bar{x}$ and $r > 0$ such that

$$x \in V, y \in [S(x) + tC] \cap B(\bar{y}, r), tC \subset rB \implies x \in S^{-1}(y) + (T + \delta)(tC),$$

which is in turn equivalent to: For any $\delta > 0$, there is a neighborhood $V$ of $\bar{x}$ and $r > 0$ such that

$$x \in V, y' \in S(x), y \in B(\bar{y}, r), y - y' \in tC, tC \subset rB$$

implies

$$x \in S^{-1}(y) + (T + \delta)(tC).$$

Suppose $S$ is $T'$-metrically regular at $(\bar{x},\bar{y})$. Let $\delta > 0$, $V$ and $r$ be such that

$$x \in V, y' \in S(x), y \in B(\bar{y}, r), y - y' \in tC, tC \subset rB$$

implies

$$x \in S^{-1}(y) + (T + \delta)(tC).$$

For the converse, recall $\epsilon B \subset C \subset R\mathbb{B}$ and examine the condition

$$x \in V, y' \in S(x), y \in B(\bar{y}, r), y - y' \in tC, tC \subset rB$$

implies

$$x \in S^{-1}(y) + (T + \delta)(tC).$$

If $y - y' \in \epsilon B$, then the minimum $t > 0$ such that $y - y' \in tC$ gives $tC \subset rB$, so the condition $tC \subset rB$ is superfluous in (7.10). \qed

8. **Strict $T$-differentiability from outer $T$-differentiability**

Suppose $S : X \rightrightarrows Y$ is such that $\bar{y} \in S(\bar{x})$, $T : X \rightrightarrows Y$ is positively homogeneous, and $S : X \rightrightarrows Y$ is pseudo strictly $T$-differentiable at $\bar{x}$ for $\bar{y}$. Then for any $\delta > 0$, there are neighborhoods $U$ of $\bar{x}$ and $V$ of $\bar{y}$ such that $S$ is pseudo outer $(T + \delta)$-differentiable at $x$ for $y$ for all $x \in U$ and $y \in V \cap S(x)$. The main theorem in this section is to show that the converse holds with additional assumptions.

We now study the relationship between pseudo outer $T$-differentiability and pseudo strict $T$-differentiability. The relation between pseudo (outer/strict) $T$-differentiability and (outer/strict) $T$-differentiability can be obtained from Theorem 5.6. First, here is a lemma on pseudo outer $T$-differentiable functions on a
convex set that is comparable to the second part of [40, Theorem 9.2]. This has been extended from results in [26, 37].

Lemma 8.1. (Pseudo outer $T$-differentiability) Let $D \subset X$ be a convex set, and $S : D \rightharpoonup \mathbb{R}^n$ be a set-valued map satisfying $\hat{y} \in S(x)$. Assume that $T : X \rightharpoonup \mathbb{R}^n$ is a positively homogeneous closed valued set-valued map and $|T|^+ \leq \kappa$ for some $\kappa > 0$. Suppose that

1. $\liminf\limits_{x' \to x} S(x') \supset S(x) \cap \mathbb{B}(\hat{y}, r)$ with respect to $D$ for all $x \in D$ (This is true when $S$ is inner semicontinuous.), and
2. $S$ is pseudo outer $T$-differentiable for all $x \in D$ and $y \in S(x) \cap \mathbb{B}(\hat{y}, r)$.

Then for any $\delta > 0$, $x_0, x_1 \in D$ and $r'$ satisfying $(\kappa + \delta)|x_0 - x_1| + r' < r$, we have $S(x_1) \cap \mathbb{B}(\hat{y}, r') \subset S(x_0) + (T + \delta)(x_1 - x_0)$.

Proof. By the definition of pseudo $T$-differentiability, for any $\delta > 0$, $x \in D$ and $y \in S(x) \cap \mathbb{B}(\hat{y}, r)$, there are neighborhoods $V_{x,y}$ of $x$ and $U_{(\hat{y}, r)}$ of $y$ such that

$S(x') \cap U_{(x,y)} \subset S(x) + (T + \delta)(x' - x)$ for all $x' \in D \cap V_{x,y}$.

Since $S(x) \cap \mathbb{B}(\hat{y}, r)$ is compact, we may choose $y_1, \ldots, y_k \in \mathbb{B}(\hat{y}, r)$ such that

$S(x) \cap \mathbb{B}(\hat{y}, r) \subset \bigcup_{i=1}^k U_{(x,y_i)}$.

Let $U_x$ be the right hand side of the above formula. Clearly, $U_x \cup [\mathbb{B}(\hat{y}, r)]^c$ is an open set containing $S(x)$, where $[\mathbb{B}(\hat{y}, r)]^c$ is the complement of $\mathbb{B}(\hat{y}, r)$. Since $S$ is outer semicontinuous, this implies that there is some neighborhood $V_x \subset \bigcap_{i=1}^k V_{(x,y_i)}$ such that $S(x') \subset U_x \cup [\mathbb{B}(\hat{y}, r)]^c$ for all $x' \in V_x$, which implies that

$S(x') \cap \mathbb{B}(\hat{y}, r) \subset U_x$ for all $x' \in V_x$.

This gives us

$$S(x') \cap \mathbb{B}(\hat{y}, r) \subset S(x) + (T + \delta)(x' - x) \text{ for all } x' \in D \cap V_x.$$  \hspace{1cm} (8.1)

Pick $x_0, x_1 \in D$. For each $t \in (0,1)$, let $x_t = (1-t)x_0 + tx_1$. Formula (8.1) ensures that for each $t \in [0,1]$, there is a ball $\mathbb{B}(x_t, \rho_t)$ such that for each $x' \in D \cap \mathbb{B}(x_t, \rho_t)$, $S(x') \cap \mathbb{B}(\hat{y}, r) \subset S(x_t) + (T + \delta)(x' - x_t)$. Here, $\mathbb{B}$ denotes an open ball. Define

$$\tau := \sup\{t \in [0,1] : \text{ for each } s \in [0,t], S(x_s) \cap \mathbb{B}(\hat{y}, r - (\kappa + \delta)|x_s - x_0|) \subset S(x_0) + (T + \delta)(x_s - x_0)\}.$$

We have $\tau > 0$ because $\rho_0$ is positive. We show first that

$$S(x_r) \cap \mathbb{B}(\hat{y}, r - (\kappa + \delta)|x_r - x_0|) \subset S(x_0) + (T + \delta)(x_r - x_0).$$ \hspace{1cm} (8.2)

By assumption the set $S(x_0)$ is closed, and therefore so is $S(x_0) + (T + \delta)(x_r - x_0)$; let $Q$ be the complement of the latter set. If (8.2) were not true, then $S(x_r)$ would meet the open set $Q \cap \mathbb{B}(\hat{y}, r - (\kappa + \delta)|x_r - x_0|)$, at $\tilde{y}$ say. If $x_0, x_1$ were close enough to $\tilde{x}$, then $\tilde{y} \in S(x_r) \cap \mathbb{B}(\hat{y}, r)$ $\subset$ $S(x_0) + (T + \delta)(x_r - x_0)$, and $\tilde{y}$ would be a point where $S(x_r)$ would $\subset$ $S(x_0) + (T + \delta)(x_r - x_0)$. Therefore, for any $\tilde{r} > 0$, there exists some $\epsilon > 0$ such that

$$|x' - x_r| < \epsilon \text{ implies } S(x') \cap \mathbb{B}(\hat{y}, \tilde{r}) \neq \emptyset.$$

If $\sigma \in (0, \tau)$ is such that $|x_\sigma - x_r| < \epsilon$, then $S(x_\sigma) \cap \mathbb{B}(\hat{y}, \tilde{r}) \neq \emptyset$. If $\tilde{r}$ is such that $\mathbb{B}(\hat{y}, \tilde{r}) \subset \mathbb{B}(\hat{y}, r - (\kappa + \delta)|x_r - x_0|)$, then

$$S(x_0) + (T + \delta)(x_r - x_0) \cap \mathbb{B}(\hat{y}, \tilde{r}) \neq \emptyset.$$

We can find $y_\sigma$ such that $|\hat{y} - y_\sigma| < \tilde{r}$, and $y_\sigma \in S(x_0) + (T + \delta)(x_\sigma - x_0)$. Next, recall that $S(x_0) + (T + \delta)(x_r - x_0) = S(x_0) + (T + \delta)(x_r - x_0) + (T + \delta)(x_\sigma - x_0)$. This means...
that there exists $y_\sigma \in S(x_0) + (T + \delta)(x_\tau - x_0)$ for which $|y_\sigma - y_\sigma| \leq (\kappa + \delta)|x_\tau - x_\sigma|$. Combining the two gives

$$d(\hat{y}, S(x_0) + (T + \delta)(x_\tau - x_0)) \leq |\hat{y} - y_\sigma| + |y_\sigma - y_\sigma| < \hat{r} + (\kappa + \delta)|x_\tau - x_\sigma|.$$  

Since the sum on the right hand side can be made arbitrarily small, we have $\hat{y} \in S(x_0) + (T + \delta)(x_\tau - x_0)$, which contradicts $\hat{y} \not\in Q$. This establishes (8.2).

If $\tau$ were less than 1 there would be $\lambda \in (\tau, 1)$ with $|x_\lambda - x_\tau| < \rho$, such that

$$S(x_\lambda) \cap \tilde{B}(\hat{y}, r - (\kappa + \delta)|x_\lambda - x_0|) \not\subset S(x_\tau) + (T + \delta)(x_\lambda - x_\tau).$$

However, we would then have from (8.2) and the definition of $\rho$, that

$$S(x_\lambda) \cap \tilde{B}(\hat{y}, r - (\kappa + \delta)|x_\lambda - x_0|) \subset S(x_\tau) + (T + \delta)(x_\lambda - x_\tau),$$

and so

$$S(x_\lambda) \cap \tilde{B}(\hat{y}, r - (\kappa + \delta)|x_\lambda - x_0|) \subset [S(x_\tau) + (T + \delta)(x_\lambda - x_\tau)] \cap \tilde{B}(\hat{y}, r - (\kappa + \delta)|x_\lambda - x_0|) = \left(\left[S(x_\tau) \cap \tilde{B}(\hat{y}, r - (\kappa + \delta)|x_\lambda - x_0|)\right] + (T + \delta)(x_\lambda - x_\tau)\right) \cap \tilde{B}(\hat{y}, r - (\kappa + \delta)|x_\lambda - x_0|) \subset (S(x_0) + (T + \delta)(x_\lambda - x_0))$$

$$\subset S(x_0) + (T + \delta)(x_\lambda - x_0),$$

where the inclusion in the last line holds because $x_0, x_\tau$ and $x_\lambda$ are collinear and $T$ is a positively homogeneous convex valued map. This contradicts (8.3), so $\tau$ must be 1. Putting $\tau = 1$ in (8.2) shows that $S(x_1) \cap \tilde{B}(\hat{y}, r - (\kappa + \delta)|x_1 - x_0|) \subset S(x_0) + (T + \delta)(x_1 - x_0)$. The required conclusion follows immediately. \qed

By decreasing $r$ and/or the size of $D$, we deduce that $S$ is pseudo strictly $T$-differentiable at $\hat{x}$ for $\bar{u}$. This is summarized in the theorem below.

**Theorem 8.2.** (Pseudo strict $T$-differentiability from pseudo outer $T$-differentiability) Suppose that $S : D \rightrightarrows \mathbb{R}^n$ and $\bar{y} \in S(\bar{x})$, where $D = \text{dom}(S) \subset X$ is convex. Let $T : X \rightrightarrows \mathbb{R}^n$ a positively homogeneous closed valued set-valued map such that $|T|_+^* \leq \kappa$ for some $\kappa > 0$. If for any $\delta > 0$, there exists open convex sets $U$ of $\bar{x}$ and $V$ of $\bar{y}$ such that

1. $S$ is pseudo outer $(T + \delta)$-differentiable at $y$ whenever $x \in U$, $y \in V$ and $y \in S(x)$,
2. $\liminf_{x \to x'} S(x') \supset S(x) \cap V$ for all $x \in U$. (This is true when $S$ is inner semicontinuous.)

then $S$ is pseudo strictly $T$-differentiable at $\bar{x}$ for $\bar{y}$. Furthermore, the conclusion still holds if we amend condition (1) to:

1a. $S$ is pseudo outer $(T + \delta)$-differentiable at $y$ whenever $x \in U$, $y \in V$ and $y \in S(x)$ but $(x, y) \neq (\bar{x}, \bar{y})$, and
1b. $S$ is outer semicontinuous at $\bar{x}$.

**Proof.** Choose any $\delta > 0$. There are open sets $U$ containing $\bar{x}$ and $B(\bar{y}, r)$ containing $\bar{y}$, such that $S$ is pseudo outer $(T + \delta)$-differentiable at $x$ for $y$ for all $x \in U$,
$y \in \mathbb{B}(\bar{y}, r)$. We can reduce the size of $U$ so that the diameter of $U$, say $d$, satisfies $r - (\kappa + 2\delta)d > 0$. Let $r' = \frac{1}{4}|r - (\kappa + 2\delta)d|$. By Lemma S.1

$$S(x_1) \cap \mathbb{B}(\bar{y}, r') \subset S(x_0) + (T + 2\delta)(x_1 - x_0) \text{ for all } x_0, x_1 \in U \cap D.$$  

Since $\delta$ is arbitrary, $S$ is pseudo strictly $T$-differentiable at $\bar{x}$ for $\bar{y}$ as needed.

To prove the second part, we only need to prove that if both conditions (1a) and (1b) hold, then $S$ is pseudo outer $(T + 2\delta)$-differentiable at $\bar{x}$ for $\bar{y}$. Again, suppose we have neighborhoods $U$ of $\bar{x}$ and $V = \mathbb{B}(\bar{y}, r)$ of $\bar{y}$ respectively such that condition (1a) holds. First, we prove that for all $x \in \mathbb{B}(\bar{x}, \frac{r}{2}) \cap U \cap D$,

$$(8.4) \quad S(x) \cap \mathbb{B} \left( \bar{y}, \frac{r}{2} \right) \subset S(\bar{x}) + (T + 2\delta)(x - \bar{x}).$$

Since $S$ is outer semicontinuous at $\bar{x}$, for any $\epsilon > 0$, there exists a convex combination of $\{x, \bar{x}\}$ arbitrarily close enough to $\bar{x}$, say $\hat{x}$, such that

$$S(\hat{x}) \cap \mathbb{B} \left( \bar{y}, \frac{r}{2} + (\kappa + 2\delta)|x - \bar{x}| \right) \subset S(\bar{x}) + \epsilon \mathbb{B}.$$  

Choose the domain $D'$ to be $\mathbb{B}(\frac{1}{4}(\bar{x} + x), \frac{1}{2}|\bar{x} - x|)$. Both $x, \hat{x}$ are in $D'$, which is convex, and $\frac{r}{2} + \kappa|x - \bar{x}| < r$, so the conditions for Lemma S.1 are satisfied, and we have

$$S(x) \cap \mathbb{B} \left( \bar{y}, \frac{r}{2} \right) \subset S(\hat{x}) + (T + 2\delta)(x - \hat{x}).$$

Then

$$S(x) \cap \mathbb{B} \left( \bar{y}, \frac{r}{2} \right) \cap \mathbb{B} \left( \bar{y}, \frac{r}{2} + (\kappa + 2\delta)|x - \bar{x}| \right) + (T + 2\delta)(x - \hat{x})$$

$$\subset \left[ \left[ S(\hat{x}) \cap \mathbb{B} \left( \bar{y}, \frac{r}{2} + (\kappa + 2\delta)|x - \bar{x}| \right) \right] + (T + 2\delta)(x - \hat{x}) \right]$$

$$\subset \left[ S(\bar{x}) \cap \mathbb{B} \left( \bar{y}, \frac{r}{2} + (\kappa + 2\delta)|x - \bar{x}| \right) + (T + 2\delta)(x - \hat{x}) \right]$$

$$= S(\bar{x}) + (T + 2\delta)(x - \hat{x}) + \epsilon \mathbb{B}.$$  

For any fixed choice of $\epsilon > 0$, we can always choose $\hat{x}$ close enough to $\bar{x}$ so that

$$(T + 2\delta)(x - \hat{x}) \subset (T + 2\delta)(x - \bar{x}) + \epsilon \mathbb{B}$$

$$(T + 2\delta)(x - \hat{x}) \subset (T + 2\delta)(x - \bar{x}) + [(\kappa + 2\delta)|\hat{x} - \bar{x}|] \mathbb{B}.$$  

Since $\epsilon$ is arbitrary, we have $S(x) \cap \mathbb{B}(\bar{y}, \frac{r}{2}) \subset S(\bar{x}) + (T + 2\delta)(x - \bar{x})$. As $x$ is arbitrary in $\mathbb{B}(\bar{x}, \frac{r}{2}) \cap U \cap D$, this means that $S$ is pseudo outer $(T + \delta)$-differentiable at $\bar{x}$ for $\bar{y}$, and we are done. \hfill \square

The corollary below addresses calmness and Lipschitz continuity. We did not explicitly treat the case where either the Lipschitz or calmness moduli could be infinity, but this is still easy.

**Corollary 8.3.** (Calmness and Lipschitz moduli) Suppose that $S : D \equiv \mathbb{R}^n$ is closed valued with $D = \text{dom}(S) \subset X$ and $\bar{y} \in S(\bar{x})$. We have

$$\text{lip} S(\bar{x} | \bar{y}) \geq \limsup_{(x, y) \to (\bar{x}, \bar{y}) \in \text{gph}(S)} \text{clm} S(x | y).$$

If $D$ is locally convex at $\bar{x}$, and there exist neighborhoods $V$ of $\bar{x}$ and $W$ of $\bar{y}$ such that $\text{liminf}_{x' \to \bar{x}, x' \in V} S(x') \supset S(x) \cap W$ for all $x \in V$ (which is the case when $S$ is inner
semicontinuous), then equality holds. If in addition, $S$ is outer semicontinuous at $\bar{x}$, then we also have
\[
\text{lip} S(\bar{x} | \bar{y}) = \limsup_{(x,y) \to (\text{gph}(S) \cap (\bar{x}, \bar{y}))} \text{clm} S(x | y).
\]

In the single-valued case, we have the following corollary.

**Corollary 8.4.** (Single-valued functions) Let $f : D \to \mathbb{R}^n$ be continuous, where $D \subset X$ is convex.

1. Let $T : X \rightrightarrows \mathbb{R}^n$ be a closed-valued positively homogeneous map such that $|T|^+$ is finite. The function $f$ is strictly $T$-differentiable at $\bar{x}$ if and only if for all $\delta > 0$, there is a convex neighborhood $U$ of $\bar{x}$ such that $f$ is $(T + \delta)$-differentiable at all points in $U \cap D$.

2. For any $\bar{x} \in D$,
\[
\text{lip} f(\bar{x}) = \limsup_{x \to \bar{x}} \text{clm} f(x).
\]

**Acknowledgement.** I thank the associate editor and the two anonymous referees for their careful reading and insightful comments which have made the paper much better than it was. I also thank Asen Dontchev, Diethard Klatte, Bernd Kummer, Adrian Lewis and Boris Mordukhovich for comments on a previous version of this paper which have led to improvements, and on the bibliography on the subject. In particular, I thank Lionel Thibault for bringing to my attention the papers [18, 19, 41], and to Alexander Kruger for several suggestions. Much of this paper was written while I was in the Fields Institute in Toronto, which has provided a wonderful environment for working on this paper.
